For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- initial\_tr\_radius** : float  
Initial trust-region radius.
- max\_tr\_radius** : float  
Maximum value of the trust-region radius. No steps that are longer than this value will be proposed.
- eta** : float  
Trust region related acceptance stringency for proposed steps.
- gtol** : float  
Gradient norm must be less than *gtol* before successful termination.

The `minimize_scalar` function supports the following methods:

*minimize\_scalar(method='brent')*

`scipy.optimize.minimize_scalar` (*fun*, *args*=(), *method*='brent', *tol*=None, *options*={'xtol': 1.48e-08, 'brack': None, 'func': None, 'maxiter': 500})

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.minimize_scalar`

**Options**      **maxiter** : int  
                   Maximum number of iterations to perform.  
                   **xtol** : float  
                   Relative error in solution *xopt* acceptable for convergence.

**Notes**

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method.

*minimize\_scalar(method='bounded')*

`scipy.optimize.minimize_scalar` (*fun*, *bounds*=None, *args*=(), *method*='bounded', *tol*=None, *options*={'disp': 0, 'maxiter': 500, 'func': None, 'xatol': 1e-05})

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.minimize_scalar`

**Options**      **maxiter** : int  
                   Maximum number of iterations to perform.  
                   **disp** : bool  
                   Set to True to print convergence messages.  
                   **xatol** : float  
                   Absolute error in solution *xopt* acceptable for convergence.

*minimize\_scalar(method='golden')*

`scipy.optimize.minimize_scalar` (*fun*, *args*=(), *method*='golden', *tol*=None, *options*={'xtol': 1.4901161193847656e-08, 'brack': None, 'func': None, 'maxiter': 5000})

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.minimize_scalar`

**Options**      **maxiter** : int  
                   Maximum number of iterations to perform.  
                   **xtol** : float  
                   Relative error in solution *xopt* acceptable for convergence.

The specific optimization method interfaces below in this subsection are not recommended for use in new scripts; all of these methods are accessible via a newer, more consistent interface provided by the functions above.

General-purpose multivariate methods:

<code>fmin</code> ( <i>func</i> , <i>x0</i> [], <i>args</i> , <i>xtol</i> , <i>ftol</i> , <i>maxiter</i> , ...)	Minimize a function using the downhill simplex algorithm.
<code>fmin_powell</code> ( <i>func</i> , <i>x0</i> [], <i>args</i> , <i>xtol</i> , <i>ftol</i> , ...)	Minimize a function using modified Powell's method.

Continued on next page

Table 5.117 – continued from previous page

<code>fmin_cg(f, x0[, fprime, args, gtol, norm, ...])</code>	Minimize a function using a nonlinear conjugate gradient algorithm.
<code>fmin_bfgs(f, x0[, fprime, args, gtol, norm, ...])</code>	Minimize a function using the BFGS algorithm.
<code>fmin_ncg(f, x0, fprime[, fhess_p, fhess, ...])</code>	Unconstrained minimization of a function using the Newton-CG method.

`scipy.optimize.fmin` (*func*, *x0*, *args*=(), *xtol*=0.0001, *ftol*=0.0001, *maxiter*=None, *maxfun*=None, *full\_output*=0, *disp*=1, *retall*=0, *callback*=None, *initial\_simplex*=None)  
 Minimize a function using the downhill simplex algorithm.

This algorithm only uses function values, not derivatives or second derivatives.

**Parameters**

- func** : callable `func(x,*args)`  
The objective function to be minimized.
- x0** : ndarray  
Initial guess.
- args** : tuple, optional  
Extra arguments passed to `func`, i.e. `f(x,*args)`.
- xtol** : float, optional  
Absolute error in `xopt` between iterations that is acceptable for convergence.
- ftol** : number, optional  
Absolute error in `func(xopt)` between iterations that is acceptable for convergence.
- maxiter** : int, optional  
Maximum number of iterations to perform.
- maxfun** : number, optional  
Maximum number of function evaluations to make.
- full\_output** : bool, optional  
Set to True if `fopt` and `warnflag` outputs are desired.
- disp** : bool, optional  
Set to True to print convergence messages.
- retall** : bool, optional  
Set to True to return list of solutions at each iteration.
- callback** : callable, optional  
Called after each iteration, as `callback(xk)`, where `xk` is the current parameter vector.
- initial\_simplex** : array\_like of shape (N + 1, N), optional  
Initial simplex. If given, overrides `x0`. `initial_simplex[j, :]` should contain the coordinates of the `j`-th vertex of the N+1 vertices in the simplex, where N is the dimension.

**Returns**

- xopt** : ndarray  
Parameter that minimizes function.
- fopt** : float  
Value of function at minimum: `fopt = func(xopt)`.
- iter** : int  
Number of iterations performed.
- funcalls** : int  
Number of function calls made.
- warnflag** : int  
1 : Maximum number of function evaluations made. 2 : Maximum number of iterations reached.
- allvecs** : list  
Solution at each iteration.

See also:

**minimize** Interface to minimization algorithms for multivariate functions. See the ‘Nelder-Mead’ *method* in particular.

*Notes*

Uses a Nelder-Mead simplex algorithm to find the minimum of function of one or more variables.

This algorithm has a long history of successful use in applications. But it will usually be slower than an algorithm that uses first or second derivative information. In practice it can have poor performance in high-dimensional problems and is not robust to minimizing complicated functions. Additionally, there currently is no complete theory describing when the algorithm will successfully converge to the minimum, or how fast it will if it does. Both the *ftol* and *xtol* criteria must be met for convergence.

*References*

[R198], [R199]

*Examples*

```
>>> def f(x):
...     return x**2

>>> from scipy import optimize

>>> minimum = optimize.fmin(f, 1)
Optimization terminated successfully.
    Current function value: 0.000000
    Iterations: 17
    Function evaluations: 34
>>> minimum[0]
-8.8817841970012523e-16
```

`scipy.optimize.fmin_powell` (*func*, *x0*, *args=()*, *xtol=0.0001*, *ftol=0.0001*, *maxiter=None*, *maxfun=None*, *full\_output=0*, *disp=1*, *retall=0*, *callback=None*, *direc=None*)

Minimize a function using modified Powell’s method. This method only uses function values, not derivatives.

- Parameters**
- func** : callable f(x,\*args)  
Objective function to be minimized.
  - x0** : ndarray  
Initial guess.
  - args** : tuple, optional  
Extra arguments passed to func.
  - callback** : callable, optional  
An optional user-supplied function, called after each iteration. Called as `callback(xk)`, where `xk` is the current parameter vector.
  - direc** : ndarray, optional  
Initial direction set.
  - xtol** : float, optional  
Line-search error tolerance.
  - ftol** : float, optional  
Relative error in `func(xopt)` acceptable for convergence.
  - maxiter** : int, optional  
Maximum number of iterations to perform.
  - maxfun** : int, optional  
Maximum number of function evaluations to make.
  - full\_output** : bool, optional

If True, `fopt`, `xi`, `direc`, `iter`, `funcalls`, and `warnflag` are returned.

**disp** : bool, optional  
If True, print convergence messages.

**retall** : bool, optional  
If True, return a list of the solution at each iteration.

**Returns** **xopt** : ndarray  
Parameter which minimizes *func*.

**fopt** : number  
Value of function at minimum: `fopt = func(xopt)`.

**direc** : ndarray  
Current direction set.

**iter** : int  
Number of iterations.

**funcalls** : int  
Number of function calls made.

**warnflag** : int  
*Integer warning flag:*  
1 : Maximum number of function evaluations. 2 : Maximum number of iterations.

**allvecs** : list  
List of solutions at each iteration.

**See also:**

**minimize** Interface to unconstrained minimization algorithms for multivariate functions. See the ‘Powell’ *method* in particular.

**Notes**

Uses a modification of Powell’s method to find the minimum of a function of N variables. Powell’s method is a conjugate direction method.

The algorithm has two loops. The outer loop merely iterates over the inner loop. The inner loop minimizes over each current direction in the direction set. At the end of the inner loop, if certain conditions are met, the direction that gave the largest decrease is dropped and replaced with the difference between the current estimated  $x$  and the estimated  $x$  from the beginning of the inner-loop.

The technical conditions for replacing the direction of greatest increase amount to checking that

- 1.No further gain can be made along the direction of greatest increase from that iteration.
- 2.The direction of greatest increase accounted for a large sufficient fraction of the decrease in the function value from that iteration of the inner loop.

**Examples**

```
>>> def f(x):
...     return x**2
```

```
>>> from scipy import optimize
```

```
>>> minimum = optimize.fmin_powell(f, -1)
Optimization terminated successfully.
      Current function value: 0.000000
      Iterations: 2
      Function evaluations: 18
>>> minimum
array(0.0)
```

```
scipy.optimize.fmin_cg(f, x0, fprime=None, args=(), gtol=1e-05, norm=inf,
                      epsilon=1.4901161193847656e-08, maxiter=None, full_output=0, disp=1,
                      retall=0, callback=None)
```

Minimize a function using a nonlinear conjugate gradient algorithm.

**Parameters**

- f** : callable,  $f(x, *args)$   
Objective function to be minimized. Here  $x$  must be a 1-D array of the variables that are to be changed in the search for a minimum, and  $args$  are the other (fixed) parameters of  $f$ .
- x0** : ndarray  
A user-supplied initial estimate of  $x_{opt}$ , the optimal value of  $x$ . It must be a 1-D array of values.
- fprime** : callable,  $fprime(x, *args)$ , optional  
A function that returns the gradient of  $f$  at  $x$ . Here  $x$  and  $args$  are as described above for  $f$ . The returned value must be a 1-D array. Defaults to None, in which case the gradient is approximated numerically (see *epsilon*, below).
- args** : tuple, optional  
Parameter values passed to  $f$  and  $fprime$ . Must be supplied whenever additional fixed parameters are needed to completely specify the functions  $f$  and  $fprime$ .
- gtol** : float, optional  
Stop when the norm of the gradient is less than  $gtol$ .
- norm** : float, optional  
Order to use for the norm of the gradient ( $-np.Inf$  is min,  $np.Inf$  is max).
- epsilon** : float or ndarray, optional  
Step size(s) to use when  $fprime$  is approximated numerically. Can be a scalar or a 1-D array. Defaults to  $\sqrt{eps}$ , with  $eps$  the floating point machine precision. Usually  $\sqrt{eps}$  is about  $1.5e-8$ .
- maxiter** : int, optional  
Maximum number of iterations to perform. Default is  $200 * \text{len}(x0)$ .
- full\_output** : bool, optional  
If True, return  $f_{opt}$ ,  $func\_calls$ ,  $grad\_calls$ , and  $warnflag$  in addition to  $x_{opt}$ . See the Returns section below for additional information on optional return values.
- disp** : bool, optional  
If True, return a convergence message, followed by  $x_{opt}$ .
- retall** : bool, optional  
If True, add to the returned values the results of each iteration.
- callback** : callable, optional  
An optional user-supplied function, called after each iteration. Called as  $callback(xk)$ , where  $xk$  is the current value of  $x0$ .

**Returns**

- xopt** : ndarray  
Parameters which minimize  $f$ , i.e.  $f(x_{opt}) == f_{opt}$ .
- fopt** : float, optional  
Minimum value found,  $f(x_{opt})$ . Only returned if *full\_output* is True.
- func\_calls** : int, optional

The number of function\_calls made. Only returned if *full\_output* is True.

**grad\_calls** : int, optional  
The number of gradient calls made. Only returned if *full\_output* is True.

**warnflag** : int, optional  
Integer value with warning status, only returned if *full\_output* is True.  
0 : Success.  
1 : The maximum number of iterations was exceeded.  
2 [Gradient and/or function calls were not changing. May indicate] that precision was lost, i.e., the routine did not converge.

**allvecs** : list of ndarray, optional  
List of arrays, containing the results at each iteration. Only returned if *retall* is True.

**See also:**

**minimize** common interface to all *scipy.optimize* algorithms for unconstrained and constrained minimization of multivariate functions. It provides an alternative way to call `fmin_cg`, by specifying `method='CG'`.

**Notes**

This conjugate gradient algorithm is based on that of Polak and Ribiere [R200].

Conjugate gradient methods tend to work better when:

1.  $f$  has a unique global minimizing point, and no local minima or other stationary points,
2.  $f$  is, at least locally, reasonably well approximated by a quadratic function of the variables,
3.  $f$  is continuous and has a continuous gradient,
4.  $f_{\text{prime}}$  is not too large, e.g., has a norm less than 1000,
5. The initial guess,  $x_0$ , is reasonably close to  $f$ 's global minimizing point,  $x_{\text{opt}}$ .

**References**

[R200]

**Examples**

Example 1: seek the minimum value of the expression  $a*u**2 + b*u*v + c*v**2 + d*u + e*v + f$  for given values of the parameters and an initial guess  $(u, v) = (0, 0)$ .

```
>>> args = (2, 3, 7, 8, 9, 10) # parameter values
>>> def f(x, *args):
...     u, v = x
...     a, b, c, d, e, f = args
...     return a*u**2 + b*u*v + c*v**2 + d*u + e*v + f
>>> def gradf(x, *args):
...     u, v = x
...     a, b, c, d, e, f = args
...     gu = 2*a*u + b*v + d # u-component of the gradient
...     gv = b*u + 2*c*v + e # v-component of the gradient
...     return np.asarray((gu, gv))
>>> x0 = np.asarray((0, 0)) # Initial guess.
>>> from scipy import optimize
>>> res1 = optimize.fmin_cg(f, x0, fprime=gradf, args=args)
Optimization terminated successfully.
Current function value: 1.617021
Iterations: 4
Function evaluations: 8
```

```

        Gradient evaluations: 8
>>> res1
array([-1.80851064, -0.25531915])
    
```

Example 2: solve the same problem using the `minimize` function. (This `myopts` dictionary shows all of the available options, although in practice only non-default values would be needed. The returned value will be a dictionary.)

```

>>> opts = {'maxiter' : None,      # default value.
...         'disp' : True,        # non-default value.
...         'gtol' : 1e-5,       # default value.
...         'norm' : np.inf,     # default value.
...         'eps' : 1.4901161193847656e-08} # default value.
>>> res2 = optimize.minimize(f, x0, jac=gradf, args=args,
...                          method='CG', options=opts)
Optimization terminated successfully.
    Current function value: 1.617021
    Iterations: 4
    Function evaluations: 8
    Gradient evaluations: 8
>>> res2.x # minimum found
array([-1.80851064, -0.25531915])
    
```

```

scipy.optimize.fmin_bfgs(f, x0, fprime=None, args=(), gtol=1e-05, norm=inf,
                        epsilon=1.4901161193847656e-08, maxiter=None, full_output=0,
                        disp=1, retall=0, callback=None)
    
```

Minimize a function using the BFGS algorithm.

**Parameters**

- f** : callable f(x,\*args)  
Objective function to be minimized.
- x0** : ndarray  
Initial guess.
- fprime** : callable f'(x,\*args), optional  
Gradient of f.
- args** : tuple, optional  
Extra arguments passed to f and fprime.
- gtol** : float, optional  
Gradient norm must be less than gtol before successful termination.
- norm** : float, optional  
Order of norm (Inf is max, -Inf is min)
- epsilon** : int or ndarray, optional  
If fprime is approximated, use this value for the step size.
- callback** : callable, optional  
An optional user-supplied function to call after each iteration. Called as callback(xk), where xk is the current parameter vector.
- maxiter** : int, optional  
Maximum number of iterations to perform.
- full\_output** : bool, optional  
If True, return foft, func\_calls, grad\_calls, and warnflag in addition to xopt.
- disp** : bool, optional  
Print convergence message if True.
- retall** : bool, optional  
Return a list of results at each iteration if True.

**Returns**

- xopt** : ndarray  
Parameters which minimize f, i.e. f(xopt) == foft.
- foft** : float

Minimum value.  
**gopt** : ndarray  
 Value of gradient at minimum,  $f'(x_{opt})$ , which should be near 0.  
**Bopt** : ndarray  
 Value of  $1/f''(x_{opt})$ , i.e. the inverse hessian matrix.  
**func\_calls** : int  
 Number of function\_calls made.  
**grad\_calls** : int  
 Number of gradient calls made.  
**warnflag** : integer  
 1 : Maximum number of iterations exceeded. 2 : Gradient and/or function calls not changing.  
**allvecs** : list  
*OptimizeResult* at each iteration. Only returned if `retall` is True.

**See also:**

**minimize** Interface to minimization algorithms for multivariate functions. See the ‘BFGS’ *method* in particular.

**Notes**

Optimize the function,  $f$ , whose gradient is given by  $fprime$  using the quasi-Newton method of Broyden, Fletcher, Goldfarb, and Shanno (BFGS)

**References**

Wright, and Nocedal ‘Numerical Optimization’, 1999, pg. 198.

```
scipy.optimize.fmin_ncg(f, x0, fprime, fhess_p=None, fhess=None, args=(), avextol=1e-05,
                        epsilon=1.4901161193847656e-08, maxiter=None, full_output=0, disp=1,
                        retall=0, callback=None)
```

Unconstrained minimization of a function using the Newton-CG method.

**Parameters**

- f** : callable  $f(x, *args)$   
Objective function to be minimized.
- x0** : ndarray  
Initial guess.
- fprime** : callable  $f'(x, *args)$   
Gradient of  $f$ .
- fhess\_p** : callable  $fhess_p(x, p, *args)$ , optional  
Function which computes the Hessian of  $f$  times an arbitrary vector,  $p$ .
- fhess** : callable  $fhess(x, *args)$ , optional  
Function to compute the Hessian matrix of  $f$ .
- args** : tuple, optional  
Extra arguments passed to  $f$ ,  $fprime$ ,  $fhess_p$ , and  $fhess$  (the same set of extra arguments is supplied to all of these functions).
- epsilon** : float or ndarray, optional  
If  $fhess$  is approximated, use this value for the step size.
- callback** : callable, optional  
An optional user-supplied function which is called after each iteration. Called as `callback(xk)`, where  $xk$  is the current parameter vector.
- avextol** : float, optional  
Convergence is assumed when the average relative error in the minimizer falls below this amount.
- maxiter** : int, optional  
Maximum number of iterations to perform.

**full\_output** : bool, optional  
 If True, return the optional outputs.

**disp** : bool, optional  
 If True, print convergence message.

**retall** : bool, optional  
 If True, return a list of results at each iteration.

**Returns**

**xopt** : ndarray  
 Parameters which minimize  $f$ , i.e.  $f(x_{opt}) == f_{opt}$ .

**fopt** : float  
 Value of the function at  $x_{opt}$ , i.e.  $f_{opt} = f(x_{opt})$ .

**fcalls** : int  
 Number of function calls made.

**gcalls** : int  
 Number of gradient calls made.

**hcalls** : int  
 Number of hessian calls made.

**warnflag** : int  
 Warnings generated by the algorithm. 1 : Maximum number of iterations exceeded.

**allvecs** : list  
 The result at each iteration, if `retall` is True (see below).

**See also:**

**minimize** Interface to minimization algorithms for multivariate functions. See the ‘Newton-CG’ *method* in particular.

**Notes**

Only one of `f_hess_p` or `f_hess` need to be given. If `f_hess` is provided, then `f_hess_p` will be ignored. If neither `f_hess` nor `f_hess_p` is provided, then the hessian product will be approximated using finite differences on `f_prime`. `f_hess_p` must compute the hessian times an arbitrary vector. If it is not given, finite-differences on `f_prime` are used to compute it.

Newton-CG methods are also called truncated Newton methods. This function differs from `scipy.optimize.fmin_tnc` because

1. `scipy.optimize.fmin_ncg` is written purely in python using `numpy` and `scipy` while `scipy.optimize.fmin_tnc` calls a C function.
2. `scipy.optimize.fmin_ncg` is only for unconstrained minimization while `scipy.optimize.fmin_tnc` is for unconstrained minimization or box constrained minimization. (Box constraints give lower and upper bounds for each variable separately.)

```
scipy.optimize.fmin_l_bfgs_b(func, x0, fprime=None, args=(), approx_grad=0, bounds=None,
                             m=10, factr=10000000.0, pgtol=1e-05, epsilon=1e-08, iprint=-
                             1, maxfun=15000, maxiter=15000, disp=None, callback=None,
                             maxls=20)
```

Minimize a function `func` using the L-BFGS-B algorithm.

**Parameters**

- func** : callable `f(x,*args)`  
Function to minimise.
- x0** : ndarray  
Initial guess.
- fprime** : callable `fprime(x,*args)`, optional  
The gradient of `func`. If `None`, then `func` returns the function value and the gradient (`f`, `g = func(x, *args)`), unless `approx_grad` is `True` in which case `func` returns only `f`.
- args** : sequence, optional  
Arguments to pass to `func` and `fprime`.
- approx\_grad** : bool, optional  
Whether to approximate the gradient numerically (in which case `func` returns only the function value).
- bounds** : list, optional  
(`min`, `max`) pairs for each element in `x`, defining the bounds on that parameter. Use `None` or `+inf` for one of `min` or `max` when there is no bound in that direction.
- m** : int, optional  
The maximum number of variable metric corrections used to define the limited memory matrix. (The limited memory BFGS method does not store the full hessian but uses this many terms in an approximation to it.)
- factr** : float, optional  
The iteration stops when  $(f^k - f^{k+1}) / \max\{|f^k|, |f^{k+1}|, 1\} \leq \text{factr} * \text{eps}$ , where `eps` is the machine precision, which is automatically generated by the code. Typical values for `factr` are: `1e12` for low accuracy; `1e7` for moderate accuracy; `10.0` for extremely high accuracy. See Notes for relationship to `ftol`, which is exposed (instead of `factr`) by the `scipy.optimize.minimize` interface to L-BFGS-B.
- pgtol** : float, optional  
The iteration will stop when  $\max\{|\text{proj } g_i| \mid i = 1, \dots, n\} \leq \text{pgtol}$  where `pg_i` is the *i*-th component of the projected gradient.
- epsilon** : float, optional  
Step size used when `approx_grad` is `True`, for numerically calculating the gradient
- iprint** : int, optional  
Controls the frequency of output. `iprint < 0` means no output; `iprint = 0` print only one line at the last iteration; `0 < iprint < 99` print also `f` and `|\text{proj } g|` every `iprint` iterations; `iprint = 99` print details of every iteration except `n`-vectors; `iprint = 100` print also the changes of active set and final `x`; `iprint > 100` print details of every iteration including `x` and `g`.
- disp** : int, optional  
If zero, then no output. If a positive number, then this over-rides `iprint` (i.e., `iprint` gets the value of `disp`).
- maxfun** : int, optional  
Maximum number of function evaluations.
- maxiter** : int, optional  
Maximum number of iterations.
- callback** : callable, optional  
Called after each iteration, as `callback(xk)`, where `xk` is the current parameter vector.
- maxls** : int, optional

**Returns**

- x** : array\_like  
Estimated position of the minimum.
- f** : float  
Value of *func* at the minimum.
- d** : dict  
Information dictionary.
  - d['warnflag'] is
    - 0 if converged,
    - 1 if too many function evaluations or too many iterations,
    - 2 if stopped for another reason, given in d['task']
  - d['grad'] is the gradient at the minimum (should be 0 ish)
  - d['funcalls'] is the number of function calls made.
  - d['nit'] is the number of iterations.

`scipy.optimize.fmin_tnc`(*func*, *x0*, *fprime=None*, *args=()*, *approx\_grad=0*, *bounds=None*, *epsilon=1e-08*, *scale=None*, *offset=None*, *messages=15*, *maxCGit=-1*, *maxfun=None*, *eta=-1*, *stepmx=0*, *accuracy=0*, *fmin=0*, *ftol=-1*, *xtol=-1*, *pgtol=-1*, *rescale=-1*, *disp=None*, *callback=None*)

Minimize a function with variables subject to bounds, using gradient information in a truncated Newton algorithm. This method wraps a C implementation of the algorithm.

**Parameters**

- func** : callable `func(x, *args)`  
Function to minimize. Must do one of:
  - 1.Return f and g, where f is the value of the function and g its gradient (a list of floats).
  - 2.Return the function value but supply gradient function separately as *fprime*.
  - 3.Return the function value and set `approx_grad=True`.
 If the function returns None, the minimization is aborted.

**x0** : array\_like  
Initial estimate of minimum.

**fprime** : callable `fprime(x, *args)`, optional  
Gradient of *func*. If None, then either *func* must return the function value and the gradient (`f, g = func(x, *args)`) or *approx\_grad* must be True.

**args** : tuple, optional  
Arguments to pass to function.

**approx\_grad** : bool, optional  
If true, approximate the gradient numerically.

**bounds** : list, optional  
(min, max) pairs for each element in x0, defining the bounds on that parameter. Use None or +/-inf for one of min or max when there is no bound in that direction.

**epsilon** : float, optional  
Used if *approx\_grad* is True. The stepsize in a finite difference approximation for *fprime*.

**scale** : array\_like, optional  
Scaling factors to apply to each variable. If None, the factors are up-low for interval bounded variables and  $1+|x|$  for the others. Defaults to None.

**offset** : array\_like, optional  
Value to subtract from each variable. If None, the offsets are  $(\text{up}+\text{low})/2$  for interval bounded variables and *x* for the others.

**messages** : int, optional  
Bit mask used to select messages display during minimization values defined in the MSGS dict. Defaults to MGS\_ALL.

**disp** : int, optional  
Integer interface to messages. 0 = no message, 5 = all messages

**maxCGit** : int, optional  
Maximum number of hessian\*vector evaluations per main iteration. If `maxCGit == 0`, the direction chosen is -gradient if `maxCGit < 0`, `maxCGit` is set to  $\max(1, \min(50, n/2))$ . Defaults to -1.

**maxfun** : int, optional  
Maximum number of function evaluation. if None, `maxfun` is set to  $\max(100, 10*\text{len}(x0))$ . Defaults to None.

**eta** : float, optional  
Severity of the line search. if  $< 0$  or  $> 1$ , set to 0.25. Defaults to -1.

**stepmx** : float, optional  
Maximum step for the line search. May be increased during call. If too small, it will be set to 10.0. Defaults to 0.

**accuracy** : float, optional  
Relative precision for finite difference calculations. If  $\leq \text{machine\_precision}$ , set to  $\sqrt{\text{machine\_precision}}$ . Defaults to 0.

**fmin** : float, optional  
Minimum function value estimate. Defaults to 0.

**ftol** : float, optional  
Precision goal for the value of *f* in the stopping criterion. If `ftol < 0.0`, `ftol` is set to 0.0 defaults to -1.

**xtol** : float, optional  
Precision goal for the value of *x* in the stopping criterion (after applying *x* scaling factors). If `xtol < 0.0`, `xtol` is set to  $\sqrt{\text{machine\_precision}}$ . Defaults to -1.

**pgtol** : float, optional  
Precision goal for the value of the projected gradient in the stopping criterion (after applying *x* scaling factors). If `pgtol < 0.0`, `pgtol` is set to  $1e-2 * \sqrt{\text{accuracy}}$ . Setting it to 0.0 is not recommended. Defaults to -1.

**rescale** : float, optional

Scaling factor (in log10) used to trigger f value rescaling. If 0, rescale at each iteration. If a large value, never rescale. If < 0, rescale is set to 1.3.

**callback** : callable, optional

Called after each iteration, as `callback(xk)`, where `xk` is the current parameter vector.

**Returns**

**x** : ndarray

The solution.

**nfeval** : int

The number of function evaluations.

**rc** : int

Return code, see below

**See also:**

**minimize** Interface to minimization algorithms for multivariate functions. See the ‘TNC’ *method* in particular.

**Notes**

The underlying algorithm is truncated Newton, also called Newton Conjugate-Gradient. This method differs from `scipy.optimize.fmin_ncg` in that

- 1.It wraps a C implementation of the algorithm
- 2.It allows each variable to be given an upper and lower bound.

The algorithm incorporates the bound constraints by determining the descent direction as in an unconstrained truncated Newton, but never taking a step-size large enough to leave the space of feasible `x`'s. The algorithm keeps track of a set of currently active constraints, and ignores them when computing the minimum allowable step size. (The `x`'s associated with the active constraint are kept fixed.) If the maximum allowable step size is zero then a new constraint is added. At the end of each iteration one of the constraints may be deemed no longer active and removed. A constraint is considered no longer active is if it is currently active but the gradient for that variable points inward from the constraint. The specific constraint removed is the one associated with the variable of largest index whose constraint is no longer active.

Return codes are defined as follows:

```

-1 : Infeasible (lower bound > upper bound)
 0 : Local minimum reached (|pg| ~= 0)
 1 : Converged (|f_n-f_(n-1)| ~= 0)
 2 : Converged (|x_n-x_(n-1)| ~= 0)
 3 : Max. number of function evaluations reached
 4 : Linear search failed
 5 : All lower bounds are equal to the upper bounds
 6 : Unable to progress
 7 : User requested end of minimization
```

**References**

Nash S.G. (1984), “Newton-Type Minimization Via the Lanczos Method”, SIAM Journal of Numerical Analysis 21, pp. 770-778

`scipy.optimize.fmin_cobyla` (*func*, *x0*, *cons*, *args=()*, *consargs=None*, *rhobeg=1.0*, *rhoend=0.0001*, *maxfun=1000*, *disp=None*, *catol=0.0002*)

Minimize a function using the Constrained Optimization BY Linear Approximation (COBYLA) method. This method wraps a FORTRAN implementation of the algorithm.

**Parameters**

**func** : callable

Function to minimize. In the form `func(x, *args)`.

**x0** : ndarray  
Initial guess.

**cons** : sequence  
Constraint functions; must all be  $\geq 0$  (a single function if only 1 constraint). Each function takes the parameters  $x$  as its first argument, and it can return either a single number or an array or list of numbers.

**args** : tuple, optional  
Extra arguments to pass to function.

**consargs** : tuple, optional  
Extra arguments to pass to constraint functions (default of None means use same extra arguments as those passed to func). Use () for no extra arguments.

**rhobeg** : float, optional  
Reasonable initial changes to the variables.

**rhoend** : float, optional  
Final accuracy in the optimization (not precisely guaranteed). This is a lower bound on the size of the trust region.

**disp** : {0, 1, 2, 3}, optional  
Controls the frequency of output; 0 implies no output.

**maxfun** : int, optional  
Maximum number of function evaluations.

**catol** : float, optional  
Absolute tolerance for constraint violations.

**Returns** **x** : ndarray  
The argument that minimises  $f$ .

**See also:**

**minimize** Interface to minimization algorithms for multivariate functions. See the ‘COBYLA’ *method* in particular.

**Notes**

This algorithm is based on linear approximations to the objective function and each constraint. We briefly describe the algorithm.

Suppose the function is being minimized over  $k$  variables. At the  $j$ th iteration the algorithm has  $k+1$  points  $v_1, \dots, v_{k+1}$ , an approximate solution  $x_j$ , and a radius  $RHO_j$ . (i.e. linear plus a constant) approximations to the objective function and constraint functions such that their function values agree with the linear approximation on the  $k+1$  points  $v_1, \dots, v_{k+1}$ . This gives a linear program to solve (where the linear approximations of the constraint functions are constrained to be non-negative).

However the linear approximations are likely only good approximations near the current simplex, so the linear program is given the further requirement that the solution, which will become  $x_{j+1}$ , must be within  $RHO_j$  from  $x_j$ .  $RHO_j$  only decreases, never increases. The initial  $RHO_j$  is `rhobeg` and the final  $RHO_j$  is `rhoend`. In this way COBYLA’s iterations behave like a trust region algorithm.

Additionally, the linear program may be inconsistent, or the approximation may give poor improvement. For details about how these issues are resolved, as well as how the points  $v_i$  are updated, refer to the source code or the references below.

**Examples**

Minimize the objective function  $f(x,y) = x*y$  subject to the constraints  $x**2 + y**2 < 1$  and  $y > 0$ :

```
>>> def objective(x):
...     return x[0]*x[1]
...
>>> def constr1(x):
...     return 1 - (x[0]**2 + x[1]**2)
...
>>> def constr2(x):
...     return x[1]
...
>>> from scipy.optimize import fmin_cobyla
>>> fmin_cobyla(objective, [0.0, 0.1], [constr1, constr2], rhoend=1e-7)
array([-0.70710685,  0.70710671])
```

The exact solution is  $(-\sqrt{2}/2, \sqrt{2}/2)$ .

`scipy.optimize.fmin_slsqp` (*func*, *x0*, *eqcons*=(), *f\_eqcons*=None, *ieqcons*=(), *f\_ieqcons*=None, *bounds*=(), *fprime*=None, *fprime\_eqcons*=None, *fprime\_ieqcons*=None, *args*=(), *iter*=100, *acc*=1e-06, *iprint*=1, *disp*=None, *full\_output*=0, *epsilon*=1.4901161193847656e-08, *callback*=None)

Minimize a function using Sequential Least Squares Programming

Python interface function for the SLSQP Optimization subroutine originally implemented by Dieter Kraft.

- Parameters**
- func** : callable  $f(x,*args)$   
Objective function. Must return a scalar.
  - x0** : 1-D ndarray of float  
Initial guess for the independent variable(s).
  - eqcons** : list, optional  
A list of functions of length  $n$  such that  $eqcons[j](x,*args) == 0.0$  in a successfully optimized problem.
  - f\_eqcons** : callable  $f(x,*args)$ , optional  
Returns a 1-D array in which each element must equal 0.0 in a successfully optimized problem. If *f\_eqcons* is specified, *eqcons* is ignored.
  - ieqcons** : list, optional  
A list of functions of length  $n$  such that  $ieqcons[j](x,*args) >= 0.0$  in a successfully optimized problem.
  - f\_ieqcons** : callable  $f(x,*args)$ , optional  
Returns a 1-D ndarray in which each element must be greater or equal to 0.0 in a successfully optimized problem. If *f\_ieqcons* is specified, *ieqcons* is ignored.
  - bounds** : list, optional  
A list of tuples specifying the lower and upper bound for each independent variable [(x10, xu0),(x11, xu1),...] Infinite values will be interpreted as large floating values.
  - fprime** : callable  $f(x,*args)$ , optional  
A function that evaluates the partial derivatives of *func*.
  - fprime\_eqcons** : callable  $f(x,*args)$ , optional  
A function of the form  $f(x,*args)$  that returns the  $m$  by  $n$  array of equality constraint normals. If not provided, the normals will be approximated. The array returned by *fprime\_eqcons* should be sized as  $(\text{len}(eqcons), \text{len}(x0))$ .
  - fprime\_ieqcons** : callable  $f(x,*args)$ , optional

A function of the form  $f(x, *args)$  that returns the  $m$  by  $n$  array of inequality constraint normals. If not provided, the normals will be approximated. The array returned by `fprime_ieqcons` should be sized as `( len(ieqcons), len(x0) )`.

**args** : sequence, optional

Additional arguments passed to `func` and `fprime`.

**iter** : int, optional

The maximum number of iterations.

**acc** : float, optional

Requested accuracy.

**iprint** : int, optional

The verbosity of `fmin_slsqp` :

- `iprint <= 0` : Silent operation
- `iprint == 1` : Print summary upon completion (default)
- `iprint >= 2` : Print status of each iterate and summary

**disp** : int, optional

Over-rides the `iprint` interface (preferred).

**full\_output** : bool, optional

If False, return only the minimizer of `func` (default). Otherwise, output final objective function and summary information.

**epsilon** : float, optional

The step size for finite-difference derivative estimates.

**callback** : callable, optional

Called after each iteration, as `callback(x)`, where `x` is the current parameter vector.

#### Returns

**out** : ndarray of float

The final minimizer of `func`.

**fx** : ndarray of float, if `full_output` is true

The final value of the objective function.

**its** : int, if `full_output` is true

The number of iterations.

**imode** : int, if `full_output` is true

The exit mode from the optimizer (see below).

**smode** : string, if `full_output` is true

Message describing the exit mode from the optimizer.

#### See also:

**minimize** Interface to minimization algorithms for multivariate functions. See the ‘SLSQP’ *method* in particular.

#### Notes

Exit modes are defined as follows

```
-1 : Gradient evaluation required (g & a)
0 : Optimization terminated successfully.
1 : Function evaluation required (f & c)
2 : More equality constraints than independent variables
3 : More than 3*n iterations in LSQ subproblem
4 : Inequality constraints incompatible
5 : Singular matrix E in LSQ subproblem
6 : Singular matrix C in LSQ subproblem
7 : Rank-deficient equality constraint subproblem HFTI
8 : Positive directional derivative for linesearch
9 : Iteration limit exceeded
```

### Examples

Examples are given *in the tutorial*.

```
scipy.optimize.differential_evolution(func, bounds, args=(), strategy='best1bin', max-  
iter=1000, popsize=15, tol=0.01, mutation=(0.5,  
1), recombination=0.7, seed=None, callback=None,  
disp=False, polish=True, init='latinhypercube',  
atol=0)
```

Finds the global minimum of a multivariate function. Differential Evolution is stochastic in nature (does not use gradient methods) to find the minimum, and can search large areas of candidate space, but often requires larger numbers of function evaluations than conventional gradient based techniques.

The algorithm is due to Storn and Price [R194].

**Parameters** **func** : callable

The objective function to be minimized. Must be in the form  $f(x, *args)$ , where  $x$  is the argument in the form of a 1-D array and  $args$  is a tuple of any additional fixed parameters needed to completely specify the function.

**bounds** : sequence

Bounds for variables.  $(min, max)$  pairs for each element in  $x$ , defining the lower and upper bounds for the optimizing argument of *func*. It is required to have  $len(bounds) == len(x)$ .  $len(bounds)$  is used to determine the number of parameters in  $x$ .

**args** : tuple, optional

Any additional fixed parameters needed to completely specify the objective function.

**strategy** : str, optional

The differential evolution strategy to use. Should be one of:

- 'best1bin'
- 'best1exp'
- 'rand1exp'
- 'randtobest1exp'
- 'best2exp'
- 'rand2exp'
- 'randtobest1bin'
- 'best2bin'
- 'rand2bin'
- 'rand1bin'

The default is 'best1bin'.

**maxiter** : int, optional

The maximum number of generations over which the entire population is evolved. The maximum number of function evaluations (with no polishing) is:  $(maxiter + 1) * popsize * len(x)$

**popsize** : int, optional

A multiplier for setting the total population size. The population has  $popsize * len(x)$  individuals.

**tol** : float, optional

Relative tolerance for convergence, the solving stops when  $np.std(pop) \leq atol + tol * np.abs(np.mean(population_energies))$ , where  $atol$  and  $tol$  are the absolute and relative tolerance respectively.

**mutation** : float or tuple(float, float), optional

The mutation constant. In the literature this is also known as differential weight, being denoted by  $F$ . If specified as a float it should be in the range  $[0, 2]$ . If specified as a tuple  $(min, max)$  dithering is employed. Dithering randomly changes the mutation constant on a generation by generation basis. The mutation constant for that generation is taken from  $U[min, max)$ . Dithering can help speed convergence significantly.

Increasing the mutation constant increases the search radius, but will slow down convergence.

**recombination** : float, optional

The recombination constant, should be in the range [0, 1]. In the literature this is also known as the crossover probability, being denoted by CR. Increasing this value allows a larger number of mutants to progress into the next generation, but at the risk of population stability.

**seed** : int or `np.random.RandomState`, optional

If *seed* is not specified the `np.RandomState` singleton is used. If *seed* is an int, a new `np.random.RandomState` instance is used, seeded with *seed*. If *seed* is already a `np.random.RandomState` instance, then that `np.random.RandomState` instance is used. Specify *seed* for repeatable minimizations.

**disp** : bool, optional

Display status messages

**callback** : callable, `callback(xk, convergence=val)`, optional

A function to follow the progress of the minimization. *xk* is the current value of *x0*. *val* represents the fractional value of the population convergence. When *val* is greater than one the function halts. If callback returns `True`, then the minimization is halted (any polishing is still carried out).

**polish** : bool, optional

If `True` (default), then `scipy.optimize.minimize` with the *L-BFGS-B* method is used to polish the best population member at the end, which can improve the minimization slightly.

**init** : string, optional

Specify how the population initialization is performed. Should be one of:

- 'latinhypercube'
- 'random'

The default is 'latinhypercube'. Latin Hypercube sampling tries to maximize coverage of the available parameter space. 'random' initializes the population randomly - this has the drawback that clustering can occur, preventing the whole of parameter space being covered.

**atol** : float, optional

Absolute tolerance for convergence, the solving stops when `np.std(pop) <= atol + tol * np.abs(np.mean(population_energies))`, where *atol* and *tol* are the absolute and relative tolerance respectively.

### Returns

**res** : `OptimizeResult`

The optimization result represented as a `OptimizeResult` object. Important attributes are: *x* the solution array, *success* a Boolean flag indicating if the optimizer exited successfully and *message* which describes the cause of the termination. See `OptimizeResult` for a description of other attributes. If *polish* was employed, and a lower minimum was obtained by the polishing, then `OptimizeResult` also contains the *jac* attribute.

### Notes

Differential evolution is a stochastic population based method that is useful for global optimization problems. At each pass through the population the algorithm mutates each candidate solution by mixing with other candidate solutions to create a trial candidate. There are several strategies [R195] for creating trial candidates, which suit some problems more than others. The 'best1bin' strategy is a good starting point for many systems. In this strategy two members of the population are randomly chosen. Their difference is used to mutate the best member (the *best* in *best1bin*), *b<sub>0</sub>*, so far:

$$b' = b_0 + \text{mutation} * (\text{population}[\text{rand0}] - \text{population}[\text{rand1}])$$

A trial vector is then constructed. Starting with a randomly chosen 'i'th parameter the trial is sequentially filled (in modulo) with parameters from *b'* or the original candidate. The choice of whether to use *b'* or the original candidate is made with a binomial distribution (the 'bin' in 'best1bin') - a random number in [0, 1) is generated. If this number is less than the *recombination* constant then the parameter is loaded from *b'*, otherwise it is loaded from the original candidate. The final parameter is always loaded from *b'*. Once the trial candidate is built its fitness is assessed. If the trial is better than the original candidate then it takes its place. If it is also better than the best overall candidate it also replaces that. To improve your chances of finding a global minimum use higher *popsize* values, with higher *mutation* and (dithering), but lower *recombination* values. This has the effect of widening the search radius, but slowing convergence.

New in version 0.15.0.

### Examples

Let us consider the problem of minimizing the Rosenbrock function. This function is implemented in *rosen* in *scipy.optimize*.

```
>>> from scipy.optimize import rosen, differential_evolution
>>> bounds = [(0,2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = differential_evolution(rosen, bounds)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 1.9216496320061384e-19)
```

Next find the minimum of the Ackley function ([http://en.wikipedia.org/wiki/Test\\_functions\\_for\\_optimization](http://en.wikipedia.org/wiki/Test_functions_for_optimization)).

```
>>> from scipy.optimize import differential_evolution
>>> import numpy as np
>>> def ackley(x):
...     arg1 = -0.2 * np.sqrt(0.5 * (x[0] ** 2 + x[1] ** 2))
...     arg2 = 0.5 * (np.cos(2. * np.pi * x[0]) + np.cos(2. * np.pi * x[1]))
...     return -20. * np.exp(arg1) - np.exp(arg2) + 20. + np.e
>>> bounds = [(-5, 5), (-5, 5)]
>>> result = differential_evolution(ackley, bounds)
>>> result.x, result.fun
(array([ 0.,  0.]), 4.4408920985006262e-16)
```

Univariate (scalar) minimization methods:

<i>fminbound</i> (func, x1, x2[, args, xtol, ...])	Bounded minimization for scalar functions.
<i>brent</i> (func[, args, brack, tol, full_output, ...])	Given a function of one-variable and a possible bracket, return the local minimum of the function isolated to a fractional precision of tol.
<i>golden</i> (func[, args, brack, tol, ...])	Return the minimum of a function of one variable using golden section method.

`scipy.optimize.fminbound` (*func*, *x1*, *x2*, *args*=(), *xtol*=1e-05, *maxfun*=500, *full\_output*=0, *disp*=1)  
Bounded minimization for scalar functions.

**Parameters**

- func** : callable f(x,\*args)  
Objective function to be minimized (must accept and return scalars).
- x1, x2** : float or array scalar  
The optimization bounds.
- args** : tuple, optional

Extra arguments passed to function.

**xtol** : float, optional  
The convergence tolerance.

**maxfun** : int, optional  
Maximum number of function evaluations allowed.

**full\_output** : bool, optional  
If True, return optional outputs.

**disp** : int, optional  
*If non-zero, print messages.*  
0 : no message printing. 1 : non-convergence notification messages only. 2 : print a message on convergence too. 3 : print iteration results.

**Returns**

**xopt** : ndarray  
Parameters (over given interval) which minimize the objective function.

**fval** : number  
The function value at the minimum point.

**ierr** : int  
An error flag (0 if converged, 1 if maximum number of function calls reached).

**numfunc** : int  
The number of function calls made.

**See also:**

**minimize\_scalar**

Interface to minimization algorithms for scalar univariate functions. See the ‘Bounded’ *method* in particular.

**Notes**

Finds a local minimizer of the scalar function *func* in the interval  $x_1 < x_{opt} < x_2$  using Brent’s method. (See *brent* for auto-bracketing).

**Examples**

*fminbound* finds the minimum of the function in the given range. The following examples illustrate the same

```
>>> def f(x):
...     return x**2
```

```
>>> from scipy import optimize
```

```
>>> minimum = optimize.fminbound(f, -1, 2)
>>> minimum
0.0

```

`scipy.optimize.brent` (*func*, *args*=(), *brack*=None, *tol*=1.48e-08, *full\_output*=0, *maxiter*=500)

Given a function of one-variable and a possible bracket, return the local minimum of the function isolated to a fractional precision of *tol*.

**Parameters**

**func** : callable f(x,\*args)  
Objective function.

**args** : tuple, optional  
Additional arguments (if present).

**brack** : tuple, optional

Either a triple  $(x_a, x_b, x_c)$  where  $x_a < x_b < x_c$  and  $\text{func}(x_b) < \text{func}(x_a)$ ,  $\text{func}(x_c)$  or a pair  $(x_a, x_b)$  which are used as a starting interval for a downhill bracket search (see *bracket*). Providing the pair  $(x_a, x_b)$  does not always mean the obtained solution will satisfy  $x_a \leq x \leq x_b$ .

**tol** : float, optional  
 Stop if between iteration change is less than *tol*.  
**full\_output** : bool, optional  
 If True, return all output args (*xmin*, *fval*, *iter*, *funcalls*).  
**maxiter** : int, optional  
 Maximum number of iterations in solution.

**Returns**

**xmin** : ndarray  
 Optimum point.  
**fval** : float  
 Optimum value.  
**iter** : int  
 Number of iterations.  
**funcalls** : int  
 Number of objective function evaluations made.

**See also:**

**minimize\_scalar**

Interface to minimization algorithms for scalar univariate functions. See the ‘Brent’ *method* in particular.

**Notes**

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method.

Does not ensure that the minimum lies in the range specified by *brack*. See *fminbound*.

**Examples**

We illustrate the behaviour of the function when *brack* is of size 2 and 3 respectively. In the case where *brack* is of the form  $(x_a, x_b)$ , we can see for the given values, the output need not necessarily lie in the range  $(x_a, x_b)$ .

```
>>> def f(x):
...     return x**2
```

```
>>> from scipy import optimize
```

```
>>> minimum = optimize.brent(f, brack=(1, 2))
>>> minimum
0.0
>>> minimum = optimize.brent(f, brack=(-1, 0.5, 2))
>>> minimum
-2.7755575615628914e-17
```

`scipy.optimize.golden` (*func*, *args=()*, *brack=None*, *tol=1.4901161193847656e-08*, *full\_output=0*, *maxiter=5000*)

Return the minimum of a function of one variable using golden section method.

Given a function of one variable and a possible bracketing interval, return the minimum of the function isolated to a fractional precision of *tol*.

**Parameters** **func** : callable `func(x,*args)`  
 Objective function to minimize.  
**args** : tuple, optional

Additional arguments (if present), passed to `func`.

**brack** : tuple, optional

Triple (a,b,c), where (a<b<c) and `func(b) < func(a),func(c)`. If bracket consists of two numbers (a, c), then they are assumed to be a starting interval for a downhill bracket search (see `bracket`); it doesn't always mean that obtained solution will satisfy `a<=x<=c`.

**tol** : float, optional

x tolerance stop criterion

**full\_output** : bool, optional

If True, return optional outputs.

**maxiter** : int

Maximum number of iterations to perform.

See also:

**minimize\_scalar**

Interface to minimization algorithms for scalar univariate functions. See the 'Golden' *method* in particular.

*Notes*

Uses analog of bisection method to decrease the bracketed interval.

*Examples*

We illustrate the behaviour of the function when `brack` is of size 2 and 3 respectively. In the case where `brack` is of the form (xa,xb), we can see for the given values, the output need not necessarily lie in the range (xa, xb).

```
>>> def f(x):
...     return x**2
```

```
>>> from scipy import optimize
```

```
>>> minimum = optimize.golden(f, brack=(1, 2))
>>> minimum
1.5717277788484873e-162
>>> minimum = optimize.golden(f, brack=(-1, 0.5, 2))
>>> minimum
-1.5717277788484873e-162
```

## Equation (Local) Minimizers

<code>leastsq(func, x0[, args, Dfun, full_output, ...])</code>	Minimize the sum of squares of a set of equations.
<code>least_squares(fun, x0[, jac, bounds, ...])</code>	Solve a nonlinear least-squares problem with bounds on the variables.
<code>nnls(A, b)</code>	Solve $\operatorname{argmin}_x   Ax - b  _2$ for $x \geq 0$ .
<code>lsq_linear(A, b[, bounds, method, tol, ...])</code>	Solve a linear least-squares problem with bounds on the variables.

`scipy.optimize.leastsq` (`func, x0, args=()`, `Dfun=None`, `full_output=0`, `col_deriv=0`, `ftol=1.49012e-08`, `xtol=1.49012e-08`, `gtol=0.0`, `maxfev=0`, `epsfcn=None`, `factor=100`, `diag=None`)

Minimize the sum of squares of a set of equations.

```
x = arg min(sum(func(y)**2,axis=0))
           y
```

- Parameters**
- func** : callable  
should take at least one (possibly length N vector) argument and returns M floating point numbers. It must not return NaNs or fitting might fail.
  - x0** : ndarray  
The starting estimate for the minimization.
  - args** : tuple, optional  
Any extra arguments to func are placed in this tuple.
  - Dfun** : callable, optional  
A function or method to compute the Jacobian of func with derivatives across the rows. If this is None, the Jacobian will be estimated.
  - full\_output** : bool, optional  
non-zero to return all optional outputs.
  - col\_deriv** : bool, optional  
non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
  - ftol** : float, optional  
Relative error desired in the sum of squares.
  - xtol** : float, optional  
Relative error desired in the approximate solution.
  - gtol** : float, optional  
Orthogonality desired between the function vector and the columns of the Jacobian.
  - maxfev** : int, optional  
The maximum number of calls to the function. If *Dfun* is provided then the default *maxfev* is 100\*(N+1) where N is the number of elements in x0, otherwise the default *maxfev* is 200\*(N+1).
  - epsfcn** : float, optional  
A variable used in determining a suitable step length for the forward- difference approximation of the Jacobian (for Dfun=None). Normally the actual step length will be sqrt(epsfcn)\*x. If epsfcn is less than the machine precision, it is assumed that the relative errors are of the order of the machine precision.
  - factor** : float, optional  
A parameter determining the initial step bound (`factor * || diag * x||`). Should be in interval (0.1, 100).
  - diag** : sequence, optional  
N positive entries that serve as a scale factors for the variables.
- Returns**
- x** : ndarray  
The solution (or the result of the last iteration for an unsuccessful call).
  - cov\_x** : ndarray  
Uses the *fjac* and *ipvt* optional outputs to construct an estimate of the jacobian around the solution. None if a singular matrix encountered (indicates very flat curvature in some direction). This matrix must be multiplied by the residual variance to get the covariance of the parameter estimates – see `curve_fit`.
  - infodict** : dict  
a dictionary of optional outputs with the key s:
    - nfev**        The number of function calls
    - fvec**        The function evaluated at the output
    - fjac**        A permutation of the R matrix of a QR factorization of the final approximate Jacobian matrix, stored column wise. Together with *ipvt*, the covariance of the estimate can be approximated.

**ipvt** An integer array of length N which defines a permutation matrix, p, such that  $fjac * p = q * r$ , where r is upper triangular with diagonal elements of nonincreasing magnitude. Column j of p is column ipvt(j) of the identity matrix.

**qtf** The vector  $(\text{transpose}(q) * \text{fvec})$ .

**mesg** : str  
A string message giving information about the cause of failure.

**ier** : int  
An integer flag. If it is equal to 1, 2, 3 or 4, the solution was found. Otherwise, the solution was not found. In either case, the optional output variable 'mesg' gives more information.

### Notes

"leastsq" is a wrapper around MINPACK's lmdif and lmdcr algorithms.

cov\_x is a Jacobian approximation to the Hessian of the least squares objective function. This approximation assumes that the objective function is based on the difference between some observed target data (ydata) and a (non-linear) function of the parameters  $f(xdata, params)$

```
func(params) = ydata - f(xdata, params)
```

so that the objective function is

```
min sum((ydata - f(xdata, params))**2, axis=0)
params
```

```
scipy.optimize.least_squares(fun, x0, jac='2-point', bounds=(-inf, inf), method='trf',
                             ftol=1e-08, xtol=1e-08, gtol=1e-08, x_scale=1.0, loss='linear',
                             f_scale=1.0, diff_step=None, tr_solver=None, tr_options={},
                             jac_sparsity=None, max_nfev=None, verbose=0, args=(),
                             kwargs={})
```

Solve a nonlinear least-squares problem with bounds on the variables.

Given the residuals  $f(x)$  (an m-dimensional real function of n real variables) and the loss function  $\rho(s)$  (a scalar function), `least_squares` finds a local minimum of the cost function  $F(x)$ :

```
minimize F(x) = 0.5 * sum(rho(f_i(x)**2), i = 0, ..., m - 1)
subject to lb <= x <= ub
```

The purpose of the loss function  $\rho(s)$  is to reduce the influence of outliers on the solution.

**Parameters** **fun** : callable

Function which computes the vector of residuals, with the signature `fun(x, *args, **kwargs)`, i.e., the minimization proceeds with respect to its first argument. The argument `x` passed to this function is an ndarray of shape (n,) (never a scalar, even for  $n=1$ ). It must return a 1-d array\_like of shape (m,) or a scalar. If the argument `x` is complex or the function `fun` returns complex residuals, it must be wrapped in a real function of real arguments, as shown at the end of the Examples section.

**x0** : array\_like with shape (n,) or float

Initial guess on independent variables. If float, it will be treated as a 1-d array with one element.

**jac** : {'2-point', '3-point', 'cs', callable}, optional

Method of computing the Jacobian matrix (an m-by-n matrix, where element (i, j) is the partial derivative of  $f[i]$  with respect to  $x[j]$ ). The keywords select a finite difference scheme for numerical estimation. The scheme '3-point' is more accurate, but requires twice as much operations compared to '2-point' (default). The scheme 'cs'

uses complex steps, and while potentially the most accurate, it is applicable only when *fun* correctly handles complex inputs and can be analytically continued to the complex plane. Method 'lm' always uses the '2-point' scheme. If callable, it is used as `jac(x, *args, **kwargs)` and should return a good approximation (or the exact value) for the Jacobian as an `array_like` (`np.atleast_2d` is applied), a sparse matrix or a `scipy.sparse.linalg.LinearOperator`.

**bounds** : 2-tuple of `array_like`, optional

Lower and upper bounds on independent variables. Defaults to no bounds. Each array must match the size of `x0` or be a scalar, in the latter case a bound will be the same for all variables. Use `np.inf` with an appropriate sign to disable bounds on all or some variables.

**method** : {'trf', 'dogbox', 'lm'}, optional

Algorithm to perform minimization.

- 'trf' : Trust Region Reflective algorithm, particularly suitable for large sparse problems with bounds. Generally robust method.
- 'dogbox' : dogleg algorithm with rectangular trust regions, typical use case is small problems with bounds. Not recommended for problems with rank-deficient Jacobian.
- 'lm' : Levenberg-Marquardt algorithm as implemented in MINPACK. Doesn't handle bounds and sparse Jacobians. Usually the most efficient method for small unconstrained problems.

Default is 'trf'. See Notes for more information.

**ftol** : float, optional

Tolerance for termination by the change of the cost function. Default is 1e-8. The optimization process is stopped when  $dF < ftol * F$ , and there was an adequate agreement between a local quadratic model and the true model in the last step.

**xtol** : float, optional

Tolerance for termination by the change of the independent variables. Default is 1e-8. The exact condition depends on the *method* used:

- For 'trf' and 'dogbox':  $\text{norm}(dx) < xtol * (xtol + \text{norm}(x))$
- For 'lm':  $\Delta < xtol * \text{norm}(xs)$ , where  $\Delta$  is a trust-region radius and  $xs$  is the value of  $x$  scaled according to `x_scale` parameter (see below).

**gtol** : float, optional

Tolerance for termination by the norm of the gradient. Default is 1e-8. The exact condition depends on a *method* used:

- For 'trf':  $\text{norm}(g\_scaled, \text{ord}=\text{np.inf}) < gtol$ , where `g_scaled` is the value of the gradient scaled to account for the presence of the bounds [STIR].
- For 'dogbox':  $\text{norm}(g\_free, \text{ord}=\text{np.inf}) < gtol$ , where `g_free` is the gradient with respect to the variables which are not in the optimal state on the boundary.
- For 'lm': the maximum absolute value of the cosine of angles between columns of the Jacobian and the residual vector is less than `gtol`, or the residual vector is zero.

**x\_scale** : `array_like` or 'jac', optional

Characteristic scale of each variable. Setting `x_scale` is equivalent to reformulating the problem in scaled variables  $xs = x / x\_scale$ . An alternative view is that the size of a trust region along *j*-th dimension is proportional to `x_scale[j]`. Improved convergence may be achieved by setting `x_scale` such that a step of a given size along any of the scaled variables has a similar effect on the cost function. If set to 'jac', the scale is iteratively updated using the inverse norms of the columns of the Jacobian matrix (as described in [JJMore]).

**loss** : str or callable, optional

Determines the loss function. The following keyword values are allowed:

- 'linear' (default):  $\rho(z) = z$ . Gives a standard least-squares problem.

- ‘soft\_l1’:  $\rho(z) = 2 * ((1 + z)**0.5 - 1)$ . The smooth approximation of l1 (absolute value) loss. Usually a good choice for robust least squares.
- ‘huber’:  $\rho(z) = z$  if  $z \leq 1$  else  $2*z**0.5 - 1$ . Works similarly to ‘soft\_l1’.
- ‘cauchy’:  $\rho(z) = \ln(1 + z)$ . Severely weakens outliers influence, but may cause difficulties in optimization process.
- ‘arctan’:  $\rho(z) = \arctan(z)$ . Limits a maximum loss on a single residual, has properties similar to ‘cauchy’.

If callable, it must take a 1-d ndarray  $z=f**2$  and return an array\_like with shape (3, m) where row 0 contains function values, row 1 contains first derivatives and row 2 contains second derivatives. Method ‘lm’ supports only ‘linear’ loss.

**f\_scale** : float, optional

Value of soft margin between inlier and outlier residuals, default is 1.0. The loss function is evaluated as follows  $\rho_-(f**2) = C**2 * \rho(f**2 / C**2)$ , where C is *f\_scale*, and  $\rho$  is determined by *loss* parameter. This parameter has no effect with *loss*='linear', but for other *loss* values it is of crucial importance.

**max\_nfev** : None or int, optional

Maximum number of function evaluations before the termination. If None (default), the value is chosen automatically:

- For ‘trf’ and ‘dogbox’:  $100 * n$ .
- For ‘lm’:  $100 * n$  if *jac* is callable and  $100 * n * (n + 1)$  otherwise (because ‘lm’ counts function calls in Jacobian estimation).

**diff\_step** : None or array\_like, optional

Determines the relative step size for the finite difference approximation of the Jacobian. The actual step is computed as  $x * \text{diff\_step}$ . If None (default), then *diff\_step* is taken to be a conventional “optimal” power of machine epsilon for the finite difference scheme used [NR].

**tr\_solver** : {None, ‘exact’, ‘lsmr’}, optional

Method for solving trust-region subproblems, relevant only for ‘trf’ and ‘dogbox’ methods.

- ‘exact’ is suitable for not very large problems with dense Jacobian matrices. The computational complexity per iteration is comparable to a singular value decomposition of the Jacobian matrix.
- ‘lsmr’ is suitable for problems with sparse and large Jacobian matrices. It uses the iterative procedure `scipy.sparse.linalg.lsmr` for finding a solution of a linear least-squares problem and only requires matrix-vector product evaluations.

If None (default) the solver is chosen based on the type of Jacobian returned on the first iteration.

**tr\_options** : dict, optional

Keyword options passed to trust-region solver.

- tr\_solver*='exact': *tr\_options* are ignored.
- tr\_solver*='lsmr': options for `scipy.sparse.linalg.lsmr`. Additionally *method*='trf' supports ‘regularize’ option (bool, default is True) which adds a regularization term to the normal equation, which improves convergence if the Jacobian is rank-deficient [Byrd] (eq. 3.4).

**jac\_sparsity** : {None, array\_like, sparse matrix}, optional

Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape must be (m, n). If the Jacobian has only few non-zero elements in *each* row, providing the sparsity structure will greatly speed up the computations [Curtis]. A zero entry means that a corresponding element in the Jacobian is identically zero. If provided, forces the use of ‘lsmr’ trust-region solver. If None (default) then dense differencing will be used. Has no effect for ‘lm’ method.

**verbose** : {0, 1, 2}, optional

Level of algorithm’s verbosity:

- 0 (default) : work silently.
- 1 : display a termination report.
- 2 : display progress during iterations (not supported by ‘lm’ method).

**args, kwargs** : tuple and dict, optional

Additional arguments passed to *fun* and *jac*. Both empty by default. The calling signature is *fun*(*x*, \**args*, \*\**kwargs*) and the same for *jac*.

**Returns** *OptimizeResult* with the following fields defined:

**x** : ndarray, shape (n,)

Solution found.

**cost** : float

Value of the cost function at the solution.

**fun** : ndarray, shape (m,)

Vector of residuals at the solution.

**jac** : ndarray, sparse matrix or LinearOperator, shape (m, n)

Modified Jacobian matrix at the solution, in the sense that  $J^T J$  is a Gauss-Newton approximation of the Hessian of the cost function. The type is the same as the one used by the algorithm.

**grad** : ndarray, shape (m,)

Gradient of the cost function at the solution.

**optimality** : float

First-order optimality measure. In unconstrained problems, it is always the uniform norm of the gradient. In constrained problems, it is the quantity which was compared with *gtol* during iterations.

**active\_mask** : ndarray of int, shape (n,)

Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):

- 0 : a constraint is not active.
- 1 : a lower bound is active.
- 1 : an upper bound is active.

Might be somewhat arbitrary for ‘trf’ method as it generates a sequence of strictly feasible iterates and *active\_mask* is determined within a tolerance threshold.

**nfev** : int

Number of function evaluations done. Methods ‘trf’ and ‘dogbox’ do not count function calls for numerical Jacobian approximation, as opposed to ‘lm’ method.

**njev** : int or None

Number of Jacobian evaluations done. If numerical Jacobian approximation is used in ‘lm’ method, it is set to None.

**status** : int

The reason for algorithm termination:

- 1 : improper input parameters status returned from MINPACK.
- 0 : the maximum number of function evaluations is exceeded.
- 1 : *gtol* termination condition is satisfied.
- 2 : *ftol* termination condition is satisfied.
- 3 : *xtol* termination condition is satisfied.
- 4 : Both *ftol* and *xtol* termination conditions are satisfied.

**message** : str

Verbal description of the termination reason.

**success** : bool

True if one of the convergence criteria is satisfied (*status* > 0).

See also:

**leastsq** A legacy wrapper for the MINPACK implementation of the Levenberg-Marquadt algorithm.

**curve\_fit** Least-squares minimization applied to a curve fitting problem.

### Notes

Method ‘lm’ (Levenberg-Marquardt) calls a wrapper over least-squares algorithms implemented in MINPACK (lmdcr, lmdif). It runs the Levenberg-Marquardt algorithm formulated as a trust-region type algorithm. The implementation is based on paper [JJMore], it is very robust and efficient with a lot of smart tricks. It should be your first choice for unconstrained problems. Note that it doesn’t support bounds. Also it doesn’t work when  $m < n$ .

Method ‘trf’ (Trust Region Reflective) is motivated by the process of solving a system of equations, which constitute the first-order optimality condition for a bound-constrained minimization problem as formulated in [STIR]. The algorithm iteratively solves trust-region subproblems augmented by a special diagonal quadratic term and with trust-region shape determined by the distance from the bounds and the direction of the gradient. This enhancements help to avoid making steps directly into bounds and efficiently explore the whole space of variables. To further improve convergence, the algorithm considers search directions reflected from the bounds. To obey theoretical requirements, the algorithm keeps iterates strictly feasible. With dense Jacobians trust-region subproblems are solved by an exact method very similar to the one described in [JJMore] (and implemented in MINPACK). The difference from the MINPACK implementation is that a singular value decomposition of a Jacobian matrix is done once per iteration, instead of a QR decomposition and series of Givens rotation eliminations. For large sparse Jacobians a 2-d subspace approach of solving trust-region subproblems is used [STIR], [Byrd]. The subspace is spanned by a scaled gradient and an approximate Gauss-Newton solution delivered by `scipy.sparse.linalg.lsmr`. When no constraints are imposed the algorithm is very similar to MINPACK and has generally comparable performance. The algorithm works quite robust in unbounded and bounded problems, thus it is chosen as a default algorithm.

Method ‘dogbox’ operates in a trust-region framework, but considers rectangular trust regions as opposed to conventional ellipsoids [Voglis]. The intersection of a current trust region and initial bounds is again rectangular, so on each iteration a quadratic minimization problem subject to bound constraints is solved approximately by Powell’s dogleg method [NumOpt]. The required Gauss-Newton step can be computed exactly for dense Jacobians or approximately by `scipy.sparse.linalg.lsmr` for large sparse Jacobians. The algorithm is likely to exhibit slow convergence when the rank of Jacobian is less than the number of variables. The algorithm often outperforms ‘trf’ in bounded problems with a small number of variables.

Robust loss functions are implemented as described in [BA]. The idea is to modify a residual vector and a Jacobian matrix on each iteration such that computed gradient and Gauss-Newton Hessian approximation match the true gradient and Hessian approximation of the cost function. Then the algorithm proceeds in a normal way, i.e. robust loss functions are implemented as a simple wrapper over standard least-squares algorithms.

New in version 0.17.0.

### Examples

In this example we find a minimum of the Rosenbrock function without bounds on independent variables.

```
>>> def fun_rosenbrock(x):
...     return np.array([10 * (x[1] - x[0]**2), (1 - x[0])])
```

Notice that we only provide the vector of the residuals. The algorithm constructs the cost function as a sum of squares of the residuals, which gives the Rosenbrock function. The exact minimum is at  $x = [1.0, 1.0]$ .

```
>>> from scipy.optimize import least_squares
>>> x0_rosenbrock = np.array([2, 2])
>>> res_1 = least_squares(fun_rosenbrock, x0_rosenbrock)
>>> res_1.x
array([ 1.,  1.]
```

```
>>> res_1.cost
9.8669242910846867e-30
>>> res_1.optimality
8.8928864934219529e-14
```

We now constrain the variables, in such a way that the previous solution becomes infeasible. Specifically, we require that  $x[1] \geq 1.5$ , and  $x[0]$  left unconstrained. To this end, we specify the *bounds* parameter to *least\_squares* in the form `bounds=(-np.inf, 1.5], np.inf)`.

We also provide the analytic Jacobian:

```
>>> def jac_rosenbrock(x):
...     return np.array([
...         [-20 * x[0], 10],
...         [-1, 0]])
```

Putting this all together, we see that the new solution lies on the bound:

```
>>> res_2 = least_squares(fun_rosenbrock, x0_rosenbrock, jac_rosenbrock,
...                       bounds=(-np.inf, 1.5], np.inf))
>>> res_2.x
array([ 1.22437075,  1.5          ])
>>> res_2.cost
0.025213093946805685
>>> res_2.optimality
1.5885401433157753e-07
```

Now we solve a system of equations (i.e., the cost function should be zero at a minimum) for a Broyden tridiagonal vector-valued function of 100000 variables:

```
>>> def fun_broyden(x):
...     f = (3 - x) * x + 1
...     f[1:] -= x[:-1]
...     f[:-1] -= 2 * x[1:]
...     return f
```

The corresponding Jacobian matrix is sparse. We tell the algorithm to estimate it by finite differences and provide the sparsity structure of Jacobian to significantly speed up this process.

```
>>> from scipy.sparse import lil_matrix
>>> def sparsity_broyden(n):
...     sparsity = lil_matrix((n, n), dtype=int)
...     i = np.arange(n)
...     sparsity[i, i] = 1
...     i = np.arange(1, n)
...     sparsity[i, i - 1] = 1
...     i = np.arange(n - 1)
...     sparsity[i, i + 1] = 1
...     return sparsity
...
>>> n = 100000
>>> x0_broyden = -np.ones(n)
...
>>> res_3 = least_squares(fun_broyden, x0_broyden,
...                       jac_sparsity=sparsity_broyden(n))
>>> res_3.cost
4.5687069299604613e-23
```

```
>>> res_3.optimality
1.1650454296851518e-11
```

Let's also solve a curve fitting problem using robust loss function to take care of outliers in the data. Define the model function as  $y = a + b * \exp(c * t)$ , where  $t$  is a predictor variable,  $y$  is an observation and  $a$ ,  $b$ ,  $c$  are parameters to estimate.

First, define the function which generates the data with noise and outliers, define the model parameters, and generate data:

```
>>> def gen_data(t, a, b, c, noise=0, n_outliers=0, random_state=0):
...     y = a + b * np.exp(t * c)
...
...     rnd = np.random.RandomState(random_state)
...     error = noise * rnd.randn(t.size)
...     outliers = rnd.randint(0, t.size, n_outliers)
...     error[outliers] *= 10
...
...     return y + error
...
>>> a = 0.5
>>> b = 2.0
>>> c = -1
>>> t_min = 0
>>> t_max = 10
>>> n_points = 15
...
>>> t_train = np.linspace(t_min, t_max, n_points)
>>> y_train = gen_data(t_train, a, b, c, noise=0.1, n_outliers=3)
```

Define function for computing residuals and initial estimate of parameters.

```
>>> def fun(x, t, y):
...     return x[0] + x[1] * np.exp(x[2] * t) - y
...
>>> x0 = np.array([1.0, 1.0, 0.0])
```

Compute a standard least-squares solution:

```
>>> res_lsq = least_squares(fun, x0, args=(t_train, y_train))
```

Now compute two solutions with two different robust loss functions. The parameter *f\_scale* is set to 0.1, meaning that inlier residuals should not significantly exceed 0.1 (the noise level used).

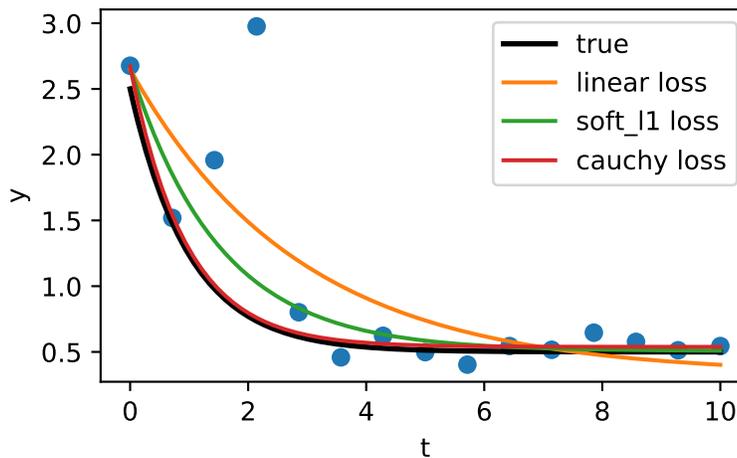

```
>>> res_soft_l1 = least_squares(fun, x0, loss='soft_l1', f_scale=0.1,
...                             args=(t_train, y_train))
>>> res_log = least_squares(fun, x0, loss='cauchy', f_scale=0.1,
...                          args=(t_train, y_train))
```

And finally plot all the curves. We see that by selecting an appropriate *loss* we can get estimates close to optimal even in the presence of strong outliers. But keep in mind that generally it is recommended to try 'soft\_l1' or 'huber' losses first (if at all necessary) as the other two options may cause difficulties in optimization process.

```
>>> t_test = np.linspace(t_min, t_max, n_points * 10)
>>> y_true = gen_data(t_test, a, b, c)
>>> y_lsq = gen_data(t_test, *res_lsq.x)
>>> y_soft_l1 = gen_data(t_test, *res_soft_l1.x)
>>> y_log = gen_data(t_test, *res_log.x)
```

```

...
>>> import matplotlib.pyplot as plt
>>> plt.plot(t_train, y_train, 'o')
>>> plt.plot(t_test, y_true, 'k', linewidth=2, label='true')
>>> plt.plot(t_test, y_lsq, label='linear loss')
>>> plt.plot(t_test, y_soft_l1, label='soft_l1 loss')
>>> plt.plot(t_test, y_log, label='cauchy loss')
>>> plt.xlabel("t")
>>> plt.ylabel("y")
>>> plt.legend()
>>> plt.show()
    
```

In the next example, we show how complex-valued residual functions of complex variables can be optimized with `least_squares()`. Consider the following function:

```

>>> def f(z):
...     return z - (0.5 + 0.5j)
    
```

We wrap it into a function of real variables that returns real residuals by simply handling the real and imaginary parts as independent variables:

```

>>> def f_wrap(x):
...     fx = f(x[0] + 1j*x[1])
...     return np.array([fx.real, fx.imag])
    
```

Thus, instead of the original  $m$ -dimensional complex function of  $n$  complex variables we optimize a  $2m$ -dimensional real function of  $2n$  real variables:

```

>>> from scipy.optimize import least_squares
>>> res_wrapped = least_squares(f_wrap, (0.1, 0.1), bounds=([0, 0], [1, 1]))
>>> z = res_wrapped.x[0] + res_wrapped.x[1]*1j
>>> z
(0.49999999999925893+0.49999999999925893j)
    
```

`scipy.optimize.nnls(A, b)`

Solve  $\operatorname{argmin}_x ||Ax - b||_2$  for  $x \geq 0$ . This is a wrapper for a FORTRAN non-negative least squares solver.

**Parameters** **A** : ndarray  
Matrix **A** as shown above.

**b** : ndarray  
Right-hand side vector.

**Returns** **x** : ndarray  
Solution vector.

**rnorm** : float  
The residual,  $\|Ax - b\|_2$ .

**Notes**

The FORTRAN code was published in the book below. The algorithm is an active set method. It solves the KKT (Karush-Kuhn-Tucker) conditions for the non-negative least squares problem.

**References**

Lawson C., Hanson R.J., (1987) Solving Least Squares Problems, SIAM

`scipy.optimize.lsq_linear` (*A*, *b*, *bounds*=(-inf, inf), *method*='trf', *tol*=1e-10, *lsq\_solver*=None, *lsnr\_tol*=None, *max\_iter*=None, *verbose*=0)

Solve a linear least-squares problem with bounds on the variables.

Given a *m*-by-*n* design matrix *A* and a target vector *b* with *m* elements, *lsq\_linear* solves the following optimization problem:

```
minimize 0.5 * ||A x - b||**2
subject to lb <= x <= ub
```

This optimization problem is convex, hence a found minimum (if iterations have converged) is guaranteed to be global.

**Parameters** **A** : array\_like, sparse matrix of LinearOperator, shape (*m*, *n*)  
Design matrix. Can be `scipy.sparse.linalg.LinearOperator`.

**b** : array\_like, shape (*m*,)  
Target vector.

**bounds** : 2-tuple of array\_like, optional  
Lower and upper bounds on independent variables. Defaults to no bounds. Each array must have shape (*n*,) or be a scalar, in the latter case a bound will be the same for all variables. Use `np.inf` with an appropriate sign to disable bounds on all or some variables.

**method** : 'trf' or 'bvls', optional  
Method to perform minimization.

- 'trf' : Trust Region Reflective algorithm adapted for a linear least-squares problem. This is an interior-point-like method and the required number of iterations is weakly correlated with the number of variables.
- 'bvls' : Bounded-Variable Least-Squares algorithm. This is an active set method, which requires the number of iterations comparable to the number of variables. Can't be used when *A* is sparse or LinearOperator.

Default is 'trf'.

**tol** : float, optional  
Tolerance parameter. The algorithm terminates if a relative change of the cost function is less than *tol* on the last iteration. Additionally the first-order optimality measure is considered:

- `method='trf'` terminates if the uniform norm of the gradient, scaled to account for the presence of the bounds, is less than *tol*.
- `method='bvls'` terminates if Karush-Kuhn-Tucker conditions are satisfied within *tol* tolerance.

**lsq\_solver** : {None, 'exact', 'lsmr'}, optional  
 Method of solving unbounded least-squares problems throughout iterations:

- 'exact' : Use dense QR or SVD decomposition approach. Can't be used when *A* is sparse or `LinearOperator`.
- 'lsmr' : Use `scipy.sparse.linalg.lsmr` iterative procedure which requires only matrix-vector product evaluations. Can't be used with `method='bvls'`.

If None (default) the solver is chosen based on type of *A*.

**lsmr\_tol** : None, float or 'auto', optional  
 Tolerance parameters 'atol' and 'btol' for `scipy.sparse.linalg.lsmr` If None (default), it is set to  $1e-2 * tol$ . If 'auto', the tolerance will be adjusted based on the optimality of the current iterate, which can speed up the optimization process, but is not always reliable.

**max\_iter** : None or int, optional  
 Maximum number of iterations before termination. If None (default), it is set to 100 for `method='trf'` or to the number of variables for `method='bvls'` (not counting iterations for 'bvls' initialization).

**verbose** : {0, 1, 2}, optional  
 Level of algorithm's verbosity:

- 0 : work silently (default).
- 1 : display a termination report.
- 2 : display progress during iterations.

**Returns** `OptimizeResult` with the following fields defined:

**x** : ndarray, shape (n,)
   
Solution found.

**cost** : float
   
Value of the cost function at the solution.

**fun** : ndarray, shape (m,)
   
Vector of residuals at the solution.

**optimality** : float
   
First-order optimality measure. The exact meaning depends on *method*, refer to the description of *tol* parameter.

**active\_mask** : ndarray of int, shape (n,)
   
Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):

- 0 : a constraint is not active.
- -1 : a lower bound is active.
- 1 : an upper bound is active.

Might be somewhat arbitrary for the *trf* method as it generates a sequence of strictly feasible iterates and `active_mask` is determined within a tolerance threshold.

**nit** : int
   
Number of iterations. Zero if the unconstrained solution is optimal.

**status** : int
   
Reason for algorithm termination:

- -1 : the algorithm was not able to make progress on the last iteration.
- 0 : the maximum number of iterations is exceeded.
- 1 : the first-order optimality measure is less than *tol*.
- 2 : the relative change of the cost function is less than *tol*.
- 3 : the unconstrained solution is optimal.

**message** : str
   
Verbal description of the termination reason.

**success** : bool
   
True if one of the convergence criteria is satisfied (*status* > 0).

See also:

**nnls** Linear least squares with non-negativity constraint.

**least\_squares**  
Nonlinear least squares with bounds on the variables.

### Notes

The algorithm first computes the unconstrained least-squares solution by `numpy.linalg.lstsq` or `scipy.sparse.linalg.lsmr` depending on `lsq_solver`. This solution is returned as optimal if it lies within the bounds.

Method 'trf' runs the adaptation of the algorithm described in [STIR] for a linear least-squares problem. The iterations are essentially the same as in the nonlinear least-squares algorithm, but as the quadratic function model is always accurate, we don't need to track or modify the radius of a trust region. The line search (backtracking) is used as a safety net when a selected step does not decrease the cost function. Read more detailed description of the algorithm in `scipy.optimize.least_squares`.

Method 'bvls' runs a Python implementation of the algorithm described in [BVLS]. The algorithm maintains active and free sets of variables, on each iteration chooses a new variable to move from the active set to the free set and then solves the unconstrained least-squares problem on free variables. This algorithm is guaranteed to give an accurate solution eventually, but may require up to  $n$  iterations for a problem with  $n$  variables. Additionally, an ad-hoc initialization procedure is implemented, that determines which variables to set free or active initially. It takes some number of iterations before actual BVLS starts, but can significantly reduce the number of further iterations.

### Examples

In this example a problem with a large sparse matrix and bounds on the variables is solved.

```
>>> from scipy.sparse import rand
>>> from scipy.optimize import lsq_linear
...
>>> np.random.seed(0)
...
>>> m = 20000
>>> n = 10000
...
>>> A = rand(m, n, density=1e-4)
>>> b = np.random.randn(m)
...
>>> lb = np.random.randn(n)
>>> ub = lb + 1
...
>>> res = lsq_linear(A, b, bounds=(lb, ub), lsmr_tol='auto', verbose=1)
# may vary
The relative change of the cost function is less than `tol`.
Number of iterations 16, initial cost 1.5039e+04, final cost 1.1112e+04,
first-order optimality 4.66e-08.
```

## Global Optimization

<code>basinhopping(func, x0[, niter, T, stepsize, ...])</code>	Find the global minimum of a function using the basin-hopping algorithm
<code>brute(func, ranges[, args, Ns, full_output, ...])</code>	Minimize a function over a given range by brute force.
<code>differential_evolution(func, bounds[, args, ...])</code>	Finds the global minimum of a multivariate function.

`scipy.optimize.basinhopping` (*func*, *x0*, *niter*=100, *T*=1.0, *stepsize*=0.5, *minimizer\_kwargs*=None, *take\_step*=None, *accept\_test*=None, *callback*=None, *interval*=50, *disp*=False, *niter\_success*=None, *seed*=None)

Find the global minimum of a function using the basin-hopping algorithm

**Parameters**

- func** : callable `f(x, *args)`  
Function to be optimized. `args` can be passed as an optional item in the dict `minimizer_kwargs`
- x0** : ndarray  
Initial guess.
- niter** : integer, optional  
The number of basin hopping iterations
- T** : float, optional  
The “temperature” parameter for the accept or reject criterion. Higher “temperatures” mean that larger jumps in function value will be accepted. For best results `T` should be comparable to the separation (in function value) between local minima.
- stepsize** : float, optional  
initial step size for use in the random displacement.
- minimizer\_kwargs** : dict, optional  
Extra keyword arguments to be passed to the minimizer `scipy.optimize.minimize()` Some important options could be:
  - method** [str] The minimization method (e.g. "L-BFGS-B")
  - args** [tuple] Extra arguments passed to the objective function (`func`) and its derivatives (Jacobian, Hessian).
- take\_step** : callable `take_step(x)`, optional  
Replace the default step taking routine with this routine. The default step taking routine is a random displacement of the coordinates, but other step taking algorithms may be better for some systems. `take_step` can optionally have the attribute `take_step.stepsize`. If this attribute exists, then `basinhopping` will adjust `take_step.stepsize` in order to try to optimize the global minimum search.
- accept\_test** : callable, `accept_test(f_new=f_new, x_new=x_new, f_old=fold, x_old=x_old)`, optional  
Define a test which will be used to judge whether or not to accept the step. This will be used in addition to the Metropolis test based on “temperature” `T`. The acceptable return values are `True`, `False`, or "force accept". If any of the tests return `False` then the step is rejected. If the latter, then this will override any other tests in order to accept the step. This can be used, for example, to forcefully escape from a local minimum that `basinhopping` is trapped in.
- callback** : callable, `callback(x, f, accept)`, optional  
A callback function which will be called for all minima found. `x` and `f` are the coordinates and function value of the trial minimum, and `accept` is whether or not that minimum was accepted. This can be used, for example, to save the lowest `N` minima found. Also, `callback` can be used to specify a user defined stop criterion by optionally returning `True` to stop the `basinhopping` routine.
- interval** : integer, optional  
interval for how often to update the `stepsize`
- disp** : bool, optional  
Set to `True` to print status messages

**niter\_success** : integer, optional

Stop the run if the global minimum candidate remains the same for this number of iterations.

**seed** : int or *np.random.RandomState*, optional

If *seed* is not specified the *np.RandomState* singleton is used. If *seed* is an int, a new *np.random.RandomState* instance is used, seeded with *seed*. If *seed* is already a *np.random.RandomState* instance, then that *np.random.RandomState* instance is used. Specify *seed* for repeatable minimizations. The random numbers generated with this seed only affect the default Metropolis *accept\_test* and the default *take\_step*. If you supply your own *take\_step* and *accept\_test*, and these functions use random number generation, then those functions are responsible for the state of their random number generator.

**Returns** **res** : *OptimizeResult*

The optimization result represented as a *OptimizeResult* object. Important attributes are: *x* the solution array, *fun* the value of the function at the solution, and *message* which describes the cause of the termination. The *OptimizeResult* object returned by the selected minimizer at the lowest minimum is also contained within this object and can be accessed through the *lowest\_optimization\_result* attribute. See *OptimizeResult* for a description of other attributes.

**See also:**

**minimize** The local minimization function called once for each basin-hopping step. *minimizer\_kwargs* is passed to this routine.

**Notes**

Basin-hopping is a stochastic algorithm which attempts to find the global minimum of a smooth scalar function of one or more variables [R188] [R189] [R190] [R191]. The algorithm in its current form was described by David Wales and Jonathan Doye [R189] <http://www-wales.ch.cam.ac.uk/>.

The algorithm is iterative with each cycle composed of the following features

- 1.random perturbation of the coordinates
- 2.local minimization
- 3.accept or reject the new coordinates based on the minimized function value

The acceptance test used here is the Metropolis criterion of standard Monte Carlo algorithms, although there are many other possibilities [R190].

This global minimization method has been shown to be extremely efficient for a wide variety of problems in physics and chemistry. It is particularly useful when the function has many minima separated by large barriers. See the Cambridge Cluster Database <http://www-wales.ch.cam.ac.uk/CCD.html> for databases of molecular systems that have been optimized primarily using basin-hopping. This database includes minimization problems exceeding 300 degrees of freedom.

See the free software program GMIN (<http://www-wales.ch.cam.ac.uk/GMIN>) for a Fortran implementation of basin-hopping. This implementation has many different variations of the procedure described above, including more advanced step taking algorithms and alternate acceptance criterion.

For stochastic global optimization there is no way to determine if the true global minimum has actually been found. Instead, as a consistency check, the algorithm can be run from a number of different random starting points to ensure the lowest minimum found in each example has converged to the global minimum. For this reason *basinhopping* will by default simply run for the number of iterations *niter* and return the lowest minimum found. It is left to the user to ensure that this is in fact the global minimum.

Choosing `stepsize`: This is a crucial parameter in `basinhopping` and depends on the problem being solved. Ideally it should be comparable to the typical separation between local minima of the function being optimized. `basinhopping` will, by default, adjust `stepsize` to find an optimal value, but this may take many iterations. You will get quicker results if you set a sensible value for `stepsize`.

Choosing `T`: The parameter `T` is the temperature used in the metropolis criterion. Basinhopping steps are accepted with probability 1 if `func(xnew) < func(xold)`, or otherwise with probability:

$$\exp(-(\text{func}(\text{xnew}) - \text{func}(\text{xold})) / T)$$

So, for best results, `T` should be comparable to the typical difference in function values between local minima. New in version 0.12.0.

### References

[R188], [R189], [R190], [R191]

### Examples

The following example is a one-dimensional minimization problem, with many local minima superimposed on a parabola.

```
>>> from scipy.optimize import basinhopping
>>> func = lambda x: np.cos(14.5 * x - 0.3) + (x + 0.2) * x
>>> x0=[1.]
```

`Basinhopping`, internally, uses a local minimization algorithm. We will use the parameter `minimizer_kwargs` to tell `basinhopping` which algorithm to use and how to set up that minimizer. This parameter will be passed to `scipy.optimize.minimize()`.

```
>>> minimizer_kwargs = {"method": "BFGS"}
>>> ret = basinhopping(func, x0, minimizer_kwargs=minimizer_kwargs,
...                   niter=200)
>>> print("global minimum: x = %.4f, f(x0) = %.4f" % (ret.x, ret.fun))
global minimum: x = -0.1951, f(x0) = -1.0009
```

Next consider a two-dimensional minimization problem. Also, this time we will use gradient information to significantly speed up the search.

```
>>> def func2d(x):
...     f = np.cos(14.5 * x[0] - 0.3) + (x[1] + 0.2) * x[1] + (x[0] +
...                                                         0.2) * x[0]
...     df = np.zeros(2)
...     df[0] = -14.5 * np.sin(14.5 * x[0] - 0.3) + 2. * x[0] + 0.2
...     df[1] = 2. * x[1] + 0.2
...     return f, df
```

We'll also use a different local minimization algorithm. Also we must tell the minimizer that our function returns both energy and gradient (jacobian)

```
>>> minimizer_kwargs = {"method": "L-BFGS-B", "jac": True}
>>> x0 = [1.0, 1.0]
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                   niter=200)
>>> print("global minimum: x = [%.4f, %.4f], f(x0) = %.4f" % (ret.x[0],
...                                                         ret.x[1],
...                                                         ret.fun))
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```

Here is an example using a custom step taking routine. Imagine you want the first coordinate to take larger steps than the rest of the coordinates. This can be implemented like so:

```
>>> class MyTakeStep(object):
...     def __init__(self, stepsize=0.5):
...         self.stepsize = stepsize
...     def __call__(self, x):
...         s = self.stepsize
...         x[0] += np.random.uniform(-2.*s, 2.*s)
...         x[1:] += np.random.uniform(-s, s, x[1:].shape)
...         return x
```

Since `MyTakeStep.stepsize` exists `basinhopping` will adjust the magnitude of `stepsize` to optimize the search. We'll use the same 2-D function as before

```
>>> mytakestep = MyTakeStep()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                   niter=200, take_step=mytakestep)
>>> print("global minimum: x = [%.4f, %.4f], f(x0) = %.4f" % (ret.x[0],
...                                                         ret.x[1],
...                                                         ret.fun))
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```

Now let's do an example using a custom callback function which prints the value of every minimum found

```
>>> def print_fun(x, f, accepted):
...     print("at minimum %.4f accepted %d" % (f, int(accepted)))
```

We'll run it for only 10 `basinhopping` steps this time.

```
>>> np.random.seed(1)
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                   niter=10, callback=print_fun)
at minimum 0.4159 accepted 1
at minimum -0.9073 accepted 1
at minimum -0.1021 accepted 1
at minimum -0.1021 accepted 1
at minimum 0.9102 accepted 1
at minimum 0.9102 accepted 1
at minimum 2.2945 accepted 0
at minimum -0.1021 accepted 1
at minimum -1.0109 accepted 1
at minimum -1.0109 accepted 1
```

The minimum at `-1.0109` is actually the global minimum, found already on the 8th iteration.

Now let's implement bounds on the problem using a custom `accept_test`:

```
>>> class MyBounds(object):
...     def __init__(self, xmax=[1.1,1.1], xmin=[-1.1,-1.1]):
...         self.xmax = np.array(xmax)
...         self.xmin = np.array(xmin)
...     def __call__(self, **kwargs):
...         x = kwargs["x_new"]
...         tmax = bool(np.all(x <= self.xmax))
...         tmin = bool(np.all(x >= self.xmin))
...         return tmax and tmin
```

```
>>> mybounds = MyBounds()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                   niter=10, accept_test=mybounds)
```

`scipy.optimize.brute` (*func*, *ranges*, *args=()*, *Ns=20*, *full\_output=0*, *finish=<function fmin>*, *disp=False*)

Minimize a function over a given range by brute force.

Uses the “brute force” method, i.e. computes the function’s value at each point of a multidimensional grid of points, to find the global minimum of the function.

The function is evaluated everywhere in the range with the datatype of the first call to the function, as enforced by the `vectorize` NumPy function. The value and type of the function evaluation returned when `full_output=True` are affected in addition by the `finish` argument (see Notes).

**Parameters** **func** : callable

The objective function to be minimized. Must be in the form `f(x, *args)`, where `x` is the argument in the form of a 1-D array and `args` is a tuple of any additional fixed parameters needed to completely specify the function.

**ranges** : tuple

Each component of the `ranges` tuple must be either a “slice object” or a range tuple of the form `(low, high)`. The program uses these to create the grid of points on which the objective function will be computed. See *Note 2* for more detail.

**args** : tuple, optional

Any additional fixed parameters needed to completely specify the function.

**Ns** : int, optional

Number of grid points along the axes, if not otherwise specified. See *Note 2*.

**full\_output** : bool, optional

If True, return the evaluation grid and the objective function’s values on it.

**finish** : callable, optional

An optimization function that is called with the result of brute force minimization as initial guess. `finish` should take `func` and the initial guess as positional arguments, and take `args` as keyword arguments. It may additionally take `full_output` and/or `disp` as keyword arguments. Use None if no “polishing” function is to be used. See Notes for more details.

**disp** : bool, optional

Set to True to print convergence messages.

**Returns** **x0** : ndarray

A 1-D array containing the coordinates of a point at which the objective function had its minimum value. (See *Note 1* for which point is returned.)

**fval** : float

Function value at the point `x0`. (Returned when `full_output` is True.)

**grid** : tuple

Representation of the evaluation grid. It has the same length as `x0`. (Returned when `full_output` is True.)

**Jout** : ndarray

Function values at each point of the evaluation grid, i.e., `Jout = func(*grid)`. (Returned when `full_output` is True.)

**See also:**

`basinhopping`, `differential_evolution`

**Notes**

*Note 1:* The program finds the gridpoint at which the lowest value of the objective function occurs. If `finish` is None, that is the point returned. When the global minimum occurs within (or not very far outside) the grid’s

boundaries, and the grid is fine enough, that point will be in the neighborhood of the global minimum.

However, users often employ some other optimization program to “polish” the gridpoint values, *i.e.*, to seek a more precise (local) minimum near *brute*’s best gridpoint. The *brute* function’s *finish* option provides a convenient way to do that. Any polishing program used must take *brute*’s output as its initial guess as a positional argument, and take *brute*’s input values for *args* as keyword arguments, otherwise an error will be raised. It may additionally take *full\_output* and/or *disp* as keyword arguments.

*brute* assumes that the *finish* function returns either an *OptimizeResult* object or a tuple in the form:  $(x_{\min}, J_{\min}, \dots, \text{statuscode})$ , where  $x_{\min}$  is the minimizing value of the argument,  $J_{\min}$  is the minimum value of the objective function, “...” may be some other returned values (which are not used by *brute*), and *statuscode* is the status code of the *finish* program.

Note that when *finish* is not *None*, the values returned are those of the *finish* program, *not* the gridpoint ones. Consequently, while *brute* confines its search to the input grid points, the *finish* program’s results usually will not coincide with any gridpoint, and may fall outside the grid’s boundary. Thus, if a minimum only needs to be found over the provided grid points, make sure to pass in *finish=None*.

*Note 2:* The grid of points is a `numpy.mgrid` object. For *brute* the *ranges* and *Ns* inputs have the following effect. Each component of the *ranges* tuple can be either a slice object or a two-tuple giving a range of values, such as  $(0, 5)$ . If the component is a slice object, *brute* uses it directly. If the component is a two-tuple range, *brute* internally converts it to a slice object that interpolates *Ns* points from its low-value to its high-value, inclusive.

### Examples

We illustrate the use of *brute* to seek the global minimum of a function of two variables that is given as the sum of a positive-definite quadratic and two deep “Gaussian-shaped” craters. Specifically, define the objective function *f* as the sum of three other functions,  $f = f_1 + f_2 + f_3$ . We suppose each of these has a signature  $(z, \text{*params})$ , where  $z = (x, y)$ , and *params* and the functions are as defined below.

```
>>> params = (2, 3, 7, 8, 9, 10, 44, -1, 2, 26, 1, -2, 0.5)
>>> def f1(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (a * x**2 + b * x * y + c * y**2 + d*x + e*y + f)
```

```
>>> def f2(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (-g*np.exp(-((x-h)**2 + (y-i)**2) / scale))
```

```
>>> def f3(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (-j*np.exp(-((x-k)**2 + (y-l)**2) / scale))
```

```
>>> def f(z, *params):
...     return f1(z, *params) + f2(z, *params) + f3(z, *params)
```

Thus, the objective function may have local minima near the minimum of each of the three functions of which it is composed. To use *fmin* to polish its gridpoint result, we may then continue as follows:

```
>>> rranges = (slice(-4, 4, 0.25), slice(-4, 4, 0.25))
>>> from scipy import optimize
>>> resbrute = optimize.brute(f, rranges, args=params, full_output=True,
...                          finish=optimize.fmin)
>>> resbrute[0] # global minimum
```

```
array([-1.05665192,  1.80834843])
>>> resbrute[1] # function value at global minimum
-3.4085818767
```

Note that if *finish* had been set to `None`, we would have gotten the gridpoint `[-1.0 1.75]` where the rounded function value is `-2.892`.

## Rosenbrock function

<code>rosen(x)</code>	The Rosenbrock function.
<code>rosen_der(x)</code>	The derivative (i.e.
<code>rosen_hess(x)</code>	The Hessian matrix of the Rosenbrock function.
<code>rosen_hess_prod(x, p)</code>	Product of the Hessian matrix of the Rosenbrock function with a vector.

`scipy.optimize.rosen(x)`

The Rosenbrock function.

The function computed is:

```
sum(100.0*(x[1:] - x[:-1])**2.0)**2.0 + (1 - x[:-1])**2.0)
```

**Parameters** `x` : array\_like  
 1-D array of points at which the Rosenbrock function is to be computed.

**Returns** `f` : float  
 The value of the Rosenbrock function.

**See also:**

`rosen_der`, `rosen_hess`, `rosen_hess_prod`

`scipy.optimize.rosen_der(x)`

The derivative (i.e. gradient) of the Rosenbrock function.

**Parameters** `x` : array\_like  
 1-D array of points at which the derivative is to be computed.

**Returns** `rosen_der` : (N,) ndarray  
 The gradient of the Rosenbrock function at *x*.

**See also:**

`rosen`, `rosen_hess`, `rosen_hess_prod`

`scipy.optimize.rosen_hess(x)`

The Hessian matrix of the Rosenbrock function.

**Parameters** `x` : array\_like  
 1-D array of points at which the Hessian matrix is to be computed.

**Returns** `rosen_hess` : ndarray  
 The Hessian matrix of the Rosenbrock function at *x*.

**See also:**

`rosen`, `rosen_der`, `rosen_hess_prod`

`scipy.optimize.rosen_hess_prod(x, p)`

Product of the Hessian matrix of the Rosenbrock function with a vector.

**Parameters** **x** : array\_like  
 1-D array of points at which the Hessian matrix is to be computed.  
**p** : array\_like  
 1-D array, the vector to be multiplied by the Hessian matrix.

**Returns** **rosen\_hess\_prod** : ndarray  
 The Hessian matrix of the Rosenbrock function at  $x$  multiplied by the vector  $p$ .

**See also:**

`rosen`, `rosen_der`, `rosen_hess`

## 5.18.2 Fitting

---

`curve_fit(f, xdata, ydata[, p0, sigma, ...])` Use non-linear least squares to fit a function,  $f$ , to data.

---

`scipy.optimize.curve_fit(f, xdata, ydata, p0=None, sigma=None, absolute_sigma=False, check_finite=True, bounds=(-inf, inf), method=None, jac=None, **kwargs)`

Use non-linear least squares to fit a function,  $f$ , to data.

Assumes  $ydata = f(xdata, *params) + \epsilon$

**Parameters** **f** : callable  
 The model function,  $f(x, \dots)$ . It must take the independent variable as the first argument and the parameters to fit as separate remaining arguments.

**xdata** : An M-length sequence or an (k,M)-shaped array for functions with k predictors  
 The independent variable where the data is measured.

**ydata** : M-length sequence  
 The dependent data — nominally  $f(xdata, \dots)$

**p0** : None, scalar, or N-length sequence, optional  
 Initial guess for the parameters. If None, then the initial values will all be 1 (if the number of parameters for the function can be determined using introspection, otherwise a ValueError is raised).

**sigma** : None or M-length sequence or MxM array, optional  
 Determines the uncertainty in  $ydata$ . If we define residuals as  $r = ydata - f(xdata, *popt)$ , then the interpretation of  $\sigma$  depends on its number of dimensions:

- A 1-d  $\sigma$  should contain values of standard deviations of errors in  $ydata$ . In this case, the optimized function is  $chisq = \sum((r / \sigma) ** 2)$ .
- A 2-d  $\sigma$  should contain the covariance matrix of errors in  $ydata$ . In this case, the optimized function is  $chisq = r.T @ \text{inv}(\sigma) @ r$ .

New in version 0.19.  
 None (default) is equivalent of 1-d  $\sigma$  filled with ones.

**absolute\_sigma** : bool, optional  
 If True,  $\sigma$  is used in an absolute sense and the estimated parameter covariance  $pcov$  reflects these absolute values.  
 If False, only the relative magnitudes of the  $\sigma$  values matter. The returned parameter covariance matrix  $pcov$  is based on scaling  $\sigma$  by a constant factor. This constant is set by demanding that the reduced  $chisq$  for the optimal parameters  $popt$  when using the *scaled*  $\sigma$  equals unity. In other words,  $\sigma$  is scaled to match the sample variance of the residuals after the fit. Mathematically,  $pcov(\text{absolute\_sigma}=\text{False}) = pcov(\text{absolute\_sigma}=\text{True}) * chisq(popt) / (M-N)$

**check\_finite** : bool, optional

If True, check that the input arrays do not contain nans or infs, and raise a `ValueError` if they do. Setting this parameter to False may silently produce nonsensical results if the input arrays do contain nans. Default is True.

**bounds** : 2-tuple of array\_like, optional

Lower and upper bounds on independent variables. Defaults to no bounds. Each element of the tuple must be either an array with the length equal to the number of parameters, or a scalar (in which case the bound is taken to be the same for all parameters.) Use `np.inf` with an appropriate sign to disable bounds on all or some parameters.

New in version 0.17.

**method** : {'lm', 'trf', 'dogbox'}, optional

Method to use for optimization. See `least_squares` for more details. Default is 'lm' for unconstrained problems and 'trf' if `bounds` are provided. The method 'lm' won't work when the number of observations is less than the number of variables, use 'trf' or 'dogbox' in this case.

New in version 0.17.

**jac** : callable, string or None, optional

Function with signature `jac(x, ...)` which computes the Jacobian matrix of the model function with respect to parameters as a dense array\_like structure. It will be scaled according to provided `sigma`. If None (default), the Jacobian will be estimated numerically. String keywords for 'trf' and 'dogbox' methods can be used to select a finite difference scheme, see `least_squares`.

New in version 0.18.

**kwargs**

Keyword arguments passed to `leastsq` for `method='lm'` or `least_squares` otherwise.

**Returns**

**popt** : array

Optimal values for the parameters so that the sum of the squared residuals of  $f(xdata, *popt) - ydata$  is minimized

**pcov** : 2d array

The estimated covariance of `popt`. The diagonals provide the variance of the parameter estimate. To compute one standard deviation errors on the parameters use `perr = np.sqrt(np.diag(pcov))`.

How the `sigma` parameter affects the estimated covariance depends on `absolute_sigma` argument, as described above.

If the Jacobian matrix at the solution doesn't have a full rank, then 'lm' method returns a matrix filled with `np.inf`, on the other hand 'trf' and 'dogbox' methods use Moore-Penrose pseudoinverse to compute the covariance matrix.

**Raises**

**ValueError**

if either `ydata` or `xdata` contain NaNs, or if incompatible options are used.

**RuntimeError**

if the least-squares minimization fails.

**OptimizeWarning**

if covariance of the parameters can not be estimated.

See also:

**least\_squares**

Minimize the sum of squares of nonlinear functions.

**scipy.stats.linregress**

Calculate a linear least squares regression for two sets of measurements.

### Notes

With `method='lm'`, the algorithm uses the Levenberg-Marquardt algorithm through `leastsq`. Note that this algorithm can only deal with unconstrained problems.

Box constraints can be handled by methods `'trf'` and `'dogbox'`. Refer to the docstring of `least_squares` for more information.

### Examples

```
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.optimize import curve_fit
```

```
>>> def func(x, a, b, c):
...     return a * np.exp(-b * x) + c
```

Define the data to be fit with some noise:

```
>>> xdata = np.linspace(0, 4, 50)
>>> y = func(xdata, 2.5, 1.3, 0.5)
>>> np.random.seed(1729)
>>> y_noise = 0.2 * np.random.normal(size=xdata.size)
>>> ydata = y + y_noise
>>> plt.plot(xdata, ydata, 'b-', label='data')
```

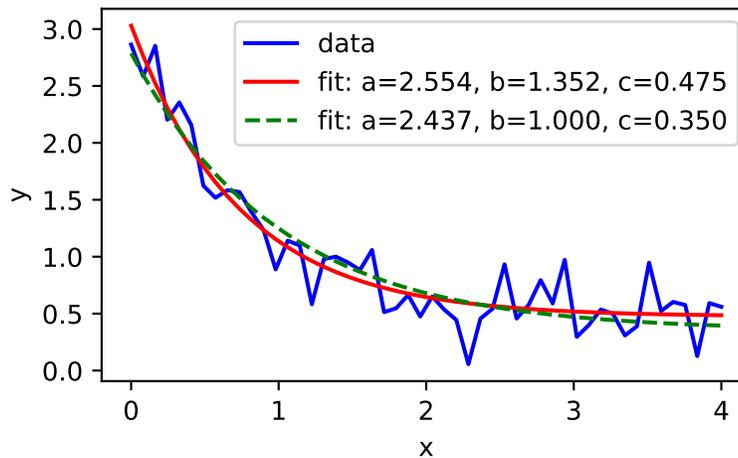

Fit for the parameters `a`, `b`, `c` of the function `func`:

```
>>> popt, pcov = curve_fit(func, xdata, ydata)
>>> popt
array([ 2.55423706,  1.35190947,  0.47450618])
>>> plt.plot(xdata, func(xdata, *popt), 'r-',
...         label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```

Constrain the optimization to the region of  $0 \leq a \leq 3, 0 \leq b \leq 1$  and  $0 \leq c \leq 0.5$ :

```
>>> popt, pcov = curve_fit(func, xdata, ydata, bounds=(0, [3., 1., 0.5]))
>>> popt
array([ 2.43708906,  1.          ,  0.35015434])
>>> plt.plot(xdata, func(xdata, *popt), 'g--',
...         label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```

```
>>> plt.xlabel('x')
>>> plt.ylabel('y')
>>> plt.legend()
>>> plt.show()
```

### 5.18.3 Root finding

#### Scalar functions

<code>brentq(f, a, b[, args, xtol, rtol, maxiter, ...])</code>	Find a root of a function in a bracketing interval using Brent's method.
<code>brenth(f, a, b[, args, xtol, rtol, maxiter, ...])</code>	Find root of $f$ in $[a, b]$ .
<code>ridder(f, a, b[, args, xtol, rtol, maxiter, ...])</code>	Find a root of a function in an interval.
<code>bisect(f, a, b[, args, xtol, rtol, maxiter, ...])</code>	Find root of a function within an interval.
<code>newton(func, x0[, fprime, args, tol, ...])</code>	Find a zero using the Newton-Raphson or secant method.

`scipy.optimize.brentq(f, a, b, args=(), xtol=2e-12, rtol=8.8817841970012523e-16, maxiter=100, full_output=False, disp=True)`

Find a root of a function in a bracketing interval using Brent's method.

Uses the classic Brent's method to find a zero of the function  $f$  on the sign changing interval  $[a, b]$ . Generally considered the best of the rootfinding routines here. It is a safe version of the secant method that uses inverse quadratic extrapolation. Brent's method combines root bracketing, interval bisection, and inverse quadratic interpolation. It is sometimes known as the van Wijngaarden-Dekker-Brent method. Brent (1973) claims convergence is guaranteed for functions computable within  $[a, b]$ .

[Brent1973] provides the classic description of the algorithm. Another description can be found in a recent edition of Numerical Recipes, including [PressEtal1992]. Another description is at <http://mathworld.wolfram.com/BrentsMethod.html>. It should be easy to understand the algorithm just by reading our code. Our code diverges a bit from standard presentations: we choose a different formula for the extrapolation step.

**Parameters**

- f** : function  
Python function returning a number. The function  $f$  must be continuous, and  $f(a)$  and  $f(b)$  must have opposite signs.
- a** : number  
One end of the bracketing interval  $[a, b]$ .
- b** : number  
The other end of the bracketing interval  $[a, b]$ .
- xtol** : number, optional

The computed root  $x_0$  will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where  $x$  is the exact root. The parameter must be nonnegative. For nice functions, Brent's method will often satisfy the above condition with  $xtol/2$  and  $rtol/2$ . [Brent1973]

**rtol** : number, optional

The computed root  $x_0$  will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where  $x$  is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`. For nice functions, Brent's method will often satisfy the above condition with  $xtol/2$  and  $rtol/2$ . [Brent1973]

**maxiter** : number, optional

if convergence is not achieved in `maxiter` iterations, an error is raised. Must be  $\geq 0$ .

**args** : tuple, optional

containing extra arguments for the function  $f$ .  $f$  is called by `apply(f, (x)+args)`.

**full\_output** : bool, optional

If `full_output` is `False`, the root is returned. If `full_output` is `True`, the return value is  $(x, r)$ , where  $x$  is the root, and  $r$  is a `RootResults` object.

**disp** : bool, optional

If `True`, raise `RuntimeError` if the algorithm didn't converge.

#### Returns

**x0** : float

Zero of  $f$  between  $a$  and  $b$ .

**r** : `RootResults` (present if `full_output = True`)

Object containing information about the convergence. In particular, `r.converged` is `True` if the routine converged.

#### Examples

```
>>> def f(x):
...     return (x**2 - 1)
```

```
>>> from scipy import optimize
```

```
>>> root = optimize.brentq(f, -2, 0)
>>> root
-1.0
```

```
>>> root = optimize.brentq(f, 0, 2)
>>> root
1.0
```

`scipy.optimize.brenth`(*f*, *a*, *b*, *args*=(), *xtol*= $2e-12$ , *rtol*= $8.8817841970012523e-16$ , *maxiter*=100, *full\_output*=False, *disp*=True)

Find root of *f* in [*a*,*b*].

A variation on the classic Brent routine to find a zero of the function *f* between the arguments *a* and *b* that uses hyperbolic extrapolation instead of inverse quadratic extrapolation. There was a paper back in the 1980's ... *f*(*a*) and *f*(*b*) cannot have the same signs. Generally on a par with the *brent* routine, but not as heavily tested. It is a safe version of the secant method that uses hyperbolic extrapolation. The version here is by Chuck Harris.

**Parameters**

- f** : function  
Python function returning a number. *f* must be continuous, and *f*(*a*) and *f*(*b*) must have opposite signs.
- a** : number  
One end of the bracketing interval [*a*,*b*].
- b** : number  
The other end of the bracketing interval [*a*,*b*].
- xtol** : number, optional  
The computed root *x0* will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where *x* is the exact root. The parameter must be nonnegative. As with *brentq*, for nice functions the method will often satisfy the above condition with *xtol*/2 and *rtol*/2.
- rtol** : number, optional  
The computed root *x0* will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where *x* is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`. As with *brentq*, for nice functions the method will often satisfy the above condition with *xtol*/2 and *rtol*/2.
- maxiter** : number, optional  
if convergence is not achieved in *maxiter* iterations, an error is raised. Must be  $\geq 0$ .
- args** : tuple, optional  
containing extra arguments for the function *f*. *f* is called by `apply(f, (x)+args)`.
- full\_output** : bool, optional  
If *full\_output* is False, the root is returned. If *full\_output* is True, the return value is (*x*, *r*), where *x* is the root, and *r* is a RootResults object.
- disp** : bool, optional  
If True, raise RuntimeError if the algorithm didn't converge.

**Returns**

- x0** : float  
Zero of *f* between *a* and *b*.
- r** : RootResults (present if *full\_output* = True)  
Object containing information about the convergence. In particular, *r.converged* is True if the routine converged.

### Examples

```
>>> def f(x):
...     return (x**2 - 1)
```

```
>>> from scipy import optimize
```

```
>>> root = optimize.brenth(f, -2, 0)
>>> root
-1.0
```

```
>>> root = optimize.brenth(f, 0, 2)
>>> root
1.0
```

`scipy.optimize.ridder(f, a, b, args=(), xtol=2e-12, rtol=8.8817841970012523e-16, maxiter=100, full_output=False, disp=True)`

Find a root of a function in an interval.

**Parameters**

- f**: function  
Python function returning a number. *f* must be continuous, and *f*(*a*) and *f*(*b*) must have opposite signs.
- a**: number  
One end of the bracketing interval [*a*,*b*].
- b**: number  
The other end of the bracketing interval [*a*,*b*].
- xtol**: number, optional  
The computed root *x0* will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where *x* is the exact root. The parameter must be nonnegative.
- rtol**: number, optional  
The computed root *x0* will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where *x* is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`.
- maxiter**: number, optional  
if convergence is not achieved in *maxiter* iterations, an error is raised. Must be  $\geq 0$ .
- args**: tuple, optional  
containing extra arguments for the function *f*. *f* is called by `apply(f, (x)+args)`.
- full\_output**: bool, optional  
If *full\_output* is False, the root is returned. If *full\_output* is True, the return value is (*x*, *r*), where *x* is the root, and *r* is a RootResults object.
- disp**: bool, optional  
If True, raise RuntimeError if the algorithm didn't converge.

**Returns**

- x0**: float  
Zero of *f* between *a* and *b*.
- r**: RootResults (present if `full_output = True`)

Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

**See also:**

`brentq`, `brenth`, `bisect`, `newton`

**fixed\_point**

scalar fixed-point finder

**Notes**

Uses [Ridders1979] method to find a zero of the function  $f$  between the arguments  $a$  and  $b$ . Ridders' method is faster than bisection, but not generally as fast as the Brent routines. [Ridders1979] provides the classic description and source of the algorithm. A description can also be found in any recent edition of Numerical Recipes.

The routine used here diverges slightly from standard presentations in order to be a bit more careful of tolerance.

**References**

[Ridders1979]

**Examples**

```
>>> def f(x):
...     return (x**2 - 1)
```

```
>>> from scipy import optimize
```

```
>>> root = optimize.ridder(f, 0, 2)
>>> root
1.0
```

```
>>> root = optimize.ridder(f, -2, 0)
>>> root
-1.0
```

`scipy.optimize.bisect` ( $f$ ,  $a$ ,  $b$ ,  $args=()$ ,  $xtol=2e-12$ ,  $rtol=8.8817841970012523e-16$ ,  $maxiter=100$ ,  $full_output=False$ ,  $disp=True$ )

Find root of a function within an interval.

Basic bisection routine to find a zero of the function  $f$  between the arguments  $a$  and  $b$ .  $f(a)$  and  $f(b)$  cannot have the same signs. Slow but sure.

**Parameters**

- f**: function  
Python function returning a number.  $f$  must be continuous, and  $f(a)$  and  $f(b)$  must have opposite signs.
- a**: number  
One end of the bracketing interval  $[a,b]$ .
- b**: number  
The other end of the bracketing interval  $[a,b]$ .
- xtol**: number, optional  
The computed root  $x_0$  will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where  $x$  is the exact root. The parameter must be nonnegative.
- rtol**: number, optional  
The computed root  $x_0$  will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where  $x$  is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`.

**maxiter** : number, optional  
if convergence is not achieved in *maxiter* iterations, an error is raised. Must be  $\geq 0$ .

**args** : tuple, optional  
containing extra arguments for the function *f*. *f* is called by `apply(f, (x)+args)`.

**full\_output** : bool, optional  
If *full\_output* is False, the root is returned. If *full\_output* is True, the return value is `(x, r)`, where *x* is the root, and *r* is a *RootResults* object.

**disp** : bool, optional  
If True, raise RuntimeError if the algorithm didn't converge.

**Returns**

**x0** : float  
Zero of *f* between *a* and *b*.

**r** : RootResults (present if `full_output = True`)  
Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

```

`scipy.optimize.newton` (*func*, *x0*, *fprime*=None, *args*=(), *tol*=1.48e-08, *maxiter*=50, *fprime2*=None)

Find a zero using the Newton-Raphson or secant method.

Find a zero of the function *func* given a nearby starting point *x0*. The Newton-Raphson method is used if the derivative *fprime* of *func* is provided, otherwise the secant method is used. If the second order derivate *fprime2* of *func* is provided, parabolic Halley's method is used.

**Parameters**

**func** : function

The function whose zero is wanted. It must be a function of a single variable of the form `f(x,a,b,c,...)`, where `a,b,c...` are extra arguments that can be passed in the `args` parameter.

**x0** : float

An initial estimate of the zero that should be somewhere near the actual zero.

**fprime** : function, optional

The derivative of the function when available and convenient. If it is None (default), then the secant method is used.

**args** : tuple, optional

Extra arguments to be used in the function call.

**tol** : float, optional  
The allowable error of the zero value.

**maxiter** : int, optional  
Maximum number of iterations.

**fprime2** : function, optional  
The second order derivative of the function when available and convenient. If it is None (default), then the normal Newton-Raphson or the secant method is used. If it is given, parabolic Halley's method is used.

**Returns** **zero** : float  
Estimated location where function is zero.

**See also:**

*brentq, brenth, ridder, bisect*

**fsolve** find zeroes in n dimensions.

**Notes**

The convergence rate of the Newton-Raphson method is quadratic, the Halley method is cubic, and the secant method is sub-quadratic. This means that if the function is well behaved the actual error in the estimated zero is approximately the square (cube for Halley) of the requested tolerance up to roundoff error. However, the stopping criterion used here is the step size and there is no guarantee that a zero has been found. Consequently the result should be verified. Safer algorithms are *brentq*, *brenth*, *ridder*, and *bisect*, but they all require that the root first be bracketed in an interval where the function changes sign. The *brentq* algorithm is recommended for general use in one dimensional problems when such an interval has been found.

**Examples**

```
>>> def f(x):
...     return (x**3 - 1) # only one real root at x = 1
```

```
>>> from scipy import optimize
```

fprime and fprime2 not provided, use secant method

```
>>> root = optimize.newton(f, 1.5)
>>> root
1.00000000000000016
```

Only fprime provided, use Newton Raphson method

```
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2)
>>> root
1.0
```

fprime2 provided, fprime provided/not provided use parabolic Halley's method

```
>>> root = optimize.newton(f, 1.5, fprime2=lambda x: 6 * x)
>>> root
1.00000000000000016
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2,
...                          fprime2=lambda x: 6 * x)
>>> root
1.0
```

Fixed point finding:

---

<code>fixed_point(func, x0[, args, xtol, maxiter, ...])</code>	Find a fixed point of the function.
--	-------------------------------------

---

`scipy.optimize.fixed_point` (*func*, *x0*, *args*=(), *xtol*=1e-08, *maxiter*=500, *method*='del2')

Find a fixed point of the function.

Given a function of one or more variables and a starting point, find a fixed-point of the function: i.e. where `func(x0) == x0`.

**Parameters**

- func** : function  
Function to evaluate.
- x0** : array\_like  
Fixed point of function.
- args** : tuple, optional  
Extra arguments to *func*.
- xtol** : float, optional  
Convergence tolerance, defaults to 1e-08.
- maxiter** : int, optional  
Maximum number of iterations, defaults to 500.
- method** : {"del2", "iteration"}, optional  
Method of finding the fixed-point, defaults to "del2" which uses Steffensen's Method with Aitken's Del<sup>2</sup> convergence acceleration [R197]. The "iteration" method simply iterates the function until convergence is detected, without attempting to accelerate the convergence.

### References

[R197]

### Examples

```
>>> from scipy import optimize
>>> def func(x, c1, c2):
...     return np.sqrt(c1/(x+c2))
>>> c1 = np.array([10, 12.])
>>> c2 = np.array([3, 5.])
>>> optimize.fixed_point(func, [1.2, 1.3], args=(c1, c2))
array([ 1.4920333 ,  1.37228132])
```

## Multidimensional

General nonlinear solvers:

<code>root(func, x0[, args, method, jac, tol, ...])</code>	Find a root of a vector function.
<code>fsolve(func, x0[, args, fprime, ...])</code>	Find the roots of a function.
<code>broyden1(F, xin[, iter, alpha, ...])</code>	Find a root of a function, using Broyden's first Jacobian approximation.
<code>broyden2(F, xin[, iter, alpha, ...])</code>	Find a root of a function, using Broyden's second Jacobian approximation.

---

`scipy.optimize.root` (*fun*, *x0*, *args*=(), *method*='hybr', *jac*=None, *tol*=None, *callback*=None, *options*=None)

Find a root of a vector function.

**Parameters** **fun** : callable

A vector function to find a root of.

**x0** : ndarray

Initial guess.

**args** : tuple, optional

Extra arguments passed to the objective function and its Jacobian.

**method** : str, optional

Type of solver. Should be one of

- 'hybr' (*see here*)
- 'lm' (*see here*)
- 'broyden1' (*see here*)
- 'broyden2' (*see here*)
- 'anderson' (*see here*)
- 'linearmixing' (*see here*)
- 'diagbroyden' (*see here*)
- 'excitingmixing' (*see here*)
- 'krylov' (*see here*)
- 'df-sane' (*see here*)

**jac** : bool or callable, optional

If *jac* is a Boolean and is True, *fun* is assumed to return the value of Jacobian along with the objective function. If False, the Jacobian will be estimated numerically. *jac* can also be a callable returning the Jacobian of *fun*. In this case, it must accept the same arguments as *fun*.

**tol** : float, optional

Tolerance for termination. For detailed control, use solver-specific options.

**callback** : function, optional

Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual. For all methods but 'hybr' and 'lm'.

**options** : dict, optional

A dictionary of solver options. E.g. *xtol* or *maxiter*, see `show_options()` for details.

**Returns**

**sol** : OptimizeResult

The solution represented as a `OptimizeResult` object. Important attributes are: *x* the solution array, *success* a Boolean flag indicating if the algorithm exited successfully and *message* which describes the cause of the termination. See `OptimizeResult` for a description of other attributes.

**See also:**

**show\_options**

Additional options accepted by the solvers

**Notes**

This section describes the available solvers that can be selected by the 'method' parameter. The default method is *hybr*.

Method *hybr* uses a modification of the Powell hybrid method as implemented in MINPACK [R221].

Method *lm* solves the system of nonlinear equations in a least squares sense using a modification of the Levenberg-Marquardt algorithm as implemented in MINPACK [R221].

Method *df-sane* is a derivative-free spectral method. [R223]

Methods *broyden1*, *broyden2*, *anderson*, *linearmixing*, *diagbroyden*, *excitingmixing*, *krylov* are inexact Newton methods, with backtracking or full line searches [R222]. Each method corresponds to a particular Jacobian approximations. See *nonlin* for details.

- Method *broyden1* uses Broyden's first Jacobian approximation, it is known as Broyden's good method.
- Method *broyden2* uses Broyden's second Jacobian approximation, it is known as Broyden's bad method.
- Method *anderson* uses (extended) Anderson mixing.
- Method *Krylov* uses Krylov approximation for inverse Jacobian. It is suitable for large-scale problem.
- Method *diagbroyden* uses diagonal Broyden Jacobian approximation.
- Method *linearmixing* uses a scalar Jacobian approximation.
- Method *excitingmixing* uses a tuned diagonal Jacobian approximation.

**Warning:** The algorithms implemented for methods *diagbroyden*, *linearmixing* and *excitingmixing* may be useful for specific problems, but whether they will work may depend strongly on the problem.

New in version 0.11.0.

### Examples

The following functions define a system of nonlinear equations and its jacobian.

```
>>> def fun(x):
...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...            0.5 * (x[1] - x[0])**3 + x[1]]
```

```
>>> def jac(x):
...     return np.array([[1 + 1.5 * (x[0] - x[1])**2,
...                      -1.5 * (x[0] - x[1])**2],
...                     [-1.5 * (x[1] - x[0])**2,
...                      1 + 1.5 * (x[1] - x[0])**2]])
```

A solution can be obtained as follows.

```
>>> from scipy import optimize
>>> sol = optimize.root(fun, [0, 0], jac=jac, method='hybr')
>>> sol.x
array([ 0.8411639,  0.1588361])
```

`scipy.optimize.fsolve` (*func*, *x0*, *args=()*, *fprime=None*, *full\_output=0*, *col\_deriv=0*, *xtol=1.49012e-08*, *maxfev=0*, *band=None*, *epsfcn=None*, *factor=100*, *diag=None*)

Find the roots of a function.

Return the roots of the (non-linear) equations defined by  $\text{func}(x) = 0$  given a starting estimate.

- Parameters**
- func** : callable  $f(x, *args)$   
A function that takes at least one (possibly vector) argument.
  - x0** : ndarray  
The starting estimate for the roots of  $\text{func}(x) = 0$ .
  - args** : tuple, optional  
Any extra arguments to *func*.
  - fprime** : callable  $f(x, *args)$ , optional  
A function to compute the Jacobian of *func* with derivatives across the rows. By default, the Jacobian will be estimated.

**full\_output** : bool, optional  
 If True, return optional outputs.

**col\_deriv** : bool, optional  
 Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).

**xtol** : float, optional  
 The calculation will terminate if the relative error between two consecutive iterates is at most *xtol*.

**maxfev** : int, optional  
 The maximum number of calls to the function. If zero, then  $100 * (N+1)$  is the maximum where N is the number of elements in *x0*.

**band** : tuple, optional  
 If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for *fprime=None*).

**epsfcn** : float, optional  
 A suitable step length for the forward-difference approximation of the Jacobian (for *fprime=None*). If *epsfcn* is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.

**factor** : float, optional  
 A parameter determining the initial step bound ( $factor * ||diag * x||$ ). Should be in the interval (0.1, 100).

**diag** : sequence, optional  
 N positive entries that serve as a scale factors for the variables.

**Returns**

**x** : ndarray  
 The solution (or the result of the last iteration for an unsuccessful call).

**infodict** : dict  
 A dictionary of optional outputs with the keys:

<b>nfev</b>	number of function calls
<b>njev</b>	number of Jacobian calls
<b>fvec</b>	function evaluated at the output
<b>fjac</b>	the orthogonal matrix, q, produced by the QR factorization of the final approximate Jacobian matrix, stored column wise
<b>r</b>	upper triangular matrix produced by QR factorization of the same matrix
<b>qtf</b>	the vector ( $transpose(q) * fvec$ )

**ier** : int  
 An integer flag. Set to 1 if a solution was found, otherwise refer to *mesg* for more information.

**mesg** : str  
 If no solution is found, *mesg* details the cause of failure.

**See also:**

**root**      Interface to root finding algorithms for multivariate functions.

**Notes**

*fsolve* is a wrapper around MINPACK's *hybrd* and *hybrj* algorithms.

```
scipy.optimize.broyden1(F, xin, iter=None, alpha=None, reduction_method='restart',
                        max_rank=None, verbose=False, maxiter=None, f_tol=None,
                        f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None,
                        line_search='armijo', callback=None, **kw)
```

Find a root of a function, using Broyden's first Jacobian approximation.

This method is also known as “Broyden’s good method”.

<b>Parameters</b>	<p><b>F</b> : function(x) -&gt; f Function whose root to find; should take and return an array-like object.</p> <p><b>xin</b> : array_like Initial guess for the solution</p> <p><b>alpha</b> : float, optional Initial guess for the Jacobian is <math>(-1/\text{alpha})</math>.</p> <p><b>reduction_method</b> : str or tuple, optional Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters. Methods available:</p> <ul style="list-style-type: none"> <li>•restart: drop all matrix columns. Has no extra parameters.</li> <li>•simple: drop oldest matrix column. Has no extra parameters.</li> <li>•svd: keep only the most significant SVD components. Takes an extra parameter, to_retain, which determines the number of SVD components to retain when rank reduction is done. Default is <code>max_rank - 2</code>.</li> </ul> <p><b>max_rank</b> : int, optional Maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).</p> <p><b>iter</b> : int, optional Number of iterations to make. If omitted (default), make as many as required to meet tolerances.</p> <p><b>verbose</b> : bool, optional Print status to stdout on every iteration.</p> <p><b>maxiter</b> : int, optional Maximum number of iterations to make. If more are needed to meet convergence, <i>NoConvergence</i> is raised.</p> <p><b>f_tol</b> : float, optional Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.</p> <p><b>f_rtol</b> : float, optional Relative tolerance for the residual. If omitted, not used.</p> <p><b>x_tol</b> : float, optional Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.</p> <p><b>x_rtol</b> : float, optional Relative minimum step size. If omitted, not used.</p> <p><b>tol_norm</b> : function(vector) -&gt; scalar, optional Norm to use in convergence check. Default is the maximum norm.</p> <p><b>line_search</b> : {None, ‘armijo’ (default), ‘wolfe’}, optional Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.</p> <p><b>callback</b> : function, optional Optional callback function. It is called on every iteration as <code>callback(x, f)</code> where <i>x</i> is the current solution and <i>f</i> the corresponding residual.</p>
<b>Returns</b>	<p><b>sol</b> : ndarray An array (of similar array type as <i>x0</i>) containing the final solution.</p>
<b>Raises</b>	<p><b>NoConvergence</b> When a solution was not found.</p>

**Notes**

This algorithm implements the inverse Jacobian Quasi-Newton update

$$H_+ = H + (dx - Hdf)dx^\dagger H / (dx^\dagger Hdf)$$

which corresponds to Broyden's first Jacobian update

$$J_+ = J + (df - Jdx)dx^\dagger / dx^\dagger dx$$

**References**

[R192]

```
scipy.optimize.broyden2(F, xin, iter=None, alpha=None, reduction_method='restart',
                        max_rank=None, verbose=False, maxiter=None, f_tol=None,
                        f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None,
                        line_search='armijo', callback=None, **kw)
```

Find a root of a function, using Broyden's second Jacobian approximation.

This method is also known as "Broyden's bad method".

**Parameters**

**F** : function(x) -> f

Function whose root to find; should take and return an array-like object.

**xin** : array\_like

Initial guess for the solution

**alpha** : float, optional

Initial guess for the Jacobian is  $(-1/\alpha)$ .

**reduction\_method** : str or tuple, optional

Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.

Methods available:

- restart: drop all matrix columns. Has no extra parameters.
- simple: drop oldest matrix column. Has no extra parameters.
- svd: keep only the most significant SVD components. Takes an extra parameter, to\_retain, which determines the number of SVD components to retain when rank reduction is done. Default is max\_rank - 2.

**max\_rank** : int, optional

Maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).

**iter** : int, optional

Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

**verbose** : bool, optional

Print status to stdout on every iteration.

**maxiter** : int, optional

Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

**f\_tol** : float, optional

Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

**f\_rtol** : float, optional

Relative tolerance for the residual. If omitted, not used.

**x\_tol** : float, optional

Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

**x\_rtol** : float, optional  
Relative minimum step size. If omitted, not used.

**tol\_norm** : function(vector) -> scalar, optional  
Norm to use in convergence check. Default is the maximum norm.

**line\_search** : {None, 'armijo' (default), 'wolfe'}, optional  
Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

**callback** : function, optional  
Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns** **sol** : ndarray  
An array (of similar array type as `x0`) containing the final solution.

**Raises** **NoConvergence**  
When a solution was not found.

### Notes

This algorithm implements the inverse Jacobian Quasi-Newton update

$$H_+ = H + (dx - Hdf)df^\dagger / (df^\dagger df)$$

corresponding to Broyden's second method.

The `root` function supports the following methods:

#### `root(method='hybr')`

`scipy.optimize.root` (*fun*, *x0*, *args=()*, *method='hybr'*, *jac=None*, *tol=None*, *callback=None*, *options={'col\_deriv': 0, 'diag': None, 'factor': 100, 'eps': None, 'band': None, 'func': None, 'maxfev': 0, 'xtol': 1.49012e-08}*)

Find the roots of a multivariate function using MINPACK's `hybrd` and `hybrj` routines (modified Powell method).

#### See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options** **col\_deriv** : bool  
Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).

**xtol** : float  
The calculation will terminate if the relative error between two consecutive iterates is at most `xtol`.

**maxfev** : int  
The maximum number of calls to the function. If zero, then `100 * (N+1)` is the maximum where `N` is the number of elements in `x0`.

**band** : tuple  
If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for `fprime=None`).

**eps** : float  
A suitable step length for the forward-difference approximation of the Jacobian (for `fprime=None`). If `eps` is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.

**factor** : float

A parameter determining the initial step bound (`factor * ||diag * x||`). Should be in the interval  $(0.1, 100)$ .

**diag** : sequence  
N positive entries that serve as a scale factors for the variables.

***root(method='lm')***

`scipy.optimize.root` (*fun*, *x0*, *args=()*, *method='lm'*, *jac=None*, *tol=None*, *callback=None*, *options={'col\_deriv': 0, 'diag': None, 'factor': 100, 'gtol': 0.0, 'eps': 0.0, 'func': None, 'maxiter': 0, 'xtol': 1.49012e-08, 'ftol': 1.49012e-08}*)

Solve for least squares with Levenberg-Marquardt

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- col\_deriv** : bool  
non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- ftol** : float  
Relative error desired in the sum of squares.
- xtol** : float  
Relative error desired in the approximate solution.
- gtol** : float  
Orthogonality desired between the function vector and the columns of the Jacobian.
- maxiter** : int  
The maximum number of calls to the function. If zero, then  $100*(N+1)$  is the maximum where N is the number of elements in *x0*.
- epsfcn** : float  
A suitable step length for the forward-difference approximation of the Jacobian (for *Dfun=None*). If *epsfcn* is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.
- factor** : float  
A parameter determining the initial step bound (`factor * ||diag * x||`). Should be in interval  $(0.1, 100)$ .
- diag** : sequence  
N positive entries that serve as a scale factors for the variables.

***root(method='broyden1')***

`scipy.optimize.root` (*fun*, *x0*, *args=()*, *method='broyden1'*, *tol=None*, *callback=None*, *options={}*)

**Options**

- nit** : int, optional  
Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- disp** : bool, optional  
Print status to stdout on every iteration.
- maxiter** : int, optional  
Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.
- ftol** : float, optional  
Relative tolerance for the residual. If omitted, not used.

**fatol** : float, optional  
 Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

**xtol** : float, optional  
 Relative minimum step size. If omitted, not used.

**xatol** : float, optional  
 Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

**tol\_norm** : function(vector) -> scalar, optional  
 Norm to use in convergence check. Default is the maximum norm.

**line\_search** : {None, 'armijo' (default), 'wolfe'}, optional  
 Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

**jac\_options** : dict, optional  
*Options for the respective Jacobian approximation.*

**alpha** [float, optional] Initial guess for the Jacobian is (-1/alpha).

**reduction\_method** [str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.

*Methods available:*

• **restart**: drop all matrix columns. Has no

extra parameters.

• **simple**: drop oldest matrix column. Has no

extra parameters.

• **svd**: keep only the most significant SVD

components.

*Extra parameters:*

**-to\_retain**: number of SVD compon

retain when rank reduction is done. Default is max\_rank - 2.

**max\_rank** [int, optional] Maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).

*root(method='broyden2')*

`scipy.optimize.root` (*fun*, *x0*, *args=()*, *method='broyden2'*, *tol=None*, *callback=None*, *options={}*)

- Options**
- nit** : int, optional  
Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
  - disp** : bool, optional  
Print status to stdout on every iteration.
  - maxiter** : int, optional  
Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.
  - ftol** : float, optional  
Relative tolerance for the residual. If omitted, not used.
  - fatol** : float, optional  
Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
  - xtol** : float, optional  
Relative minimum step size. If omitted, not used.
  - xatol** : float, optional  
Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
  - tol\_norm** : function(vector) -> scalar, optional  
Norm to use in convergence check. Default is the maximum norm.
  - line\_search** : {None, 'armijo' (default), 'wolfe'}, optional  
Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
  - jac\_options** : dict, optional  
Options for the respective Jacobian approximation.
  - alpha** : [float, optional] Initial guess for the Jacobian is (-1/alpha).
  - M** : [float, optional] Number of previous vectors to retain. Defaults to 5.

**w0** [float, optional] Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.

**Options**

- nit** : int, optional  
Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- disp** : bool, optional  
Print status to stdout on every iteration.
- maxiter** : int, optional  
Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.
- ftol** : float, optional  
Relative tolerance for the residual. If omitted, not used.
- fatol** : float, optional  
Absolute tolerance (in max-norm) for the residual. If omitted, default is  $6e-6$ .
- xtol** : float, optional  
Relative minimum step size. If omitted, not used.
- xatol** : float, optional  
Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- tol\_norm** : function(vector) -> scalar, optional  
Norm to use in convergence check. Default is the maximum norm.
- line\_search** : {None, 'armijo' (default), 'wolfe'}, optional  
Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
- jac\_options** : dict, optional  
Options for the respective Jacobian approximation.
- rdiff*** [float, optional] Relative step size to use in numerical differentiation.
- method*** [{ 'lgmres', 'gmres', 'bicgstab', 'cgs', 'minres' } or function]  
Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in `scipy.sparse.linalg`.
- inner\_M*** [LinearOperator or InverseJacobian]  
The default is `scipy.sparse.linalg.lgmres`.  
Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,

```

>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=jac.
    ↪inverse).
```

If the preconditioner has a method named 'update', it will be called as `update(x, f)` after each nonlinear step, with `x` giving the current point, and `f` the current function value.

*inner\_tol, inner\_maxiter, ...*

Parameters to pass on to the “inner” Krylov solver. See

*outer\_k* `scipy.sparse.linalg.gmres` for details.  
[int, optional] Size of the subspace kept across LGMRES  
nonlinear iterations.

See `scipy.sparse.linalg.lgmres` for details.

***root(method='df-sane')***

`scipy.optimize.root` (*fun*, *x0*, *args=()*, *method='df-sane'*, *tol=None*, *callback=None*, *options={ 'disp': False, 'fnorm': None, 'sigma\_0': 1.0, 'eta\_strategy': None, 'sigma\_eps': 1e-10, 'M': 10, 'line\_search': 'cruz', 'fatol': 1e-300, 'func': None, 'maxfev': 1000, 'ftol': 1e-08}*)

Solve nonlinear equation with the DF-SANE method

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

**ftol** : float, optional  
Relative norm tolerance.

**fatol** : float, optional  
Absolute norm tolerance. Algorithm terminates when  $\|func(x)\| < fatol + ftol \|func(x_0)\|$ .

**fnorm** : callable, optional  
Norm to use in the convergence check. If None, 2-norm is used.

**maxfev** : int, optional  
Maximum number of function evaluations.

**disp** : bool, optional  
Whether to print convergence process to stdout.

**eta\_strategy** : callable, optional  
Choice of the `eta_k` parameter, which gives slack for growth of  $\|F\|^{**2}$ . Called as `eta_k = eta_strategy(k, x, F)` with `k` the iteration number, `x` the current iterate and `F` the current residual. Should satisfy `eta_k > 0` and `sum(eta, k=0..inf) < inf`. Default:  $\|F\|^{**2} / (1 + k)^{**2}$ .

**sigma\_eps** : float, optional  
The spectral coefficient is constrained to  $sigma\_eps < sigma < 1/sigma\_eps$ . Default: 1e-10

**sigma\_0** : float, optional  
Initial spectral coefficient. Default: 1.0

**M** : int, optional  
Number of iterates to include in the nonmonotonic line search. Default: 10

**line\_search** : {'cruz', 'cheng'}  
Type of line search to employ. 'cruz' is the original one defined in [Martinez & Raydan. Math. Comp. 75, 1429 (2006)], 'cheng' is a modified search defined in [Cheng & Li. IMA J. Numer. Anal. 29, 814 (2009)]. Default: 'cruz'

Large-scale nonlinear solvers:

Continued on next page

Table 5.127 – continued from previous page

<code>newton_krylov(F, xin[, iter, rdiff, method, ...])</code>	Find a root of a function, using Krylov approximation for inverse Jacobian.
<code>anderson(F, xin[, iter, alpha, w0, M, ...])</code>	Find a root of a function, using (extended) Anderson mixing.

```
scipy.optimize.newton_krylov(F, xin, iter=None, rdiff=None, method='lgmres',
                             inner_maxiter=20, inner_M=None, outer_k=10, verbose=False,
                             maxiter=None, f_tol=None, f_rtol=None, x_tol=None,
                             x_rtol=None, tol_norm=None, line_search='armijo',
                             callback=None, **kw)
```

Find a root of a function, using Krylov approximation for inverse Jacobian.

This method is suitable for solving large-scale problems.

**Parameters**

- F** : function(x) -> f  
Function whose root to find; should take and return an array-like object.
- xin** : array\_like  
Initial guess for the solution
- rdiff** : float, optional  
Relative step size to use in numerical differentiation.
- method** : {'lgmres', 'gmres', 'bicgstab', 'cgs', 'minres'} or function  
Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in `scipy.sparse.linalg`. The default is `scipy.sparse.linalg.lgmres`.
- inner\_M** : LinearOperator or InverseJacobian  
Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,

```
>>> from scipy.optimize.nonlin import BroydenFirst, \
↳KrylovJacobian
>>> from scipy.optimize.nonlin import InverseJacobian
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=InverseJacobian(jac))
```

If the preconditioner has a method named 'update', it will be called as `update(x, f)` after each nonlinear step, with `x` giving the current point, and `f` the current function value.

**inner\_tol, inner\_maxiter, ...**

Parameters to pass on to the "inner" Krylov solver. See `scipy.sparse.linalg.gmres` for details.

**outer\_k** : int, optional

Size of the subspace kept across LGMRES nonlinear iterations. See `scipy.sparse.linalg.lgmres` for details.

**iter** : int, optional

Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

**verbose** : bool, optional

Print status to stdout on every iteration.

**maxiter** : int, optional

Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

**f\_tol** : float, optional

Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

**f\_rtol** : float, optional  
Relative tolerance for the residual. If omitted, not used.

**x\_tol** : float, optional  
Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

**x\_rtol** : float, optional  
Relative minimum step size. If omitted, not used.

**tol\_norm** : function(vector) -> scalar, optional  
Norm to use in convergence check. Default is the maximum norm.

**line\_search** : {None, 'armijo' (default), 'wolfe'}, optional  
Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

**callback** : function, optional  
Optional callback function. It is called on every iteration as `callback(x, f)` where  $x$  is the current solution and  $f$  the corresponding residual.

**Returns** **sol** : ndarray  
An array (of similar array type as  $x_0$ ) containing the final solution.

**Raises** **NoConvergence**  
When a solution was not found.

**See also:**

`scipy.sparse.linalg.gmres`, `scipy.sparse.linalg.lgmres`

**Notes**

This function implements a Newton-Krylov solver. The basic idea is to compute the inverse of the Jacobian with an iterative Krylov method. These methods require only evaluating the Jacobian-vector products, which are conveniently approximated by a finite difference:

$$Jv \approx (f(x + \omega * v/|v|) - f(x))/\omega$$

Due to the use of iterative matrix inverses, these methods can deal with large nonlinear problems.

Scipy's `scipy.sparse.linalg` module offers a selection of Krylov solvers to choose from. The default here is `lgmres`, which is a variant of restarted GMRES iteration that reuses some of the information obtained in the previous Newton steps to invert Jacobians in subsequent steps.

For a review on Newton-Krylov methods, see for example [R219], and for the LGMRES sparse inverse method, see [R220].

```

Find a root of a function, using (extended) Anderson mixing.

The Jacobian is formed by for a 'best' solution in the space spanned by last  $M$  vectors. As a result, only a  $M \times M$  matrix inversions and  $M \times N$  multiplications are required. [Ey]

**Parameters** **F** : function(x) -> f  
Function whose root to find; should take and return an array-like object.

**xin** : array\_like

Initial guess for the solution

**alpha** : float, optional  
Initial guess for the Jacobian is (-1/alpha).

**M** : float, optional  
Number of previous vectors to retain. Defaults to 5.

**w0** : float, optional  
Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.

**iter** : int, optional  
Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

**verbose** : bool, optional  
Print status to stdout on every iteration.

**maxiter** : int, optional  
Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

**f\_tol** : float, optional  
Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

**f\_rtol** : float, optional  
Relative tolerance for the residual. If omitted, not used.

**x\_tol** : float, optional  
Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

**x\_rtol** : float, optional  
Relative minimum step size. If omitted, not used.

**tol\_norm** : function(vector) -> scalar, optional  
Norm to use in convergence check. Default is the maximum norm.

**line\_search** : {None, 'armijo' (default), 'wolfe'}, optional  
Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

**callback** : function, optional  
Optional callback function. It is called on every iteration as `callback(x, f)` where  $x$  is the current solution and  $f$  the corresponding residual.

**Returns** **sol** : ndarray  
An array (of similar array type as  $x0$ ) containing the final solution.

**Raises** **NoConvergence**  
When a solution was not found.

Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
- callback** : function, optional  
Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual.

**Returns**

- sol** : ndarray  
An array (of similar array type as *x0*) containing the final solution.

**Raises**

- NoConvergence**  
When a solution was not found.

`scipy.optimize.linearminimize` (*F*, *xin*, *iter=None*, *alpha=None*, *verbose=False*, *max-iter=None*, *f\_tol=None*, *f\_rtol=None*, *x\_tol=None*, *x\_rtol=None*, *tol\_norm=None*, *line\_search='armijo'*, *callback=None*, *\*\*kw*)

Find a root of a function, using a scalar Jacobian approximation.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

- F** : function(x) -> f  
Function whose root to find; should take and return an array-like object.
- xin** : array\_like  
Initial guess for the solution
- alpha** : float, optional  
The Jacobian approximation is (-1/alpha).
- iter** : int, optional  
Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- verbose** : bool, optional  
Print status to stdout on every iteration.
- maxiter** : int, optional  
Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.
- f\_tol** : float, optional  
Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- f\_rtol** : float, optional  
Relative tolerance for the residual. If omitted, not used.

Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
- callback** : function, optional  
Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual.

**Returns**

- sol** : ndarray  
An array (of similar array type as *x0*) containing the final solution.

**Raises**

- NoConvergence**  
When a solution was not found.

`scipy.optimize.diagbroyden` (*F*, *xin*, *iter=None*, *alpha=None*, *verbose=False*, *maxiter=None*, *f\_tol=None*, *f\_rtol=None*, *x\_tol=None*, *x\_rtol=None*, *tol\_norm=None*, *line\_search='armijo'*, *callback=None*, *\*\*kw*)

Find a root of a function, using diagonal Broyden Jacobian approximation.

The Jacobian approximation is derived from previous iterations, by retaining only the diagonal of Broyden matrices.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

- F** : function(x) -> f  
Function whose root to find; should take and return an array-like object.
- xin** : array\_like  
Initial guess for the solution
- alpha** : float, optional  
Initial guess for the Jacobian is (-1/alpha).
- iter** : int, optional  
Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- verbose** : bool, optional  
Print status to stdout on every iteration.
- maxiter** : int, optional  
Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.
- f\_tol** : float, optional  
Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- f\_rtol** : float, optional  
Relative tolerance for the residual. If omitted, not used.
- x\_tol** : float, optional  
Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- x\_rtol** : float, optional  
Relative minimum step size. If omitted, not used.
- tol\_norm** : function(vector) -> scalar, optional  
Norm to use in convergence check. Default is the maximum norm.
- line\_search** : {None, 'armijo' (default), 'wolfe'}, optional  
Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
- callback** : function, optional  
Optional callback function. It is called on every iteration as `callback(x, f)` where  $x$  is the current solution and  $f$  the corresponding residual.

**Returns**

- sol** : ndarray  
An array (of similar array type as  $x0$ ) containing the final solution.

**Raises**

- NoConvergence**  
When a solution was not found.

*Additional information on the nonlinear solvers*

## 5.18.4 Linear Programming

General linear programming solver:

`linprog(c[, A_ub, b_ub, A_eq, b_eq, bounds, ...])`      Minimize a linear objective function subject to linear equality and inequality constraints.

`scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='simplex', callback=None, options=None)`

Minimize a linear objective function subject to linear equality and inequality constraints.

Linear Programming is intended to solve the following problem form:

```
Minimize:      c^T * x
Subject to:    A_ub * x <= b_ub
               A_eq * x == b_eq
```

**Parameters** **c** : array\_like

Coefficients of the linear objective function to be minimized.

**A\_ub** : array\_like, optional

2-D array which, when matrix-multiplied by *x*, gives the values of the upper-bound inequality constraints at *x*.

**b\_ub** : array\_like, optional

1-D array of values representing the upper-bound of each inequality constraint (row) in *A\_ub*.

**A\_eq** : array\_like, optional

2-D array which, when matrix-multiplied by *x*, gives the values of the equality constraints at *x*.

**b\_eq** : array\_like, optional

1-D array of values representing the RHS of each equality constraint (row) in *A\_eq*.

**bounds** : sequence, optional

(*min*, *max*) pairs for each element in *x*, defining the bounds on that parameter. Use *None* for one of *min* or *max* when there is no bound in that direction. By default bounds are (0, *None*) (non-negative) If a sequence containing a single tuple is provided, then *min* and *max* will be applied to all variables in the problem.

**method** : str, optional

Type of solver. 'simplex' and 'interior-point' are supported.

**callback** : callable, optional (simplex only)

If a callback function is provide, it will be called within each iteration of the simplex algorithm. The callback must have the signature `callback(xk, **kwargs)` where *xk* is the current solution vector and *kwargs* is a dictionary containing the following:

```
"tableau" : The current Simplex algorithm tableau
"nit" : The current iteration.
"pivot" : The pivot (row, column) used for the next_
↪iteration.
"phase" : Whether the algorithm is in Phase 1 or Phase_
↪2.
"basis" : The indices of the columns of the basic_
↪variables.
```

**options** : dict, optional

A dictionary of solver options. All methods accept the following generic options:

**maxiter** [int] Maximum number of iterations to perform.

**disp** [bool] Set to True to print convergence messages.

For method-specific options, see `show_options('linprog')`.

**Returns** A `scipy.optimize.OptimizeResult` consisting of the following fields:

<b><i>x</i></b>	[ndarray] The independent variable vector which optimizes the linear programming problem.
<b><i>fun</i></b>	[float] Value of the objective function.
<b><i>slack</i></b>	[ndarray] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, then the corresponding constraint is active.
<b><i>success</i></b>	[bool] Returns True if the algorithm succeeded in finding an optimal solution.
<b><i>status</i></b>	[int] An integer representing the exit status of the optimization:
	<pre>0 : Optimization terminated successfully 1 : Iteration limit reached 2 : Problem appears to be infeasible 3 : Problem appears to be unbounded</pre>
<b><i>nit</i></b>	[int] The number of iterations performed.
<b><i>message</i></b>	[str] A string descriptor of the exit status of the optimization.

**See also:**

**show\_options**

Additional options accepted by the solvers

**Notes**

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is *Simplex*. *Interior point* is also available.

Method *simplex* uses the simplex algorithm (as it relates to linear programming, NOT the Nelder-Mead simplex) [R201], [R202]. This algorithm should be reasonably reliable and fast for small problems.

New in version 0.15.0.

Method *interior-point* uses the primal-dual path following algorithm as outlined in [R204]. This algorithm is intended to provide a faster and more reliable alternative to *simplex*, especially for large, sparse problems. Note, however, that the solution returned may be slightly less accurate than that of the simplex method and may not correspond with a vertex of the polytope defined by the constraints.

**Examples**

Consider the following problem:

Minimize:  $f = -1 \cdot x[0] + 4 \cdot x[1]$   
**Subject to:**  $-3 \cdot x[0] + 1 \cdot x[1] \leq 6$

$$1 \cdot x[0] + 2 \cdot x[1] \leq 4$$

$$x[1] \geq -3$$

where:  $-\text{inf} \leq x[0] \leq \text{inf}$

This problem deviates from the standard linear programming problem. In standard form, linear programming problems assume the variables  $x$  are non-negative. Since the variables don’t have standard bounds where  $0 \leq x \leq \text{inf}$ , the bounds of the variables must be explicitly set.

There are two upper-bound constraints, which can be expressed as

$$\text{dot}(A\_ub, x) \leq b\_ub$$

<sup>10</sup> Andersen, Erling D., et al. Implementation of interior point methods for large scale linear programming. HEC/Universite de Geneve, 1996.

The input for this problem is as follows:

```

>>> c = [-1, 4]
>>> A = [[-3, 1], [1, 2]]
>>> b = [6, 4]
>>> x0_bounds = (None, None)
>>> x1_bounds = (-3, None)
>>> from scipy.optimize import linprog
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=(x0_bounds, x1_bounds),
...             options={"disp": True})
Optimization terminated successfully.
    Current function value: -22.000000
    Iterations: 1
>>> print(res)
fun: -22.0
message: 'Optimization terminated successfully.'
nit: 1
slack: array([ 39.,  0.])
status: 0
success: True
x: array([ 10., -3.])
    
```

Note the actual objective value is 11.428571. In this case we minimized the negative of the objective function.

The `linprog` function supports the following methods:

### `linprog(method='simplex')`

`scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='simplex', callback=None, options={'disp': False, 'bland': False, 'tol': 1e-12, 'maxiter': 1000})`

Solve the following linear programming problem via a two-phase simplex algorithm.:

```

minimize:    c^T * x

subject to:  A_ub * x <= b_ub
             A_eq * x == b_eq
    
```

**Parameters** `c`: array\_like

Coefficients of the linear objective function to be minimized.

`A_ub`: array\_like

2-D array which, when matrix-multiplied by `x`, gives the values of the upper-bound inequality constraints at `x`.

`b_ub`: array\_like

1-D array of values representing the upper-bound of each inequality constraint (row) in `A_ub`.

`A_eq`: array\_like

2-D array which, when matrix-multiplied by `x`, gives the values of the equality constraints at `x`.

`b_eq`: array\_like

1-D array of values representing the RHS of each equality constraint (row) in `A_eq`.

`bounds`: array\_like

The bounds for each independent variable in the solution, which can take one of three forms:

None : The default bounds, all variables are non-negative. (lb, ub) : If a 2-element sequence is provided, the same lower bound (lb) and upper bound (ub) will be applied to all variables.

`[(lb_0, ub_0), (lb_1, ub_1), ...]`  
 [If an n x 2 sequence is provided,] each variable `x_i` will be bounded by `lb[i]` and `ub[i]`.

Infinite bounds are specified using `-np.inf` (negative) or `np.inf` (positive).

**callback** : callable

If a callback function is provide, it will be called within each iteration of the simplex algorithm. The callback must have the signature `callback(xk, **kwargs)` where `xk` is the current solution vector and `kwargs` is a dictionary containing the following:

```
"tableau" : The current Simplex algorithm tableau
"nit" : The current iteration.
"pivot" : The pivot (row, column) used for the next_
           iteration.
"phase" : Whether the algorithm is in Phase 1 or Phase_
           2.
"bv" : A structured array containing a string_
        representation of each
```

**Returns** A `scipy.optimize.OptimizeResult` consisting of the following fields:

<b>x</b>	[ndarray] The independent variable vector which optimizes the linear programming problem.
<b>fun</b>	[float] Value of the objective function.
<b>slack</b>	[ndarray] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, then the corresponding constraint is active.
<b>success</b>	[bool] Returns True if the algorithm succeeded in finding an optimal solution.
<b>status</b>	[int] An integer representing the exit status of the optimization:

```
0 : Optimization terminated successfully
1 : Iteration limit reached
2 : Problem appears to be infeasible
3 : Problem appears to be unbounded
```

<b>nit</b>	[int] The number of iterations performed.
<b>message</b>	[str] A string descriptor of the exit status of the optimization.

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

**Options**

<b>maxiter</b> : int	The maximum number of iterations to perform.
<b>disp</b> : bool	If True, print exit status message to <code>sys.stdout</code>
<b>tol</b> : float	The tolerance which determines when a solution is “close enough” to zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve as an optimal solution.
<b>bland</b> : bool	

If True, use Bland's anti-cycling rule [3] to choose pivots to prevent cycling. If False, choose pivots which should lead to a converged solution more quickly. The latter method is subject to cycling (non-convergence) in rare instances.

### Examples

Consider the following problem:

Minimize:  $f = -1*x[0] + 4*x[1]$   
 Subject to:  $-3*x[0] + 1*x[1] \leq 6$

$$1*x[0] + 2*x[1] \leq 4$$

$$x[1] \geq -3$$

where:  $-\text{inf} \leq x[0] \leq \text{inf}$

This problem deviates from the standard linear programming problem. In standard form, linear programming problems assume the variables  $x$  are non-negative. Since the variables don't have standard bounds where  $0 \leq x \leq \text{inf}$ , the bounds of the variables must be explicitly set.

There are two upper-bound constraints, which can be expressed as

$$\text{dot}(A\_ub, x) \leq b\_ub$$

The input for this problem is as follows:

```
>>> from scipy.optimize import linprog
>>> c = [-1, 4]
>>> A = [[-3, 1], [1, 2]]
>>> b = [6, 4]
>>> x0_bnds = (None, None)
>>> x1_bnds = (-3, None)
>>> res = linprog(c, A, b, bounds=(x0_bnds, x1_bnds))
>>> print(res)
fun: -22.0
message: 'Optimization terminated successfully.'
nit: 1
slack: array([ 39.,  0.])
status: 0
success: True
x: array([ 10., -3.])
```

### linprog(method='interior-point')

`scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='interior-point', callback=None, options={'disp': False, 'sym_pos': True, 'alpha0': 0.99995, 'cholesky': None, 'tol': 1e-08, 'rr': True, 'ip': False, 'permc_spec': 'MMD_AT_PLUS_A', 'pc': True, 'beta': 0.1, 'lstsq': False, 'sparse': False, 'maxiter': 1000, 'presolve': True, '_sparse_presolve': False})`

Minimize a linear objective function subject to linear equality constraints, linear inequality constraints, and simple bounds using the interior point method of [R901].

Linear programming is intended to solve problems of the following form:

```

Minimize:    c^T * x

Subject to:  A_ub * x <= b_ub
            A_eq * x == b_eq
            bounds[i][0] < x_i < bounds[i][1]

```

**Parameters** **c** : array\_like

Coefficients of the linear objective function to be minimized.

**A\_ub** : array\_like, optional

2-D array which, when matrix-multiplied by *x*, gives the values of the upper-bound inequality constraints at *x*.

**b\_ub** : array\_like, optional

1-D array of values representing the upper-bound of each inequality constraint (row) in *A\_ub*.

**A\_eq** : array\_like, optional

2-D array which, when matrix-multiplied by *x*, gives the values of the equality constraints at *x*.

**b\_eq** : array\_like, optional

1-D array of values representing the right hand side of each equality constraint (row) in *A\_eq*.

**bounds** : sequence, optional

(*min*, *max*) pairs for each element in *x*, defining the bounds on that parameter. Use *None* for one of *min* or *max* when there is no bound in that direction. By default bounds are (0, *None*) (non-negative). If a sequence containing a single tuple is provided, then *min* and *max* will be applied to all variables in the problem.

**Returns** A `scipy.optimize.OptimizeResult` consisting of the following fields:

**x** [ndarray] The independent variable vector which optimizes the linear programming problem.

**fun** [float] The optimal value of the objective function

**con** [float] The residuals of the equality constraints (nominally zero).

**slack** [ndarray] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, then the corresponding constraint is active.

**success** [bool] Returns True if the algorithm succeeded in finding an optimal solution.

**status** [int] An integer representing the exit status of the optimization:

```

0 : Optimization terminated successfully
1 : Iteration limit reached
2 : Problem appears to be infeasible
3 : Problem appears to be unbounded
4 : Serious numerical difficulties_
   ↳ encountered

```

**nit**  
**message**

[int] The number of iterations performed.  
[str] A string descriptor of the exit status of the optimization.

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

**Options** **maxiter** : int (default = 1000)

The maximum number of iterations of the algorithm.

**disp** : bool (default = False)

Set to True if indicators of optimization status are to be printed to the console each iteration.

- tol** : float (default = 1e-8)  
Termination tolerance to be used for all termination criteria; see [R901] Section 4.5.
- alpha0** : float (default = 0.99995)  
The maximal step size for Mehrota's predictor-corrector search direction; see  $\beta_3$  of [R901] Table 8.1.
- beta** : float (default = 0.1)  
The desired reduction of the path parameter  $\mu$  (see [R903]) when Mehrota's predictor-corrector is not in use (uncommon).
- sparse** : bool (default = False)  
Set to `True` if the problem is to be treated as sparse after presolve. If either `A_eq` or `A_ub` is a sparse matrix, this option will automatically be set `True`, and the problem will be treated as sparse even during presolve. If your constraint matrices contain mostly zeros and the problem is not very small (less than about 100 constraints or variables), consider setting `True` or providing `A_eq` and `A_ub` as sparse matrices.
- lstsq** : bool (default = False)  
Set to `True` if the problem is expected to be very poorly conditioned. This should always be left `False` unless severe numerical difficulties are encountered. Leave this at the default unless you receive a warning message suggesting otherwise.
- sym\_pos** : bool (default = True)  
Leave `True` if the problem is expected to yield a well conditioned symmetric positive definite normal equation matrix (almost always). Leave this at the default unless you receive a warning message suggesting otherwise.
- cholesky** : bool (default = True)  
Set to `True` if the normal equations are to be solved by explicit Cholesky decomposition followed by explicit forward/backward substitution. This is typically faster for moderate, dense problems that are numerically well-behaved.
- pc** : bool (default = True)  
Leave `True` if the predictor-corrector method of Mehrota is to be used. This is almost always (if not always) beneficial.
- ip** : bool (default = False)  
Set to `True` if the improved initial point suggestion due to [R901] Section 4.3 is desired. Whether this is beneficial or not depends on the problem.
- presolve** : bool (default = True)  
Leave `True` if presolve routine should be run. The presolve routine is almost always useful because it can detect trivial infeasibilities and unbound-ness, eliminate fixed variables, and remove redundancies. One circumstance in which it might be turned off (set `False`) is when it detects that the problem is trivially unbounded; it is possible that that the problem is truly infeasible but this has not been detected.
- rr** : bool (default = True)  
Default `True` attempts to eliminate any redundant rows in `A_eq`. Set `False` if `A_eq` is known to be of full row rank, or if you are looking for a potential speedup (at the expense of reliability).
- permc\_spec** : str (default = 'MMD\_AT\_PLUS\_A')  
(Has effect only with `sparse = True`, `lstsq = False`, `sym_pos = True`.) A matrix is factorized in each iteration of the algorithm. This option specifies how to permute the columns of the matrix for sparsity preservation. Acceptable values are:
- `NATURAL`: natural ordering.

- MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
- MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T + A$ .
- COLAMD: approximate minimum degree column ordering.

This option can impact the convergence of the interior point algorithm; test different values to determine which performs best for your problem. For more information, refer to `scipy.sparse.linalg.splu`.

### Notes

This method implements the algorithm outlined in [R901] with ideas from [R905] and a structure inspired by the simpler methods of [R903] and [R904].

First, a presolve procedure based on [R905] attempts to identify trivial infeasibilities, trivial unboundedness, and potential problem simplifications. Specifically, it checks for:

- rows of zeros in `A_eq` or `A_ub`, representing trivial constraints;
- columns of zeros in `A_eq` and `A_ub`, representing unconstrained variables;
- column singletons in `A_eq`, representing fixed variables; and
- column singletons in `A_ub`, representing simple bounds.

If presolve reveals that the problem is unbounded (e.g. an unconstrained and unbounded variable has negative cost) or infeasible (e.g. a row of zeros in `A_eq` corresponds with a nonzero in `b_eq`), the solver terminates with the appropriate status code. Note that presolve terminates as soon as any sign of unboundedness is detected; consequently, a problem may be reported as unbounded when in reality the problem is infeasible (but infeasibility has not been detected yet). Therefore, if the output message states that unboundedness is detected in presolve and it is necessary to know whether the problem is actually infeasible, set option `presolve=False`.

If neither infeasibility nor unboundedness are detected in a single pass of the presolve check, bounds are tightened where possible and fixed variables are removed from the problem. Then, linearly dependent rows of the `A_eq` matrix are removed, (unless they represent an infeasibility) to avoid numerical difficulties in the primary solve routine. Note that rows that are nearly linearly dependent (within a prescribed tolerance) may also be removed, which can change the optimal solution in rare cases. If this is a concern, eliminate redundancy from your problem formulation and run with option `rr=False` or `presolve=False`.

Several potential improvements can be made here: additional presolve checks outlined in [R905] should be implemented, the presolve routine should be run multiple times (until no further simplifications can be made), and more of the efficiency improvements from [R902] should be implemented in the redundancy removal routines.

After presolve, the problem is transformed to standard form by converting the (tightened) simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables.

The primal-dual path following method begins with initial ‘guesses’ of the primal and dual variables of the standard form problem and iteratively attempts to solve the (nonlinear) Karush-Kuhn-Tucker conditions for the problem with a gradually reduced logarithmic barrier term added to the objective. This particular implementation uses a homogeneous self-dual formulation, which provides certificates of infeasibility or unboundedness where applicable.

The default initial point for the primal and dual variables is that defined in [R901] Section 4.4 Equation 8.22. Optionally (by setting initial point option `ip=True`), an alternate (potentially improved) starting point can be calculated according to the additional recommendations of [R901] Section 4.4.

A search direction is calculated using the predictor-corrector method (single correction) proposed by Mehrotra and detailed in [R901] Section 4.1. (A potential improvement would be to implement the method of multiple corrections described in [R901] Section 4.2.) In practice, this is accomplished by solving the normal equations, [R901] Section 5.1 Equations 8.31 and 8.32, derived from the Newton equations [R901] Section 5 Equations 8.25 (compare to [R901] Section 4 Equations 8.6-8.8). The advantage of solving the normal equations rather than 8.25 directly is that the matrices involved are symmetric positive definite, so Cholesky decomposition can be used rather than the more expensive LU factorization.

With the default `cholesky=True`, this is accomplished using `scipy.linalg.cho_factor` followed by forward/backward substitutions via `scipy.linalg.cho_solve`. With `cholesky=False` and `sym_pos=True`, Cholesky decomposition is performed instead by `scipy.linalg.solve`. Based on speed tests, this also appears to retain the Cholesky decomposition of the matrix for later use, which is beneficial as the same system is solved four times with different right hand sides in each iteration of the algorithm.

In problems with redundancy (e.g. if `presolve` is turned off with option `presolve=False`) or if the matrices become ill-conditioned (e.g. as the solution is approached and some decision variables approach zero), Cholesky decomposition can fail. Should this occur, successively more robust solvers (`scipy.linalg.solve` with `sym_pos=False` then `scipy.linalg.lstsq`) are tried, at the cost of computational efficiency. These solvers can be used from the outset by setting the options `sym_pos=False` and `lstsq=True`, respectively.

Note that with the option `sparse=True`, the normal equations are solved using `scipy.sparse.linalg.spsolve`. Unfortunately, this uses the more expensive LU decomposition from the outset, but for large, sparse problems, the use of sparse linear algebra techniques improves the solve speed despite the use of LU rather than Cholesky decomposition. A simple improvement would be to use the sparse Cholesky decomposition of CHOLMOD via `scikit-sparse` when available.

Other potential improvements for combatting issues associated with dense columns in otherwise sparse problems are outlined in [R901] Section 5.3 and [R907] Section 4.1-4.2; the latter also discusses the alleviation of accuracy issues associated with the substitution approach to free variables.

After calculating the search direction, the maximum possible step size that does not activate the non-negativity constraints is calculated, and the smaller of this step size and unity is applied (as in [R901] Section 4.1.) [R901] Section 4.3 suggests improvements for choosing the step size.

The new point is tested according to the termination conditions of [R901] Section 4.5. The same tolerance, which can be set using the `tol` option, is used for all checks. (A potential improvement would be to expose the different tolerances to be set independently.) If optimality, unboundedness, or infeasibility is detected, the solve procedure terminates; otherwise it repeats.

If optimality is achieved, a `postsolve` procedure undoes transformations associated with `presolve` and converting to standard form. It then calculates the residuals (equality constraint violations, which should be very small) and slacks (difference between the left and right hand sides of the upper bound constraints) of the original problem, which are returned with the solution in an `OptimizeResult` object.

[R901], [R902], [R903], [R904], [R905], [R906], [R907]

The simplex method supports callback functions, such as:

<code>linprog_verbose_callback(xk, **kwargs)</code>	A sample callback function demonstrating the linprog callback interface.
---	--

---

`scipy.optimize.linprog_verbose_callback(xk, **kwargs)`

A sample callback function demonstrating the linprog callback interface. This callback produces detailed output to `sys.stdout` before each iteration and after the final iteration of the simplex algorithm.

**Parameters**

- xk** : array\_like  
The current solution vector.
- \*\*kwargs** : dict  
A dictionary containing the following parameters:
  - tableau** [array\_like] The current tableau of the simplex algorithm. Its structure is defined in `._solve_simplex`.
  - phase** [int] The current phase of the simplex algorithm (1 or 2)
  - nit** [int] The current iteration number.
  - pivot** [tuple(int, int)] The index of the tableau selected as the next pivot, or nan if no pivot exists

**basis** [array(int)] A list of the current basic variables. Each element contains the name of a basic variable and its value.

**complete** [bool] True if the simplex algorithm has completed (and this is the final call to callback), otherwise False.

Assignment problems:

---

`linear_sum_assignment(cost_matrix)` Solve the linear sum assignment problem.

---

`scipy.optimize.linear_sum_assignment(cost_matrix)`  
Solve the linear sum assignment problem.

The linear sum assignment problem is also known as minimum weight matching in bipartite graphs. A problem instance is described by a matrix  $C$ , where each  $C[i,j]$  is the cost of matching vertex  $i$  of the first partite set (a “worker”) and vertex  $j$  of the second set (a “job”). The goal is to find a complete assignment of workers to jobs of minimal cost.

Formally, let  $X$  be a boolean matrix where  $X[i,j] = 1$  iff row  $i$  is assigned to column  $j$ . Then the optimal assignment has cost

$$\min \sum_i \sum_j C_{i,j} X_{i,j}$$

s.t. each row is assignment to at most one column, and each column to at most one row.

This function can also solve a generalization of the classic assignment problem where the cost matrix is rectangular. If it has more rows than columns, then not every row needs to be assigned to a column, and vice versa.

The method used is the Hungarian algorithm, also known as the Munkres or Kuhn-Munkres algorithm.

**Parameters** **cost\_matrix**: array  
The cost matrix of the bipartite graph.

**Returns** **row\_ind, col\_ind**: array  
An array of row indices and one of corresponding column indices giving the optimal assignment. The cost of the assignment can be computed as `cost_matrix[row_ind, col_ind].sum()`. The row indices will be sorted; in the case of a square cost matrix they will be equal to `numpy.arange(cost_matrix.shape[0])`.

```

### 5.18.5 Utilities

<code>approx_fprime(xk, f, epsilon, *args)</code>	Finite-difference approximation of the gradient of a scalar function.
<code>bracket(func[, xa, xb, args, grow_limit, ...])</code>	Bracket the minimum of the function.
<code>check_grad(func, grad, x0, *args, **kwargs)</code>	Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.
<code>line_search(f, myfprime, xk, pk[, gfk, ...])</code>	Find alpha that satisfies strong Wolfe conditions.
<code>show_options([solver, method, disp])</code>	Show documentation for additional options of optimization solvers.
<code>LbfgsInvHessProduct(sk, yk)</code>	Linear operator for the L-BFGS approximate inverse Hessian.

`scipy.optimize.approx_fprime(xk, f, epsilon, *args)`

Finite-difference approximation of the gradient of a scalar function.

**Parameters** `xk` : array\_like

The coordinate vector at which to determine the gradient of  $f$ .

`f` : callable

The function of which to determine the gradient (partial derivatives). Should take  $xk$  as first argument, other arguments to  $f$  can be supplied in `*args`. Should return a scalar, the value of the function at  $xk$ .

`epsilon` : array\_like

Increment to  $xk$  to use for determining the function gradient. If a scalar, uses the same finite difference delta for all partial derivatives. If an array, should contain one value per element of  $xk$ .

`*args` : args, optional

Any other arguments that are to be passed to  $f$ .

**Returns**

`grad` : ndarray

The partial derivatives of  $f$  to  $xk$ .

**See also:**

`check_grad` Check correctness of gradient function against `approx_fprime`.

**Notes**

The function gradient is determined by the forward finite difference formula:

$$f'[i] = \frac{f(xk[i] + \epsilon[i]) - f(xk[i])}{\epsilon[i]}$$

The main use of `approx_fprime` is in scalar function optimizers like `fmin_bfgs`, to determine numerically the Jacobian of a function.

**Examples**

```
>>> from scipy import optimize
>>> def func(x, c0, c1):
...     "Coordinate vector `x` should be an array of size two."
...     return c0 * x[0]**2 + c1*x[1]**2
```

```
>>> x = np.ones(2)
>>> c0, c1 = (1, 200)
>>> eps = np.sqrt(np.finfo(float).eps)
>>> optimize.approx_fprime(x, func, [eps, np.sqrt(200) * eps], c0, c1)
array([ 2.          , 400.00004198])
```

`scipy.optimize.bracket` (*func*, *xa=0.0*, *xb=1.0*, *args=()*, *grow\_limit=110.0*, *maxiter=1000*)

Bracket the minimum of the function.

Given a function and distinct initial points, search in the downhill direction (as defined by the initial points) and return new points *xa*, *xb*, *xc* that bracket the minimum of the function  $f(xa) > f(xb) < f(xc)$ . It doesn't always mean that obtained solution will satisfy  $xa \leq x \leq xb$

**Parameters**

- func** : callable  $f(x, *args)$   
Objective function to minimize.
- xa, xb** : float, optional  
Bracketing interval. Defaults *xa* to 0.0, and *xb* to 1.0.
- args** : tuple, optional  
Additional arguments (if present), passed to *func*.
- grow\_limit** : float, optional  
Maximum grow limit. Defaults to 110.0
- maxiter** : int, optional  
Maximum number of iterations to perform. Defaults to 1000.

**Returns**

- xa, xb, xc** : float  
Bracket.
- fa, fb, fc** : float  
Objective function values in bracket.
- funcalls** : int  
Number of function evaluations made.

`scipy.optimize.check_grad` (*func*, *grad*, *x0*, *\*args*, *\*\*kwargs*)

Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.

**Parameters**

- func** : callable  $func(x0, *args)$   
Function whose derivative is to be checked.
- grad** : callable  $grad(x0, *args)$   
Gradient of *func*.
- x0** : ndarray  
Points to check *grad* against forward difference approximation of *grad* using *func*.
- args** : *\*args*, optional  
Extra arguments passed to *func* and *grad*.
- epsilon** : float, optional  
Step size used for the finite difference approximation. It defaults to  $\sqrt{\text{numpy.finfo(float).eps}}$ , which is approximately 1.49e-08.

**Returns**

- err** : float  
The square root of the sum of squares (i.e. the 2-norm) of the difference between  $grad(x0, *args)$  and the finite difference approximation of *grad* using *func* at the points *x0*.

See also:

`approx_fprime`

**Examples**

```
>>> def func(x):
...     return x[0]**2 - 0.5 * x[1]**3
>>> def grad(x):
...     return [2 * x[0], -1.5 * x[1]**2]
>>> from scipy.optimize import check_grad
>>> check_grad(func, grad, [1.5, -1.5])
2.9802322387695312e-08
```

`scipy.optimize.line_search` (*f*, *myfprime*, *xk*, *pk*, *gfk=None*, *old\_fval=None*, *old\_old\_fval=None*, *args=()*, *c1=0.0001*, *c2=0.9*, *amax=None*, *extra\_condition=None*, *maxiter=10*)

Find alpha that satisfies strong Wolfe conditions.

- Parameters**
- f**: callable *f*(*x*,\**args*)  
Objective function.
  - myfprime**: callable *f'*(*x*,\**args*)  
Objective function gradient.
  - xk**: ndarray  
Starting point.
  - pk**: ndarray  
Search direction.
  - gfk**: ndarray, optional  
Gradient value for *x*=*xk* (*xk* being the current parameter estimate). Will be recomputed if omitted.
  - old\_fval**: float, optional  
Function value for *x*=*xk*. Will be recomputed if omitted.
  - old\_old\_fval**: float, optional  
Function value for the point preceding *x*=*xk*
  - args**: tuple, optional  
Additional arguments passed to objective function.
  - c1**: float, optional  
Parameter for Armijo condition rule.
  - c2**: float, optional  
Parameter for curvature condition rule.
  - amax**: float, optional  
Maximum step size
  - extra\_condition**: callable, optional  
A callable of the form `extra_condition(alpha, x, f, g)` returning a boolean. Arguments are the proposed step *alpha* and the corresponding *x*, *f* and *g* values. The line search accepts the value of *alpha* only if this callable returns `True`. If the callable returns `False` for the step length, the algorithm will continue with new iterates. The callable is only called for iterates satisfying the strong Wolfe conditions.
  - maxiter**: int, optional  
Maximum number of iterations to perform
- Returns**
- alpha**: float or None  
Alpha for which  $x_{new} = x_0 + alpha * pk$ , or None if the line search algorithm did not converge.
  - fc**: int  
Number of function evaluations made.
  - gc**: int

Number of gradient evaluations made.

**new\_fval** : float or None  
New function value  $f(x_{\text{new}}) = f(x_0 + \alpha * pk)$ , or None if the line search algorithm did not converge.

**old\_fval** : float  
Old function value  $f(x_0)$ .

**new\_slope** : float or None  
The local slope along the search direction at the new value  $\langle \text{myfprime}(x_{\text{new}}), pk \rangle$ , or None if the line search algorithm did not converge.

**Notes**

Uses the line search algorithm to enforce strong Wolfe conditions. See Wright and Nocedal, ‘Numerical Optimization’, 1999, pg. 59-60.

For the zoom phase it uses an algorithm by [...].

`scipy.optimize.show_options(solver=None, method=None, disp=True)`

Show documentation for additional options of optimization solvers.

These are method-specific options that can be supplied through the `options` dict.

<b>Parameters</b>	<b>solver</b> : str	Type of optimization solver. One of ‘minimize’, ‘minimize_scalar’, ‘root’, or ‘linprog’.
	<b>method</b> : str, optional	If not given, shows all methods of the specified solver. Otherwise, show only the options for the specified method. Valid values corresponds to methods’ names of respective solver (e.g. ‘BFGS’ for ‘minimize’).
	<b>disp</b> : bool, optional	Whether to print the result rather than returning it.
<b>Returns</b>	text	Either None (for <code>disp=False</code> ) or the text string ( <code>disp=True</code> )

**Notes**

The solver-specific methods are:

`scipy.optimize.minimize`

- Nelder-Mead
- Powell
- CG
- BFGS
- Newton-CG
- L-BFGS-B
- TNC
- COBYLA
- SLSQP
- dogleg
- trust-ncg

`scipy.optimize.root`

- hybr
- lm
- broyden1
- broyden2
- anderson
- linearmixing

- diagbroyden*
- excitingmixing*
- krylov*
- df-sane*
- scipy.optimize.minimize\_scalar*
  - brent*
  - golden*
  - bounded*
- scipy.optimize.linprog*
  - simplex*
  - interior-point*

**class** `scipy.optimize.LbfgsInvHessProduct` (*sk*, *yk*)  
 Linear operator for the L-BFGS approximate inverse Hessian.

This operator computes the product of a vector with the approximate inverse of the Hessian of the objective function, using the L-BFGS limited memory approximation to the inverse Hessian, accumulated during the optimization.

Objects of this class implement the `scipy.sparse.linalg.LinearOperator` interface.

- Parameters**
- sk** : array\_like, shape=(*n\_corr*, *n*)  
 Array of *n\_corr* most recent updates to the solution vector. (See [1]).
  - yk** : array\_like, shape=(*n\_corr*, *n*)  
 Array of *n\_corr* most recent updates to the gradient. (See [1]).

**References**

[R187]

**Attributes**

<i>H</i>	Hermitian adjoint.
<i>T</i>	Transpose this linear operator.

`LbfgsInvHessProduct.H`

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated `self.H` instead of `self.adjoint()`.

- Returns** **A\_H** : LinearOperator  
 Hermitian adjoint of self.

`LbfgsInvHessProduct.T`

Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated `self.T` instead of `self.transpose()`.

**Methods**

<code>__call__(x)</code>	
<code>adjoint()</code>	Hermitian adjoint.
<code>dot(x)</code>	Matrix-matrix or matrix-vector multiplication.

Continued on next page

Table 5.134 – continued from previous page

<code>matmat(X)</code>	Matrix-matrix multiplication.
<code>matvec(x)</code>	Matrix-vector multiplication.
<code>rmatvec(x)</code>	Adjoint matrix-vector multiplication.
<code>todense()</code>	Return a dense array representation of this operator.
<code>transpose()</code>	Transpose this linear operator.

`LbfgsInvHessProduct.__call__(x)`

`LbfgsInvHessProduct.adjoint()`

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

**Returns** **A\_H** : LinearOperator  
Hermitian adjoint of self.

`LbfgsInvHessProduct.dot(x)`

Matrix-matrix or matrix-vector multiplication.

**Parameters** **x** : array\_like

**Returns** **Ax** : array 1-d or 2-d array, representing a vector or matrix.

1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

`LbfgsInvHessProduct.matmat(X)`

Matrix-matrix multiplication.

Performs the operation  $y=A*X$  where A is an MxN linear operator and X dense N\*K matrix or ndarray.

**Parameters** **X** : {matrix, ndarray}

**Returns** **Y** : {matrix, ndarray} An array with shape (N,K).

A matrix or ndarray with shape (M,K) depending on the type of the X argument.

#### Notes

This matmat wraps any user-specified matmat routine or overridden `_matmat` method to ensure that y has the correct type.

`LbfgsInvHessProduct.matvec(x)`

Matrix-vector multiplication.

Performs the operation  $y=A*x$  where A is an MxN linear operator and x is a column vector or 1-d array.

**Parameters** **x** : {matrix, ndarray}

**Returns** **y** : {matrix, ndarray} An array with shape (N,) or (N,1).

A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.

#### Notes

This matvec wraps the user-specified matvec routine or overridden `_matvec` method to ensure that y has the correct shape and type.

`LbfgsInvHessProduct.rmatvec(x)`

Adjoint matrix-vector multiplication.

Performs the operation  $y = A^H * x$  where  $A$  is an  $M \times N$  linear operator and  $x$  is a column vector or 1-d array.

**Parameters** `x` : {matrix, ndarray}

**Returns** `y` : {matrix, ndarray} An array with shape (M,) or (M,1).

A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the `x` argument.

**Notes**

This `rmatvec` wraps the user-specified `rmatvec` routine or overridden `_rmatvec` method to ensure that `y` has the correct shape and type.

`LbfgsInvHessProduct.todense()`

Return a dense array representation of this operator.

**Returns** `arr` : ndarray, shape=(n, n)

An array with the same shape and containing the same data represented by this *LinearOperator*.

`LbfgsInvHessProduct.transpose()`

Transpose this linear operator.

Returns a *LinearOperator* that represents the transpose of this one. Can be abbreviated `self.T` instead of `self.transpose()`.

## 5.19 Nonlinear solvers

This is a collection of general-purpose nonlinear multidimensional solvers. These solvers find  $x$  for which  $F(x) = 0$ . Both  $x$  and  $F$  can be multidimensional.

### 5.19.1 Routines

Large-scale nonlinear solvers:

<code>newton_krylov(F, xin[, iter, rdiff, method, ...])</code>	Find a root of a function, using Krylov approximation for inverse Jacobian.
<code>anderson(F, xin[, iter, alpha, w0, M, ...])</code>	Find a root of a function, using (extended) Anderson mixing.

General nonlinear solvers:

<code>broyden1(F, xin[, iter, alpha, ...])</code>	Find a root of a function, using Broyden's first Jacobian approximation.
<code>broyden2(F, xin[, iter, alpha, ...])</code>	Find a root of a function, using Broyden's second Jacobian approximation.

Simple iterations:

<code>excitingmixing(F, xin[, iter, alpha, ...])</code>	Find a root of a function, using a tuned diagonal Jacobian approximation.
<code>linearmixing(F, xin[, iter, alpha, verbose, ...])</code>	Find a root of a function, using a scalar Jacobian approximation.
<code>diagbroyden(F, xin[, iter, alpha, verbose, ...])</code>	Find a root of a function, using diagonal Broyden Jacobian approximation.

## 5.19.2 Examples

### Small problem

```
>>> def F(x):
...     return np.cos(x) + x[::-1] - [1, 2, 3, 4]
>>> import scipy.optimize
>>> x = scipy.optimize.broyden1(F, [1,1,1,1], f_tol=1e-14)
>>> x
array([ 4.04674914,  3.91158389,  2.71791677,  1.61756251])
>>> np.cos(x) + x[::-1]
array([ 1.,  2.,  3.,  4.])
```

### Large problem

Suppose that we needed to solve the following integrodifferential equation on the square  $[0, 1] \times [0, 1]$ :

$$\nabla^2 P = 10 \left( \int_0^1 \int_0^1 \cosh(P) dx dy \right)^2$$

with  $P(x, 1) = 1$  and  $P = 0$  elsewhere on the boundary of the square.

The solution can be found using the `newton_krylov` solver:

```
import numpy as np
from scipy.optimize import newton_krylov
from numpy import cosh, zeros_like, mgrid, zeros

# parameters
nx, ny = 75, 75
hx, hy = 1./(nx-1), 1./(ny-1)

P_left, P_right = 0, 0
P_top, P_bottom = 1, 0

def residual(P):
    d2x = zeros_like(P)
    d2y = zeros_like(P)

    d2x[1:-1] = (P[2:] - 2*P[1:-1] + P[:-2]) / hx/hx
    d2x[0] = (P[1] - 2*P[0] + P_left) / hx/hx
    d2x[-1] = (P_right - 2*P[-1] + P[-2]) / hx/hx

    d2y[:,1:-1] = (P[:,2:] - 2*P[:,1:-1] + P[:, :-2]) / hy/hy
    d2y[:,0] = (P[:,1] - 2*P[:,0] + P_bottom) / hy/hy
    d2y[:, -1] = (P_top - 2*P[:, -1] + P[:, -2]) / hy/hy

    return d2x + d2y - 10*cosh(P).mean()**2
```

```
# solve
guess = zeros((nx, ny), float)
sol = newton_krylov(residual, guess, method='lgmres', verbose=1)
print('Residual: %g' % abs(residual(sol)).max())

# visualize
import matplotlib.pyplot as plt
x, y = mgrid[0:1:(nx*1j), 0:1:(ny*1j)]
plt.pcolor(x, y, sol)
plt.colorbar()
plt.show()
```

## 5.20 Signal processing (`scipy.signal`)

### 5.20.1 Convolution

<code>convolve(in1, in2[, mode, method])</code>	Convolve two N-dimensional arrays.
<code>correlate(in1, in2[, mode, method])</code>	Cross-correlate two N-dimensional arrays.
<code>fftconvolve(in1, in2[, mode])</code>	Convolve two N-dimensional arrays using FFT.
<code>convolve2d(in1, in2[, mode, boundary, fillvalue])</code>	Convolve two 2-dimensional arrays.
<code>correlate2d(in1, in2[, mode, boundary, ...])</code>	Cross-correlate two 2-dimensional arrays.
<code>sepfir2d((input, hrow, hcol) -&gt; output)</code>	Description:
<code>choose_conv_method(in1, in2[, mode, measure])</code>	Find the fastest convolution/correlation method.

`scipy.signal.convolve` (*in1*, *in2*, *mode*='full', *method*='auto')

Convolve two N-dimensional arrays.

Convolve *in1* and *in2*, with the output size determined by the *mode* argument.

**Parameters** **in1** : array\_like  
First input.

**in2** : array\_like  
Second input. Should have the same number of dimensions as *in1*.

**mode** : str { 'full', 'valid', 'same' }, optional  
 A string indicating the size of the output:

- full** The output is the full discrete linear convolution of the inputs. (Default)
- valid** The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.
- same** The output is the same size as *in1*, centered with respect to the 'full' output.

**method** : str { 'auto', 'direct', 'fft' }, optional  
 A string indicating which method to use to calculate the convolution.

- direct** The convolution is determined directly from sums, the definition of convolution.
- fft** The Fourier Transform is used to perform the convolution by calling `fftconvolve`.
- auto** Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See Notes for more detail.

**Returns** **convolve** : array  
 An N-dimensional array containing a subset of the discrete linear convolution of *in1* with *in2*.  
 New in version 0.19.0.

**See also:**`numpy.polymul`

performs polynomial multiplication (same operation, but also accepts poly1d objects)

`choose_conv_method`

chooses the fastest appropriate convolution method

`fftconvolve`**Notes**

By default, `convolve` and `correlate` use `method='auto'`, which calls `choose_conv_method` to choose the fastest method using pre-computed values (`choose_conv_method` can also measure real-world timing with a keyword argument). Because `fftconvolve` relies on floating point numbers, there are certain constraints that may force `method=direct` (more detail in `choose_conv_method` docstring).

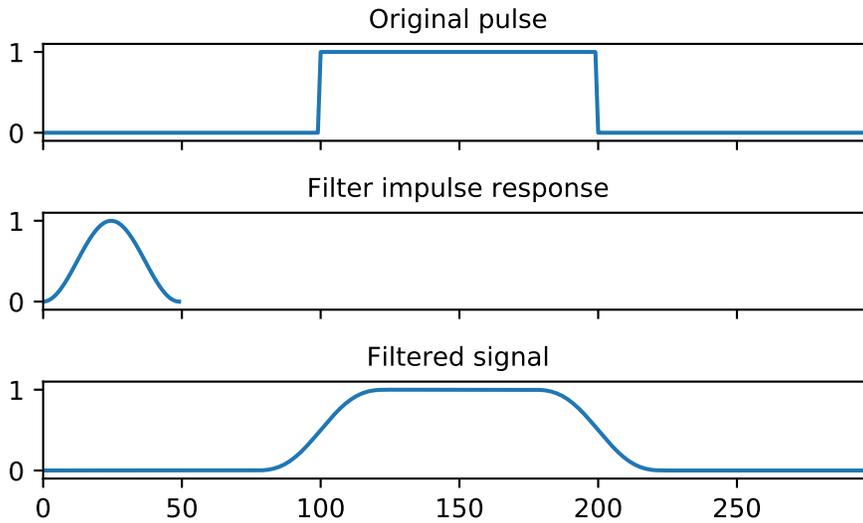

**Examples**

Smooth a square pulse using a Hann window:

```
>>> from scipy import signal
>>> sig = np.repeat([0., 1., 0.], 100)
>>> win = signal.hann(50)
>>> filtered = signal.convolve(sig, win, mode='same') / sum(win)
```

```
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_win, ax_filt) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('Original pulse')
>>> ax_orig.margins(0, 0.1)
>>> ax_win.plot(win)
>>> ax_win.set_title('Filter impulse response')
>>> ax_win.margins(0, 0.1)
>>> ax_filt.plot(filtered)
>>> ax_filt.set_title('Filtered signal')
>>> ax_filt.margins(0, 0.1)
```

```
>>> fig.tight_layout()
>>> fig.show()
```

`scipy.signal.correlate` (*in1*, *in2*, *mode*='full', *method*='auto')

Cross-correlate two N-dimensional arrays.

Cross-correlate *in1* and *in2*, with the output size determined by the *mode* argument.

**Parameters**

- in1** : array\_like  
First input.
- in2** : array\_like  
Second input. Should have the same number of dimensions as *in1*.
- mode** : str {'full', 'valid', 'same'}, optional  
A string indicating the size of the output:
  - full** : The output is the full discrete linear cross-correlation of the inputs. (Default)
  - valid** : The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.
  - same** : The output is the same size as *in1*, centered with respect to the 'full' output.
- method** : str {'auto', 'direct', 'fft'}, optional  
A string indicating which method to use to calculate the correlation.
  - direct** : The correlation is determined directly from sums, the definition of correlation.
  - fft** : The Fast Fourier Transform is used to perform the correlation more quickly (only available for numerical arrays.)
  - auto** : Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See *convolve* Notes for more detail.

**Returns**

- correlate** : array  
An N-dimensional array containing a subset of the discrete linear cross-correlation of *in1* with *in2*.

New in version 0.19.0.

See also:

`choose_conv_method`

contains more documentation on *method*.

**Notes**

The correlation  $z$  of two  $d$ -dimensional arrays  $x$  and  $y$  is defined as:

$$z[\dots, k, \dots] = \text{sum}[\dots, i_1, \dots] x[\dots, i_1, \dots] * \text{conj}(y[\dots, i_1 - k, \dots])$$

This way, if  $x$  and  $y$  are 1-D arrays and  $z = \text{correlate}(x, y, \text{'full'})$  then

$$z[k] = (x * y)(k - N + 1) = \sum_{l=0}^{|x|-1} x_l y_{l-k+N-1}^*$$

for  $k = 0, 1, \dots, |x| + |y| - 2$

where  $|x|$  is the length of  $x$ ,  $N = \max(|x|, |y|)$ , and  $y_m$  is 0 when  $m$  is outside the range of  $y$ .

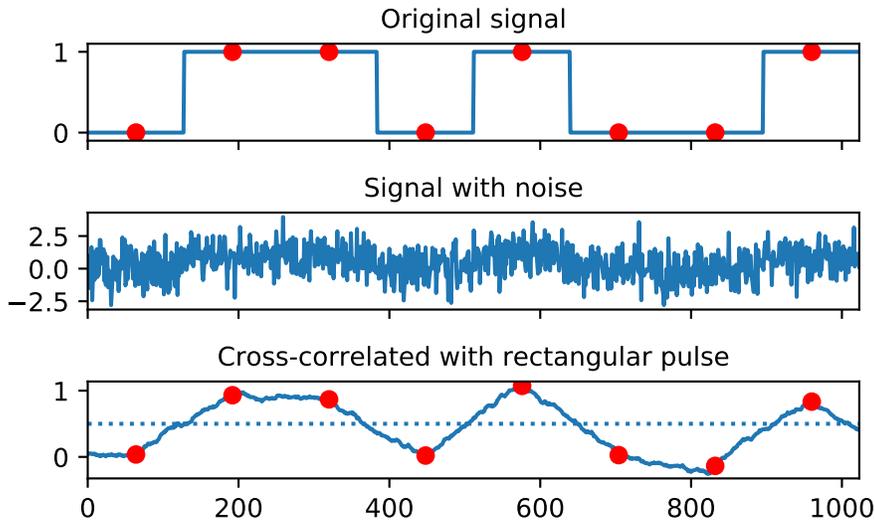

`method='fft'` only works for numerical arrays as it relies on `fftconvolve`. In certain cases (i.e., arrays of objects or when rounding integers can lose precision), `method='direct'` is always used.

**Examples**

Implement a matched filter using cross-correlation, to recover a signal that has passed through a noisy channel.

```
>>> from scipy import signal
>>> sig = np.repeat([0., 1., 1., 0., 1., 0., 0., 1.], 128)
>>> sig_noise = sig + np.random.randn(len(sig))
>>> corr = signal.correlate(sig_noise, np.ones(128), mode='same') / 128
```

```
>>> import matplotlib.pyplot as plt
>>> clock = np.arange(64, len(sig), 128)
>>> fig, (ax_orig, ax_noise, ax_corr) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.plot(clock, sig[clock], 'ro')
>>> ax_orig.set_title('Original signal')
>>> ax_noise.plot(sig_noise)
>>> ax_noise.set_title('Signal with noise')
>>> ax_corr.plot(corr)
>>> ax_corr.plot(clock, corr[clock], 'ro')
>>> ax_corr.axhline(0.5, ls=':')
>>> ax_corr.set_title('Cross-correlated with rectangular pulse')
>>> ax_orig.margins(0, 0.1)
>>> fig.tight_layout()
>>> fig.show()
```

`scipy.signal.fftconvolve` (*in1*, *in2*, *mode*='full')

Convolve two N-dimensional arrays using FFT.

Convolve *in1* and *in2* using the fast Fourier transform method, with the output size determined by the *mode* argument.

This is generally much faster than `convolve` for large arrays ( $n > \sim 500$ ), but can be slower when only a few output values are needed, and can only output float arrays (int or object array inputs will be cast to float).

As of v0.19, `convolve` automatically chooses this method or the direct method based on an estimation of which is faster.

**Parameters**

**in1** : array\_like  
First input.

**in2** : array\_like  
Second input. Should have the same number of dimensions as *in1*. If operating in 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.

**mode** : str {'full', 'valid', 'same'}, optional  
A string indicating the size of the output:

- full**        The output is the full discrete linear convolution of the inputs. (Default)
- valid**        The output consists only of those elements that do not rely on the zero-padding.
- same**         The output is the same size as *in1*, centered with respect to the 'full' output.

**Returns**

**out** : array  
An N-dimensional array containing a subset of the discrete linear convolution of *in1* with *in2*.

### Examples

Autocorrelation of white noise is an impulse.

```
>>> from scipy import signal
>>> sig = np.random.randn(1000)
>>> autocorr = signal.fftconvolve(sig, sig[::-1], mode='full')
```

```

>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag) = plt.subplots(2, 1)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('White noise')
>>> ax_mag.plot(np.arange(-len(sig)+1, len(sig)), autocorr)
>>> ax_mag.set_title('Autocorrelation')
>>> fig.tight_layout()
>>> fig.show()

```

Gaussian blur implemented using FFT convolution. Notice the dark borders around the image, due to the zero-padding beyond its boundaries. The `convolve2d` function allows for other types of image boundaries, but is far slower.

```

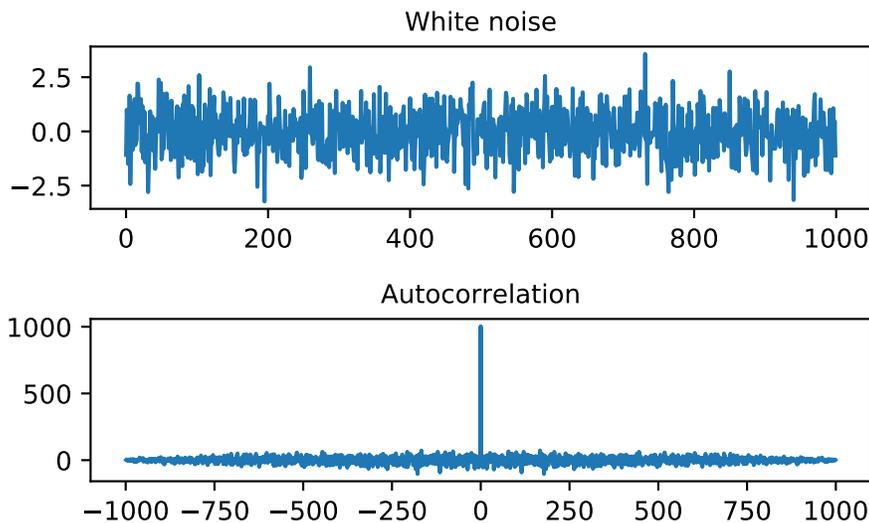

>>> from scipy import misc
>>> face = misc.face(gray=True)
>>> kernel = np.outer(signal.gaussian(70, 8), signal.gaussian(70, 8))
>>> blurred = signal.fftconvolve(face, kernel, mode='same')

```

```

>>> fig, (ax_orig, ax_kernel, ax_blurred) = plt.subplots(3, 1,
...                                                    figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_kernel.imshow(kernel, cmap='gray')
>>> ax_kernel.set_title('Gaussian kernel')
>>> ax_kernel.set_axis_off()
>>> ax_blurred.imshow(blurred, cmap='gray')
>>> ax_blurred.set_title('Blurred')
>>> ax_blurred.set_axis_off()
>>> fig.show()

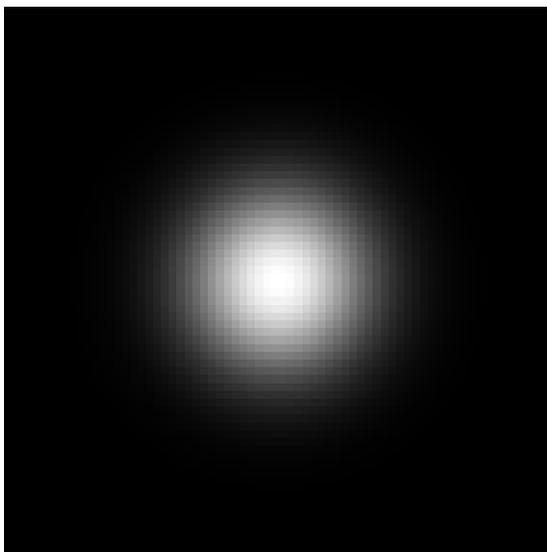

```

Original

Gaussian kernel

Blurred

`scipy.signal.convolve2d`(*in1*, *in2*, *mode*='full', *boundary*='fill', *fillvalue*=0)

Convolve two 2-dimensional arrays.

Convolve *in1* and *in2* with output size determined by *mode*, and boundary conditions determined by *boundary* and *fillvalue*.

**Parameters**

**in1** : array\_like  
First input.

**in2** : array\_like  
Second input. Should have the same number of dimensions as *in1*. If operating in 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.

**mode** : str {'full', 'valid', 'same'}, optional  
A string indicating the size of the output:  
**full**        The output is the full discrete linear convolution of the inputs. (Default)  
**valid**        The output consists only of those elements that do not rely on the zero-padding.  
**same**         The output is the same size as *in1*, centered with respect to the 'full' output.

**boundary** : str {'fill', 'wrap', 'symm'}, optional  
A flag indicating how to handle boundaries:  
**fill**         pad input arrays with *fillvalue*. (default)  
**wrap**         circular boundary conditions.  
**symm**         symmetrical boundary conditions.

**fillvalue** : scalar, optional  
Value to fill pad input arrays with. Default is 0.

**Returns**

**out** : ndarray  
A 2-dimensional array containing a subset of the discrete linear convolution of *in1* with *in2*.

### Examples

Compute the gradient of an image by 2D convolution with a complex Scharr operator. (Horizontal operator is real, vertical is imaginary.) Use symmetric boundary condition to avoid creating edges at the image boundaries.

```
>>> from scipy import signal
>>> from scipy import misc
>>> ascent = misc.ascent()
>>> scharr = np.array([[ -3-3j,  0-10j,  +3 -3j],
...                  [-10+0j,  0+ 0j,  +10 +0j],
...                  [ -3+3j,  0+10j,  +3 +3j]]) # Gx + j*Gy
>>> grad = signal.convolve2d(ascent, scharr, boundary='symm', mode='same')
```

```
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag, ax_ang) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(ascent, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_mag.imshow(np.absolute(grad), cmap='gray')
>>> ax_mag.set_title('Gradient magnitude')
>>> ax_mag.set_axis_off()
>>> ax_ang.imshow(np.angle(grad), cmap='hsv') # hsv is cyclic, like angles
>>> ax_ang.set_title('Gradient orientation')
>>> ax_ang.set_axis_off()
>>> fig.show()
```

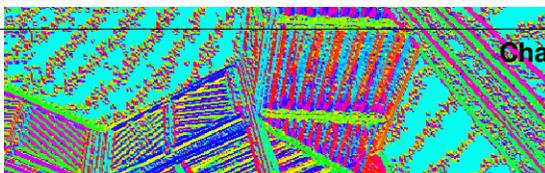

Original

Gradient magnitude

Gradient orientation

`scipy.signal.correlate2d` (*in1*, *in2*, *mode*='full', *boundary*='fill', *fillvalue*=0)

Cross-correlate two 2-dimensional arrays.

Cross correlate *in1* and *in2* with output size determined by *mode*, and boundary conditions determined by *boundary* and *fillvalue*.

**Parameters**

**in1** : array\_like  
First input.

**in2** : array\_like  
Second input. Should have the same number of dimensions as *in1*. If operating in 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.

**mode** : str {'full', 'valid', 'same'}, optional  
A string indicating the size of the output:  
**full**        The output is the full discrete linear cross-correlation of the inputs. (Default)  
**valid**        The output consists only of those elements that do not rely on the zero-padding.  
**same**         The output is the same size as *in1*, centered with respect to the 'full' output.

**boundary** : str {'fill', 'wrap', 'symm'}, optional  
A flag indicating how to handle boundaries:  
**fill**         pad input arrays with *fillvalue*. (default)  
**wrap**         circular boundary conditions.  
**symm**         symmetrical boundary conditions.

**fillvalue** : scalar, optional  
Value to fill pad input arrays with. Default is 0.

**Returns**

**correlate2d** : ndarray  
A 2-dimensional array containing a subset of the discrete linear cross-correlation of *in1* with *in2*.

### Examples

Use 2D cross-correlation to find the location of a template in a noisy image:

```
>>> from scipy import signal
>>> from scipy import misc
>>> face = misc.face(gray=True) - misc.face(gray=True).mean()
>>> template = np.copy(face[300:365, 670:750]) # right eye
>>> template -= template.mean()
>>> face = face + np.random.randn(*face.shape) * 50 # add noise
>>> corr = signal.correlate2d(face, template, boundary='symm', mode='same')
>>> y, x = np.unravel_index(np.argmax(corr), corr.shape) # find the match
```

```
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_template, ax_corr) = plt.subplots(3, 1,
...                                                figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_template.imshow(template, cmap='gray')
>>> ax_template.set_title('Template')
>>> ax_template.set_axis_off()
>>> ax_corr.imshow(corr, cmap='gray')
>>> ax_corr.set_title('Cross-correlation')
>>> ax_corr.set_axis_off()
>>> ax_orig.plot(x, y, 'ro')
>>> fig.show()
```

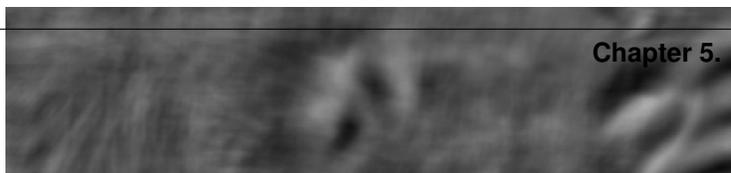

Original

Template

Cross-correlation

`scipy.signal.sepfir2d(input, hrow, hcol) → output`

Description:

Convolve the rank-2 input array with the separable filter defined by the rank-1 arrays `hrow`, and `hcol`. Mirror symmetric boundary conditions are assumed. This function can be used to find an image given its B-spline representation.

`scipy.signal.choose_conv_method(in1, in2, mode='full', measure=False)`

Find the fastest convolution/correlation method.

This primarily exists to be called during the `method='auto'` option in `convolve` and `correlate`, but can also be used when performing many convolutions of the same input shapes and dtypes, determining which method to use for all of them, either to avoid the overhead of the 'auto' option or to use accurate real-world measurements.

**Parameters**

- in1** : array\_like  
The first argument passed into the convolution function.
- in2** : array\_like  
The second argument passed into the convolution function.
- mode** : str { 'full', 'valid', 'same' }, optional  
A string indicating the size of the output:
  - full** : The output is the full discrete linear convolution of the inputs. (Default)
  - valid** : The output consists only of those elements that do not rely on the zero-padding.
  - same** : The output is the same size as `in1`, centered with respect to the 'full' output.
- measure** : bool, optional  
If True, run and time the convolution of `in1` and `in2` with both methods and return the fastest. If False (default), predict the fastest method using precomputed values.

**Returns**

- method** : str  
A string indicating which convolution method is fastest, either 'direct' or 'fft'
- times** : dict, optional  
A dictionary containing the times (in seconds) needed for each method. This value is only returned if `measure=True`.

**See also:**

`convolve`, `correlate`

**Notes**

For large `n`, `measure=False` is accurate and can quickly determine the fastest method to perform the convolution. However, this is not as accurate for small `n` (when any dimension in the input or output is small).

In practice, we found that this function estimates the faster method up to a multiplicative factor of 5 (i.e., the estimated method is *at most* 5 times slower than the fastest method). The estimation values were tuned on an early 2015 MacBook Pro with 8GB RAM but we found that the prediction held *fairly* accurately across different machines.

If `measure=True`, time the convolutions. Because this function uses `fftconvolve`, an error will be thrown if it does not support the inputs. There are cases when `fftconvolve` supports the inputs but this function returns `direct` (e.g., to protect against floating point integer precision).

New in version 0.19.

**Examples**

Estimate the fastest method for a given input:

```
>>> from scipy import signal
>>> a = np.random.randn(1000)
>>> b = np.random.randn(1000000)
>>> method = signal.choose_conv_method(a, b, mode='same')
>>> method
'fft'
```

This can then be applied to other arrays of the same dtype and shape:

```
>>> c = np.random.randn(1000)
>>> d = np.random.randn(1000000)
>>> # `method` works with correlate and convolve
>>> corr1 = signal.correlate(a, b, mode='same', method=method)
>>> corr2 = signal.correlate(c, d, mode='same', method=method)
>>> conv1 = signal.convolve(a, b, mode='same', method=method)
>>> conv2 = signal.convolve(c, d, mode='same', method=method)
```

## 5.20.2 B-splines

<i>bspline</i> (x, n)	B-spline basis function of order n.
<i>cubic</i> (x)	A cubic B-spline.
<i>quadratic</i> (x)	A quadratic B-spline.
<i>gauss_spline</i> (x, n)	Gaussian approximation to B-spline basis function of order n.
<i>cspline1d</i> (signal[, lamb])	Compute cubic spline coefficients for rank-1 array.
<i>qspline1d</i> (signal[, lamb])	Compute quadratic spline coefficients for rank-1 array.
<i>cspline2d</i> ((input {, lambda, precision}) -> ck)	Description:
<i>qspline2d</i> ((input {, lambda, precision}) -> qk)	Description:
<i>cspline1d_eval</i> (cj, newx[, dx, x0])	Evaluate a spline at the new set of points.
<i>qspline1d_eval</i> (cj, newx[, dx, x0])	Evaluate a quadratic spline at the new set of points.
<i>spline_filter</i> (lin[, lmbda])	Smoothing spline (cubic) filtering of a rank-2 array.

`scipy.signal.bspline`(x, n)  
B-spline basis function of order n.

### Notes

Uses `numpy.piecewise` and automatic function-generator.

`scipy.signal.cubic`(x)  
A cubic B-spline.

This is a special case of `bspline`, and equivalent to `bspline(x, 3)`.

`scipy.signal.quadratic`(x)  
A quadratic B-spline.

This is a special case of `bspline`, and equivalent to `bspline(x, 2)`.

`scipy.signal.gauss_spline`(x, n)  
Gaussian approximation to B-spline basis function of order n.

`scipy.signal.cspline1d`(signal, lamb=0.0)  
Compute cubic spline coefficients for rank-1 array.

`scipy.signal.spline_filter` (*lin*, *lmbda*=5.0)  
 Smoothing spline (cubic) filtering of a rank-2 array.

Filter an input data set, *lin*, using a (cubic) smoothing spline of fall-off *lmbda*.

### 5.20.3 Filtering

<code>order_filter(a, domain, rank)</code>	Perform an order filter on an N-dimensional array.
<code>medfilt(volume[, kernel_size])</code>	Perform a median filter on an N-dimensional array.
<code>medfilt2d(input[, kernel_size])</code>	Median filter a 2-dimensional array.
<code>wiener(im[, mysize, noise])</code>	Perform a Wiener filter on an N-dimensional array.
<code>symiirorder1((input, c0, z1 {, ...}))</code>	Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of first-order sections.
<code>symiirorder2((input, r, omega {, ...}))</code>	Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of second-order sections.
<code>lfiltfilt(b, a, x[, axis, zi])</code>	Filter data along one-dimension with an IIR or FIR filter.
<code>lfiltic(b, a, y[, x])</code>	Construct initial conditions for <code>lfilt</code> given input and output vectors.
<code>lfiltfilt_zi(b, a)</code>	Construct initial conditions for <code>lfilt</code> for step response steady-state.
<code>filtfilt(b, a, x[, axis, padtype, padlen, ...])</code>	Apply a digital filter forward and backward to a signal.
<code>savgol_filter(x, window_length, polyorder[, ...])</code>	Apply a Savitzky-Golay filter to an array.
<code>deconvolve(signal, divisor)</code>	Deconvolves <code>divisor</code> out of <code>signal</code> using inverse filtering.
<code>sosfilt(sos, x[, axis, zi])</code>	Filter data along one dimension using cascaded second-order sections.
<code>sosfilt_zi(sos)</code>	Construct initial conditions for <code>sosfilt</code> for step response steady-state.
<code>sosfiltfilt(sos, x[, axis, padtype, padlen])</code>	A forward-backward digital filter using cascaded second-order sections.
<code>hilbert(x[, N, axis])</code>	Compute the analytic signal, using the Hilbert transform.
<code>hilbert2(x[, N])</code>	Compute the '2-D' analytic signal of <i>x</i>
<code>decimate(x, q[, n, ftype, axis, zero_phase])</code>	Downsample the signal after applying an anti-aliasing filter.
<code>detrend(data[, axis, type, bp])</code>	Remove linear trend along <i>axis</i> from data.
<code>resample(x, num[, t, axis, window])</code>	Resample <i>x</i> to <i>num</i> samples using Fourier method along the given <i>axis</i> .
<code>resample_poly(x, up, down[, axis, window])</code>	Resample <i>x</i> along the given <i>axis</i> using polyphase filtering.
<code>upfirdn(h, x[, up, down, axis])</code>	Upsample, FIR filter, and downsample

`scipy.signal.order_filter` (*a*, *domain*, *rank*)  
 Perform an order filter on an N-dimensional array.

Perform an order filter on the array *in*. The *domain* argument acts as a mask centered over each pixel. The non-zero elements of *domain* are used to select elements surrounding each input pixel which are placed in a list. The list is sorted, and the output for that pixel is the element corresponding to *rank* in the sorted list.

**Parameters**    **a** : ndarray

The N-dimensional input array.

**domain** : array\_like

A mask array with the same number of dimensions as *a*. Each dimension should have an odd number of elements.

**rank** : int  
A non-negative integer which selects the element from the sorted list (0 corresponds to the smallest element, 1 is the next smallest element, etc.).

**Returns** **out** : ndarray  
The results of the order filter in an array with the same shape as *a*.

**Examples**

```
>>> from scipy import signal
>>> x = np.arange(25).reshape(5, 5)
>>> domain = np.identity(3)
>>> x
array([[ 0,  1,  2,  3,  4],
       [ 5,  6,  7,  8,  9],
       [10, 11, 12, 13, 14],
       [15, 16, 17, 18, 19],
       [20, 21, 22, 23, 24]])
>>> signal.order_filter(x, domain, 0)
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  2.,  0.],
       [ 0.,  5.,  6.,  7.,  0.],
       [ 0., 10., 11., 12.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]])
>>> signal.order_filter(x, domain, 2)
array([[ 6.,  7.,  8.,  9.,  4.],
       [11., 12., 13., 14.,  9.],
       [16., 17., 18., 19., 14.],
       [21., 22., 23., 24., 19.],
       [20., 21., 22., 23., 24.]])
```

`scipy.signal.medfilt` (*volume*, *kernel\_size=None*)

Perform a median filter on an N-dimensional array.

Apply a median filter to the input array using a local window-size given by *kernel\_size*.

**Parameters** **volume** : array\_like  
An N-dimensional input array.

**kernel\_size** : array\_like, optional  
A scalar or an N-length list giving the size of the median filter window in each dimension. Elements of *kernel\_size* should be odd. If *kernel\_size* is a scalar, then this scalar is used as the size in each dimension. Default size is 3 for each dimension.

**Returns** **out** : ndarray  
An array the same size as input containing the median filtered result.

`scipy.signal.medfilt2d` (*input*, *kernel\_size=3*)

Median filter a 2-dimensional array.

Apply a median filter to the *input* array using a local window-size given by *kernel\_size* (must be odd).

**Parameters** **input** : array\_like  
A 2-dimensional input array.

**kernel\_size** : array\_like, optional  
A scalar or a list of length 2, giving the size of the median filter window in each dimension. Elements of *kernel\_size* should be odd. If *kernel\_size* is a scalar, then this scalar is used as the size in each dimension. Default is a kernel of size (3, 3).

**Returns** **out** : ndarray  
An array the same size as input containing the median filtered result.

`scipy.signal.wiener` (*im*, *mysize*=None, *noise*=None)

Perform a Wiener filter on an N-dimensional array.

Apply a Wiener filter to the N-dimensional array *im*.

**Parameters**

- im** : ndarray  
An N-dimensional array.
- mysize** : int or array\_like, optional  
A scalar or an N-length list giving the size of the Wiener filter window in each dimension. Elements of *mysize* should be odd. If *mysize* is a scalar, then this scalar is used as the size in each dimension.
- noise** : float, optional  
The noise-power to use. If None, then noise is estimated as the average of the local variance of the input.

**Returns**

- out** : ndarray  
Wiener filtered result with the same shape as *im*.

`scipy.signal.symiirorder1` (*input*, *c0*, *z1* {, *precision*}) → output

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of first-order sections. The second section uses a reversed sequence. This implements a system with the following transfer function and mirror-symmetric boundary conditions:

$$H(z) = \frac{c0}{(1-z1/z)(1-z1z)}$$

The resulting signal will have mirror symmetric boundary conditions as well.

**Parameters**

- input** : ndarray  
The input signal.
- c0, z1** : scalar  
Parameters in the transfer function.
- precision** :  
Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

**Returns**

- output** : ndarray  
The filtered signal.

`scipy.signal.symiirorder2` (*input*, *r*, *omega* {, *precision*}) → output

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of second-order sections. The second section uses a reversed sequence. This implements the following transfer function:

$$H(z) = \frac{cs^2}{(1-a2/z-a3/z^2)(1-a2z-a3z^2)}$$

where:

$$\begin{aligned} a2 &= (2 r \cos \omega) \\ a3 &= -r^2 \\ cs &= 1 - 2 r \cos \omega + r^2 \end{aligned}$$

**Parameters**

- input** : ndarray  
The input signal.
- r, omega** : scalar  
Parameters in the transfer function.
- precision** :

**Returns** **output** : ndarray  
 Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.  
 The filtered signal.

`scipy.signal.lfilter` (*b, a, x, axis=-1, zi=None*)

Filter data along one-dimension with an IIR or FIR filter.

Filter a data sequence, *x*, using a digital filter. This works for many fundamental data types (including Object type). The filter is a direct form II transposed implementation of the standard difference equation (see Notes).

**Parameters**

- b** : array\_like  
The numerator coefficient vector in a 1-D sequence.
- a** : array\_like  
The denominator coefficient vector in a 1-D sequence. If *a*[0] is not 1, then both *a* and *b* are normalized by *a*[0].
- x** : array\_like  
An N-dimensional input array.
- axis** : int, optional  
The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
- zi** : array\_like, optional  
Initial conditions for the filter delays. It is a vector (or array of vectors for an N-dimensional input) of length  $\max(\text{len}(a), \text{len}(b)) - 1$ . If *zi* is None or is not given then initial rest is assumed. See *lfiltic* for more information.

**Returns**

- y** : array  
The output of the digital filter.
- zf** : array, optional  
If *zi* is None, this is not returned, otherwise, *zf* holds the final filter delay values.

See also:

**lfiltic** Construct initial conditions for *lfilter*.

**lfilter\_zi** Compute initial state (steady state of step response) for *lfilter*.

**filtfilt** A forward-backward filter, to obtain a filter with linear phase.

**savgol\_filter**

A Savitzky-Golay filter.

**sosfilt** Filter data using cascaded second-order sections.

**sosfiltfilt**

A forward-backward filter using second-order sections.

Notes

The filter function is implemented as a direct II transposed structure. This means that the filter implements:

$$a[0]*y[n] = b[0]*x[n] + b[1]*x[n-1] + \dots + b[M]*x[n-M] \\ - a[1]*y[n-1] - \dots - a[N]*y[n-N]$$

where *M* is the degree of the numerator, *N* is the degree of the denominator, and *n* is the sample number. It is implemented using the following difference equations (assuming *M* = *N*):

$$a[0]*y[n] = b[0] * x[n] + d[0][n-1] \\ d[0][n] = b[1] * x[n] - a[1] * y[n] + d[1][n-1] \\ d[1][n] = b[2] * x[n] - a[2] * y[n] + d[2][n-1] \\ \dots$$

$$\begin{aligned}d[N-2][n] &= b[N-1]*x[n] - a[N-1]*y[n] + d[N-1][n-1] \\d[N-1][n] &= b[N] * x[n] - a[N] * y[n]\end{aligned}$$

where  $d$  are the state variables.

The rational transfer function describing this filter in the  $z$ -transform domain is:

$$Y(z) = \frac{b[0] + b[1]z^{-1} + \dots + b[M]z^{-M}}{a[0] + a[1]z^{-1} + \dots + a[N]z^{-N}} X(z)$$

### Examples

Generate a noisy signal to be filtered:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 201)
>>> x = (np.sin(2*np.pi*0.75*t*(1-t) + 2.1) +
...      0.1*np.sin(2*np.pi*1.25*t + 1) +
...      0.18*np.cos(2*np.pi*3.85*t))
>>> xn = x + np.random.randn(len(t)) * 0.08
```

Create an order 3 lowpass butterworth filter:

```
>>> b, a = signal.butter(3, 0.05)
```

Apply the filter to  $x_n$ . Use `lfilter_zi` to choose the initial condition of the filter:

```
>>> zi = signal.lfilter_zi(b, a)
>>> z, _ = signal.lfilter(b, a, xn, zi=zi*xn[0])
```

Apply the filter again, to have a result filtered at an order the same as `filtfilt`:

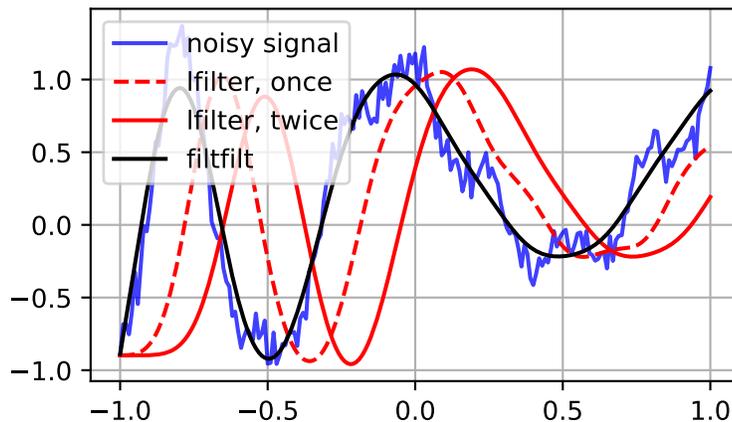

```
>>> z2, _ = signal.lfilter(b, a, z, zi=zi*z[0])
```

Use `filtfilt` to apply the filter:

```
>>> y = signal.filtfilt(b, a, xn)
```

Plot the original signal and the various filtered versions:

```
>>> plt.figure
>>> plt.plot(t, xn, 'b', alpha=0.75)
>>> plt.plot(t, z, 'r--', t, z2, 'r', t, y, 'k')
>>> plt.legend(('noisy signal', 'lfilter, once', 'lfilter, twice',
...          'filtfilt'), loc='best')
>>> plt.grid(True)
>>> plt.show()
```

`scipy.signal.lfiltic` (*b*, *a*, *y*, *x=None*)

Construct initial conditions for `lfilter` given input and output vectors.

Given a linear filter (*b*, *a*) and initial conditions on the output *y* and the input *x*, return the initial conditions on the state vector *zi* which is used by `lfilter` to generate the output given the input.

**Parameters**

- b** : array\_like  
Linear filter term.
- a** : array\_like  
Linear filter term.
- y** : array\_like  
Initial conditions.  
If  $N = \text{len}(a) - 1$ , then  $y = \{y[-1], y[-2], \dots, y[-N]\}$ .  
If *y* is too short, it is padded with zeros.
- x** : array\_like, optional  
Initial conditions.  
If  $M = \text{len}(b) - 1$ , then  $x = \{x[-1], x[-2], \dots, x[-M]\}$ .  
If *x* is not given, its initial conditions are assumed zero.  
If *x* is too short, it is padded with zeros.

**Returns**

- zi** : ndarray  
The state vector  $z_i = \{z_0[-1], z_1[-1], \dots, z_{K-1}[-1]\}$ , where  $K = \max(M, N)$ .

**See also:**

`lfilter`, `lfilter_zi`

`scipy.signal.lfilter_zi` (*b*, *a*)

Construct initial conditions for `lfilter` for step response steady-state.

Compute an initial state *zi* for the `lfilter` function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

**Parameters**

- b, a** : array\_like (1-D)  
The IIR filter coefficients. See `lfilter` for more information.

**Returns**

- zi** : 1-D ndarray  
The initial state for the filter.

**See also:**

*lfilter*, *lfiltic*, *filtfilt*

**Notes**

A linear filter with order  $m$  has a state space representation  $(A, B, C, D)$ , for which the output  $y$  of the filter can be expressed as:

$$\begin{aligned} z(n+1) &= A*z(n) + B*x(n) \\ y(n) &= C*z(n) + D*x(n) \end{aligned}$$

where  $z(n)$  is a vector of length  $m$ ,  $A$  has shape  $(m, m)$ ,  $B$  has shape  $(m, 1)$ ,  $C$  has shape  $(1, m)$  and  $D$  has shape  $(1, 1)$  (assuming  $x(n)$  is a scalar). `lfilter_zi` solves:

$$z_i = A*z_i + B$$

In other words, it finds the initial condition for which the response to an input of all ones is a constant.

Given the filter coefficients  $a$  and  $b$ , the state space matrices for the transposed direct form II implementation of the linear filter, which is the implementation used by `scipy.signal.lfilter`, are:

$$\begin{aligned} A &= \text{scipy.linalg.companion}(a).T \\ B &= b[1:] - a[1:]*b[0] \end{aligned}$$

assuming  $a[0]$  is 1.0; if  $a[0]$  is not 1,  $a$  and  $b$  are first divided by  $a[0]$ .

**Examples**

The following code creates a lowpass Butterworth filter. Then it applies that filter to an array whose values are all 1.0; the output is also all 1.0, as expected for a lowpass filter. If the `zi` argument of `lfilter` had not been given, the output would have shown the transient signal.

```
>>> from numpy import array, ones
>>> from scipy.signal import lfilter, lfilter_zi, butter
>>> b, a = butter(5, 0.25)
>>> zi = lfilter_zi(b, a)
>>> y, zo = lfilter(b, a, ones(10), zi=zi)
>>> y
array([1., 1., 1., 1., 1., 1., 1., 1., 1., 1.])
```

Another example:

```
>>> x = array([0.5, 0.5, 0.5, 0.0, 0.0, 0.0, 0.0])
>>> y, zf = lfilter(b, a, x, zi=zi*x[0])
>>> y
array([ 0.5          ,  0.5          ,  0.5          ,  0.49836039,  0.48610528,
        0.44399389,  0.35505241])
```

Note that the `zi` argument to `lfilter` was computed using `lfilter_zi` and scaled by  $x[0]$ . Then the output  $y$  has no transient until the input drops from 0.5 to 0.0.

`scipy.signal.filtfilt` ( $b, a, x, axis=-1, padtype='odd', padlen=None, method='pad', irlen=None$ )

Apply a digital filter forward and backward to a signal.

This function applies a linear digital filter twice, once forward and once backwards. The combined filter has zero phase and a filter order twice that of the original.

The function provides options for handling the edges of the signal.

**Parameters**  $b$ : (N,) array\_like

The numerator coefficient vector of the filter.

**a** : (N,) array\_like  
The denominator coefficient vector of the filter. If `a[0]` is not 1, then both `a` and `b` are normalized by `a[0]`.

**x** : array\_like  
The array of data to be filtered.

**axis** : int, optional  
The axis of `x` to which the filter is applied. Default is -1.

**padtype** : str or None, optional  
Must be 'odd', 'even', 'constant', or None. This determines the type of extension to use for the padded signal to which the filter is applied. If `padtype` is None, no padding is used. The default is 'odd'.

**padlen** : int or None, optional  
The number of elements by which to extend `x` at both ends of `axis` before applying the filter. This value must be less than `x.shape[axis] - 1`. `padlen=0` implies no padding. The default value is `3 * max(len(a), len(b))`.

**method** : str, optional  
Determines the method for handling the edges of the signal, either "pad" or "gust". When `method` is "pad", the signal is padded; the type of padding is determined by `padtype` and `padlen`, and `irlen` is ignored. When `method` is "gust", Gustafsson's method is used, and `padtype` and `padlen` are ignored.

**irlen** : int or None, optional  
When `method` is "gust", `irlen` specifies the length of the impulse response of the filter. If `irlen` is None, no part of the impulse response is ignored. For a long signal, specifying `irlen` can significantly improve the performance of the filter.

**Returns** **y** : ndarray  
The filtered output with the same shape as `x`.

**See also:**

`sosfiltfilt`, `lfilter_zi`, `lfilter`, `lfiltic`, `savgol_filter`, `sosfilt`

**Notes**

When `method` is "pad", the function pads the data along the given axis in one of three ways: odd, even or constant. The odd and even extensions have the corresponding symmetry about the end point of the data. The constant extension extends the data with the values at the end points. On both the forward and backward passes, the initial condition of the filter is found by using `lfilter_zi` and scaling it by the end point of the extended data.

When `method` is "gust", Gustafsson's method [R252] is used. Initial conditions are chosen for the forward and backward passes so that the forward-backward filter gives the same result as the backward-forward filter.

The option to use Gustafsson's method was added in scipy version 0.16.0.

**References**

[R252]

**Examples**

The examples will use several functions from `scipy.signal`.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

First we create a one second signal that is the sum of two pure sine waves, with frequencies 5 Hz and 250 Hz, sampled at 2000 Hz.

```
>>> t = np.linspace(0, 1.0, 2001)
>>> xlow = np.sin(2 * np.pi * 5 * t)
>>> xhigh = np.sin(2 * np.pi * 250 * t)
>>> x = xlow + xhigh
```

Now create a lowpass Butterworth filter with a cutoff of 0.125 times the Nyquist rate, or 125 Hz, and apply it to *x* with *filtfilt*. The result should be approximately *xlow*, with no phase shift.

```
>>> b, a = signal.butter(8, 0.125)
>>> y = signal.filtfilt(b, a, x, padlen=150)
>>> np.abs(y - xlow).max()
9.1086182074789912e-06
```

We get a fairly clean result for this artificial example because the odd extension is exact, and with the moderately long padding, the filter's transients have dissipated by the time the actual data is reached. In general, transient effects at the edges are unavoidable.

The following example demonstrates the option `method="gust"`.

First, create a filter.

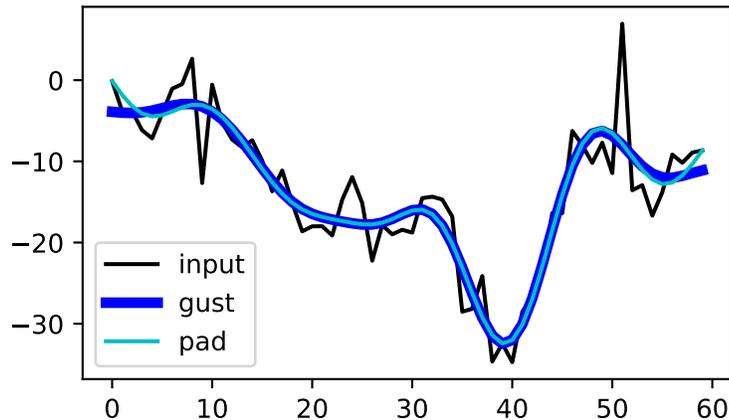

```
>>> b, a = signal.ellip(4, 0.01, 120, 0.125) # Filter to be applied.
>>> np.random.seed(123456)
```

*sig* is a random input signal to be filtered.

```
>>> n = 60
>>> sig = np.random.randn(n)**3 + 3*np.random.randn(n).cumsum()
```

Apply *filtfilt* to *sig*, once using the Gustafsson method, and once using padding, and plot the results for comparison.

```
>>> fgust = signal.filtfilt(b, a, sig, method="gust")
>>> fpad = signal.filtfilt(b, a, sig, padlen=50)
>>> plt.plot(sig, 'k-', label='input')
>>> plt.plot(fgust, 'b-', linewidth=4, label='gust')
>>> plt.plot(fpad, 'c-', linewidth=1.5, label='pad')
>>> plt.legend(loc='best')
>>> plt.show()
```

The *irlen* argument can be used to improve the performance of Gustafsson's method.

Estimate the impulse response length of the filter.

```
>>> z, p, k = signal.tf2zpk(b, a)
>>> eps = 1e-9
>>> r = np.max(np.abs(p))
>>> approx_impulse_len = int(np.ceil(np.log(eps) / np.log(r)))
>>> approx_impulse_len
137
```

Apply the filter to a longer signal, with and without the *irlen* argument. The difference between *y1* and *y2* is small. For long signals, using *irlen* gives a significant performance improvement.

```
>>> x = np.random.randn(5000)
>>> y1 = signal.filtfilt(b, a, x, method='gust')
>>> y2 = signal.filtfilt(b, a, x, method='gust', irlen=approx_impulse_len)
>>> print(np.max(np.abs(y1 - y2)))
1.80056858312e-10
```

`scipy.signal.savgol_filter(x, window_length, polyorder, deriv=0, delta=1.0, axis=-1, mode='interp', cval=0.0)`

Apply a Savitzky-Golay filter to an array.

This is a 1-d filter. If *x* has dimension greater than 1, *axis* determines the axis along which the filter is applied.

**Parameters** *x* : array\_like

The data to be filtered. If *x* is not a single or double precision floating point array, it will be converted to type `numpy.float64` before filtering.

**window\_length** : int

The length of the filter window (i.e. the number of coefficients). *window\_length* must be a positive odd integer. If *mode* is 'interp', *window\_length* must be less than or equal to the size of *x*.

**polyorder** : int

The order of the polynomial used to fit the samples. *polyorder* must be less than *window\_length*.

**deriv** : int, optional

The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

**delta** : float, optional

The spacing of the samples to which the filter will be applied. This is only used if `deriv > 0`. Default is 1.0.

**axis** : int, optional

The axis of the array  $x$  along which the filter is to be applied. Default is -1.

**mode** : str, optional

Must be 'mirror', 'constant', 'nearest', 'wrap' or 'interp'. This determines the type of extension to use for the padded signal to which the filter is applied. When *mode* is 'constant', the padding value is given by *cval*. See the Notes for more details on 'mirror', 'constant', 'wrap', and 'nearest'. When the 'interp' mode is selected (the default), no extension is used. Instead, a degree *polyorder* polynomial is fit to the last *window\_length* values of the edges, and this polynomial is used to evaluate the last *window\_length // 2* output values.

**cval** : scalar, optional

Value to fill past the edges of the input if *mode* is 'constant'. Default is 0.0.

**Returns** **y** : ndarray, same shape as  $x$

The filtered data.

**See also:**

`savgol_coeffs`

**Notes**

Details on the *mode* options:

**'mirror'**: Repeats the values at the edges in reverse order. The value closest to the edge is not included.  
**'nearest'**: The extension contains the nearest input value.  
**'constant'**: The extension contains the value given by the *cval* argument.  
**'wrap'**: The extension contains the values from the other end of the array.

For example, if the input is [1, 2, 3, 4, 5, 6, 7, 8], and *window\_length* is 7, the following shows the extended data for the various *mode* options (assuming *cval* is 0):

mode	Ext	Input	Ext
'mirror'	4 3 2	1 2 3 4 5 6 7 8	7 6 5
'nearest'	1 1 1	1 2 3 4 5 6 7 8	8 8 8
'constant'	0 0 0	1 2 3 4 5 6 7 8	0 0 0
'wrap'	6 7 8	1 2 3 4 5 6 7 8	1 2 3

New in version 0.14.0.

**Examples**

```
>>> from scipy.signal import savgol_filter
>>> np.set_printoptions(precision=2) # For compact display.
>>> x = np.array([2, 2, 5, 2, 1, 0, 1, 4, 9])
```

Filter with a window length of 5 and a degree 2 polynomial. Use the defaults for all other parameters.

```
>>> savgol_filter(x, 5, 2)
array([ 1.66,  3.17,  3.54,  2.86,  0.66,  0.17,  1. ,  4. ,  9. ])
```

Note that the last five values in  $x$  are samples of a parabola, so when *mode*='interp' (the default) is used with *polyorder*=2, the last three values are unchanged. Compare that to, for example, *mode*='nearest':

```
>>> savgol_filter(x, 5, 2, mode='nearest')
array([ 1.74,  3.03,  3.54,  2.86,  0.66,  0.17,  1. ,  4.6 ,  7.97])
```

`scipy.signal.deconvolve` (*signal*, *divisor*)

Deconvolves divisor out of signal using inverse filtering.

Returns the quotient and remainder such that `signal = convolve(divisor, quotient) + remainder`

**Parameters**

- signal** : array\_like  
Signal data, typically a recorded signal
- divisor** : array\_like  
Divisor data, typically an impulse response or filter that was applied to the original signal

**Returns**

- quotient** : ndarray  
Quotient, typically the recovered original signal
- remainder** : ndarray  
Remainder

See also:

[`numpy.polydiv`](#)

performs polynomial division (same operation, but also accepts `poly1d` objects)

**Examples**

Deconvolve a signal that's been filtered:

```
>>> from scipy import signal
>>> original = [0, 1, 0, 0, 1, 1, 0, 0]
>>> impulse_response = [2, 1]
>>> recorded = signal.convolve(impulse_response, original)
>>> recorded
array([0, 2, 1, 0, 2, 3, 1, 0, 0])
>>> recovered, remainder = signal.deconvolve(recorded, impulse_response)
>>> recovered
array([ 0.,  1.,  0.,  0.,  1.,  1.,  0.,  0.]
```

`scipy.signal.sosfilt` (*sos*, *x*, *axis=-1*, *zi=None*)

Filter data along one dimension using cascaded second-order sections.

Filter a data sequence, *x*, using a digital IIR filter defined by *sos*. This is implemented by performing `lfilter` for each second-order section. See `lfilter` for details.

**Parameters**

- sos** : array\_like  
Array of second-order filter coefficients, must have shape `(n_sections, 6)`. Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.
- x** : array\_like  
An N-dimensional input array.
- axis** : int, optional  
The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
- zi** : array\_like, optional  
Initial conditions for the cascaded filter delays. It is a (at least 2D) vector of shape `(n_sections, ..., 2, ...)`, where `..., 2, ...` denotes the shape of *x*, but with `x.shape[axis]` replaced by 2. If *zi* is None or is not given then initial rest (i.e. all zeros) is assumed. Note that

**Returns**

- y** : ndarray
  - these initial conditions are *not* the same as the initial conditions given by *lfiltic* or *lfilter\_zi*.
  - The output of the digital filter.
- zf** : ndarray, optional
  - If *zi* is None, this is not returned, otherwise, *zf* holds the final filter delay values.

**See also:**

*zpk2sos*, *sos2zpk*, *sosfilt\_zi*, *sosfiltfilt*, *sosfreqz*

**Notes**

The filter function is implemented as a series of second-order filters with direct-form II transposed structure. It is designed to minimize numerical precision errors for high-order filters.

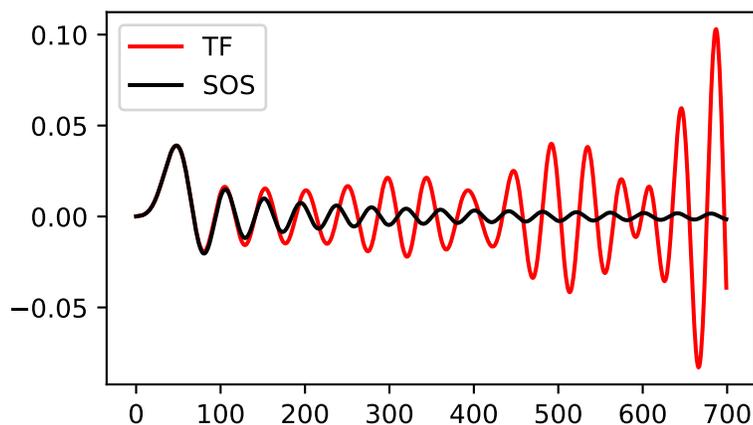

New in version 0.16.0.

**Examples**

Plot a 13th-order filter's impulse response using both *lfilter* and *sosfilt*, showing the instability that results from trying to do a 13th-order filter in a single stage (the numerical error pushes some poles outside of the unit circle):

```

>>> import matplotlib.pyplot as plt
>>> from scipy import signal
>>> b, a = signal.ellip(13, 0.009, 80, 0.05, output='ba')
>>> sos = signal.ellip(13, 0.009, 80, 0.05, output='sos')
>>> x = signal.unit_impulse(700)
>>> y_tf = signal.lfilter(b, a, x)
>>> y_sos = signal.sosfilt(sos, x)
>>> plt.plot(y_tf, 'r', label='TF')
>>> plt.plot(y_sos, 'k', label='SOS')
>>> plt.legend(loc='best')
>>> plt.show()
    
```

`scipy.signal.sosfilt_zi(sos)`

Construct initial conditions for `sosfilt` for step response steady-state.

Compute an initial state  $z_i$  for the `sosfilt` function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

**Parameters** `sos` : array\_like  
 Array of second-order filter coefficients, must have shape  $(n\_sections, 6)$ . See `sosfilt` for the SOS filter format specification.

**Returns** `zi` : ndarray  
 Initial conditions suitable for use with `sosfilt`, shape  $(n\_sections, 2)$ .

**See also:**

`sosfilt`, `zpk2sos`

**Notes**

New in version 0.16.0.

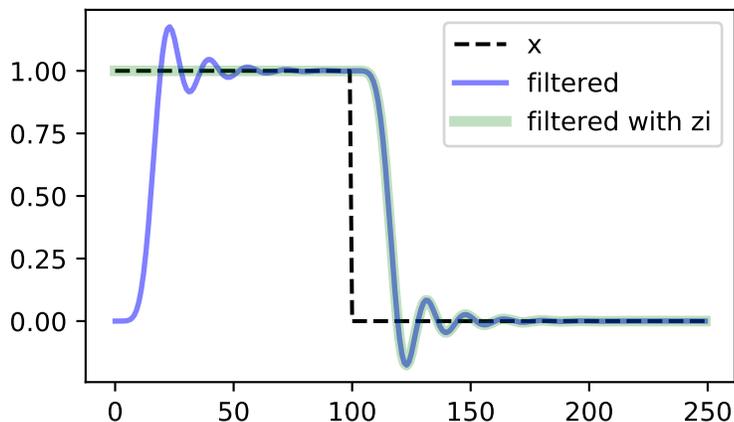

**Examples**

Filter a rectangular pulse that begins at time 0, with and without the use of the `zi` argument of `scipy.signal.sosfilt`.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> sos = signal.butter(9, 0.125, output='sos')
>>> zi = signal.sosfilt_zi(sos)
>>> x = (np.arange(250) < 100).astype(int)
>>> f1 = signal.sosfilt(sos, x)
>>> f2, zo = signal.sosfilt(sos, x, zi=zi)
```

```
>>> plt.plot(x, 'k--', label='x')
>>> plt.plot(f1, 'b', alpha=0.5, linewidth=2, label='filtered')
>>> plt.plot(f2, 'g', alpha=0.25, linewidth=4, label='filtered with zi')
>>> plt.legend(loc='best')
>>> plt.show()
```

`scipy.signal.sosfiltfilt` (*sos*, *x*, *axis=-1*, *padtype='odd'*, *padlen=None*)

A forward-backward digital filter using cascaded second-order sections.

See `filtfilt` for more complete information about this method.

**Parameters**

**sos** : array\_like  
 Array of second-order filter coefficients, must have shape (n\_sections, 6). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

**x** : array\_like  
 The array of data to be filtered.

**axis** : int, optional  
 The axis of *x* to which the filter is applied. Default is -1.

**padtype** : str or None, optional  
 Must be 'odd', 'even', 'constant', or None. This determines the type of extension to use for the padded signal to which the filter is applied. If *padtype* is None, no padding is used. The default is 'odd'.

**padlen** : int or None, optional  
 The number of elements by which to extend *x* at both ends of *axis* before applying the filter. This value must be less than `x.shape[axis] - 1`. `padlen=0` implies no padding. The default value is:

```
3 * (2 * len(sos) + 1 - min((sos[:, 2] == 0).sum(),
                             (sos[:, 5] == 0).sum()))
```

The extra subtraction at the end attempts to compensate for poles and zeros at the origin (e.g. for odd-order filters) to yield equivalent estimates of *padlen* to those of `filtfilt` for second-order section filters built with `scipy.signal` functions.

**Returns**

**y** : ndarray  
 The filtered output with the same shape as *x*.

**See also:**

`filtfilt`, `sosfilt`, `sosfilt_zi`, `sosfreqz`

**Notes**

New in version 0.18.0.

**Examples**

```
>>> from scipy.signal import sosfiltfilt, butter
>>> import matplotlib.pyplot as plt
```

Create an interesting signal to filter.

```
>>> n = 201
>>> t = np.linspace(0, 1, n)
>>> np.random.seed(123)
>>> x = 1 + (t < 0.5) - 0.25*t**2 + 0.05*np.random.randn(n)
```

Create a lowpass Butterworth filter, and use it to filter *x*.

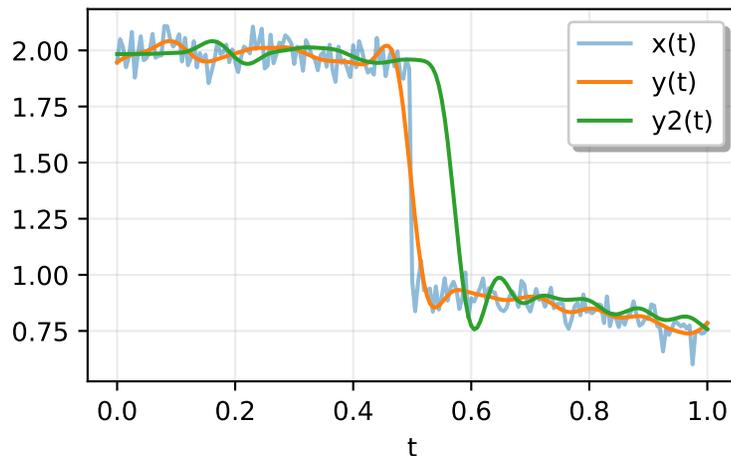

```
>>> sos = butter(4, 0.125, output='sos')
>>> y = sosfiltfilt(sos, x)
```

For comparison, apply an 8th order filter using `sosfilt`. The filter is initialized using the mean of the first four values of `x`.

```
>>> from scipy.signal import sosfilt, sosfilt_zi
>>> sos8 = butter(8, 0.125, output='sos')
>>> zi = x[:4].mean() * sosfilt_zi(sos8)
>>> y2, zo = sosfilt(sos8, x, zi=zi)
```

Plot the results. Note that the phase of `y` matches the input, while `y2` has a significant phase delay.

```
>>> plt.plot(t, x, alpha=0.5, label='x(t)')
>>> plt.plot(t, y, label='y(t)')
>>> plt.plot(t, y2, label='y2(t)')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.xlabel('t')
>>> plt.show()
```

`scipy.signal.hilbert` ( $x$ ,  $N=None$ ,  $axis=-1$ )

Compute the analytic signal, using the Hilbert transform.

The transformation is done along the last axis by default.

**Parameters**

- x** : array\_like  
Signal data. Must be real.
- N** : int, optional  
Number of Fourier components. Default: `x.shape[axis]`
- axis** : int, optional  
Axis along which to do the transformation. Default: -1.

**Returns**

- xa** : ndarray  
Analytic signal of `x`, of each 1-D array along `axis`

See also:

`scipy.fftpack.hilbert`

Return Hilbert transform of a periodic sequence `x`.

### Notes

The analytic signal  $x_a(t)$  of signal  $x(t)$  is:

$$x_a = F^{-1}(F(x)2U) = x + iy$$

where  $F$  is the Fourier transform,  $U$  the unit step function, and  $y$  the Hilbert transform of  $x$ . [R271]

In other words, the negative half of the frequency spectrum is zeroed out, turning the real-valued signal into a complex signal. The Hilbert transformed signal can be obtained from `np.imag(hilbert(x))`, and the original signal from `np.real(hilbert(x))`.

### References

[R271], [R272], [R273]

### Examples

In this example we use the Hilbert transform to determine the amplitude envelope and instantaneous frequency of an amplitude-modulated signal.

```
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import hilbert, chirp
```

```
>>> duration = 1.0
>>> fs = 400.0
>>> samples = int(fs*duration)
>>> t = np.arange(samples) / fs
```

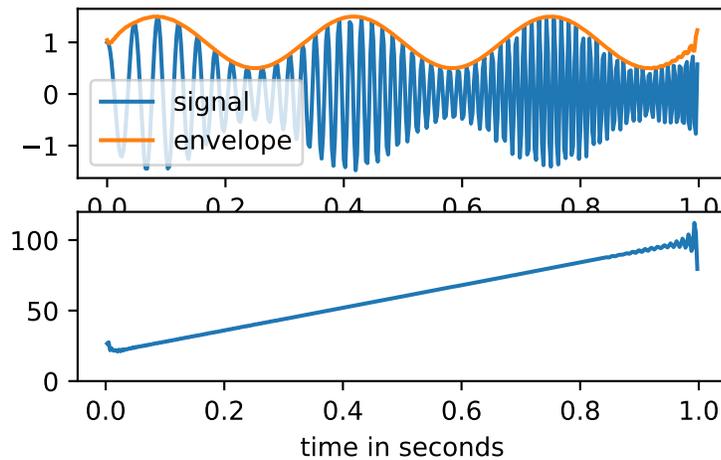

We create a chirp of which the frequency increases from 20 Hz to 100 Hz and apply an amplitude modulation.

```
>>> signal = chirp(t, 20.0, t[-1], 100.0)
>>> signal *= (1.0 + 0.5 * np.sin(2.0*np.pi*3.0*t) )
```

The amplitude envelope is given by magnitude of the analytic signal. The instantaneous frequency can be obtained by differentiating the instantaneous phase in respect to time. The instantaneous phase corresponds to the phase angle of the analytic signal.

```
>>> analytic_signal = hilbert(signal)
>>> amplitude_envelope = np.abs(analytic_signal)
>>> instantaneous_phase = np.unwrap(np.angle(analytic_signal))
>>> instantaneous_frequency = (np.diff(instantaneous_phase) /
...                             (2.0*np.pi) * fs)
```

```
>>> fig = plt.figure()
>>> ax0 = fig.add_subplot(211)
>>> ax0.plot(t, signal, label='signal')
>>> ax0.plot(t, amplitude_envelope, label='envelope')
>>> ax0.set_xlabel("time in seconds")
>>> ax0.legend()
>>> ax1 = fig.add_subplot(212)
>>> ax1.plot(t[1:], instantaneous_frequency)
>>> ax1.set_xlabel("time in seconds")
>>> ax1.set_ylim(0.0, 120.0)
```

`scipy.signal.hilbert2(x, N=None)`

Compute the ‘2-D’ analytic signal of  $x$

**Parameters**

- x** : array\_like  
2-D signal data.
- N** : int or tuple of two ints, optional  
Number of Fourier components. Default is `x.shape`

**Returns**

- xa** : ndarray  
Analytic signal of  $x$  taken along axes (0,1).

### References

[R274]

`scipy.signal.decimate(x, q, n=None, ftype='iir', axis=-1, zero_phase=True)`

Downsample the signal after applying an anti-aliasing filter.

By default, an order 8 Chebyshev type I filter is used. A 30 point FIR filter with Hamming window is used if `ftype` is ‘fir’.

**Parameters**

- x** : array\_like  
The signal to be downsampled, as an N-dimensional array.
- q** : int  
The downsampling factor. When using IIR downsampling, it is recommended to call `decimate` multiple times for downsampling factors higher than 13.
- n** : int, optional  
The order of the filter (1 less than the length for ‘fir’). Defaults to 8 for ‘iir’ and 20 times the downsampling factor for ‘fir’.
- ftype** : str {‘iir’, ‘fir’} or `dlti` instance, optional  
If ‘iir’ or ‘fir’, specifies the type of lowpass filter. If an instance of an `dlti` object, uses that object to filter before downsampling.
- axis** : int, optional  
The axis along which to decimate.
- zero\_phase** : bool, optional  
Prevent phase shift by filtering with `filtfilt` instead of `lfilter` when using an IIR filter, and shifting the outputs back by the filter’s group delay

**Returns** **y** : ndarray  
 when using an FIR filter. The default value of `True` is recommended, since a phase shift is generally not desired.  
 New in version 0.18.0.  
 The down-sampled signal.

**See also:**

**resample** Resample up or down using the FFT method.

**resample\_poly**

Resample using polyphase filtering and an FIR filter.

**Notes**

The `zero_phase` keyword was added in 0.18.0. The possibility to use instances of `dlti` as `ftype` was added in 0.18.0.

`scipy.signal.detrend` (*data*, *axis=-1*, *type='linear'*, *bp=0*)

Remove linear trend along axis from data.

**Parameters** **data** : array\_like

The input data.

**axis** : int, optional

The axis along which to detrend the data. By default this is the last axis (-1).

**type** : {'linear', 'constant'}, optional

The type of detrending. If `type == 'linear'` (default), the result of a linear least-squares fit to *data* is subtracted from *data*. If `type == 'constant'`, only the mean of *data* is subtracted.

**bp** : array\_like of ints, optional

A sequence of break points. If given, an individual linear fit is performed for each part of *data* between two break points. Break points are specified as indices into *data*.

**Returns** **ret** : ndarray

The detrended input data.

**Examples**

```
>>> from scipy import signal
>>> randgen = np.random.RandomState(9)
>>> npoints = 1000
>>> noise = randgen.randn(npoints)
>>> x = 3 + 2*np.linspace(0, 1, npoints) + noise
>>> (signal.detrend(x) - noise).max() < 0.01
True
```

`scipy.signal.resample` (*x*, *num*, *t=None*, *axis=0*, *window=None*)

Resample *x* to *num* samples using Fourier method along the given axis.

The resampled signal starts at the same value as *x* but is sampled with a spacing of `len(x) / num * (spacing of x)`. Because a Fourier method is used, the signal is assumed to be periodic.

**Parameters** **x** : array\_like

The data to be resampled.

**num** : int

The number of samples in the resampled signal.

**t** : array\_like, optional

If *t* is given, it is assumed to be the sample positions associated with the signal data in *x*.

**axis** : int, optional  
The axis of  $x$  that is resampled. Default is 0.

**window** : array\_like, callable, string, float, or tuple, optional  
Specifies the window applied to the signal in the Fourier domain. See below for details.

**Returns** resampled\_x or (resampled\_x, resampled\_t)  
Either the resampled array, or, if  $t$  was given, a tuple containing the resampled array and the corresponding resampled positions.

**See also:**

**decimate** Downsample the signal after applying an FIR or IIR filter.

**resample\_poly**

Resample using polyphase filtering and an FIR filter.

**Notes**

The argument *window* controls a Fourier-domain window that tapers the Fourier spectrum before zero-padding to alleviate ringing in the resampled values for sampled signals you didn't intend to be interpreted as band-limited.

If *window* is a function, then it is called with a vector of inputs indicating the frequency bins (i.e. `fft-freq(x.shape[axis])`).

If *window* is an array of the same length as  $x.shape[axis]$  it is assumed to be the window to be applied directly in the Fourier domain (with dc and low-frequency first).

For any other type of *window*, the function `scipy.signal.get_window` is called to generate the window.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from  $dx$  to  $dx * \text{len}(x) / \text{num}$ .

If  $t$  is not None, then it represents the old sample positions, and the new sample positions will be returned as well as the new samples.

As noted, *resample* uses FFT transformations, which can be very slow if the number of input or output samples is large and prime; see `scipy.fftpack.fft`.

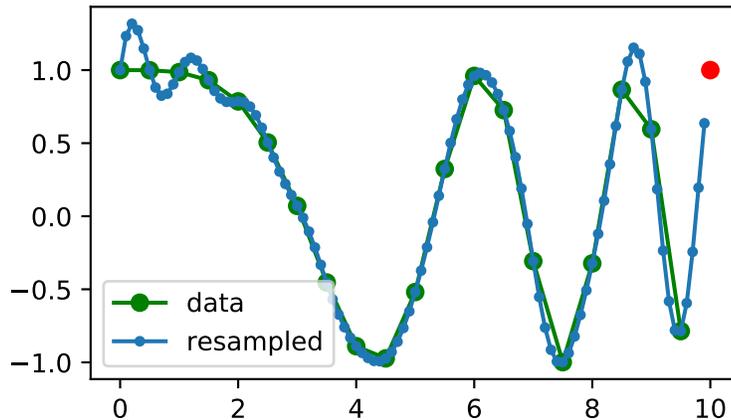

**Examples**

Note that the end of the resampled data rises to meet the first sample of the next cycle:

```
>>> from scipy import signal
```

```
>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f = signal.resample(y, 100)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'go-', xnew, f, '.-', 10, y[0], 'ro')
>>> plt.legend(['data', 'resampled'], loc='best')
>>> plt.show()
```

```
scipy.signal.resample_poly(x, up, down, axis=0, window=('kaiser', 5.0))
```

Resample  $x$  along the given axis using polyphase filtering.

The signal  $x$  is upsampled by the factor  $up$ , a zero-phase low-pass FIR filter is applied, and then it is downsampled by the factor  $down$ . The resulting sample rate is  $up / down$  times the original sample rate. Values beyond the boundary of the signal are assumed to be zero during the filtering step.

**Parameters**

- x** : array\_like  
The data to be resampled.
- up** : int  
The upsampling factor.
- down** : int  
The downsampling factor.
- axis** : int, optional  
The axis of  $x$  that is resampled. Default is 0.
- window** : string, tuple, or array\_like, optional  
Desired window to use to design the low-pass filter, or the FIR filter coefficients to employ. See below for details.

**Returns**

- resampled\_x** : array  
The resampled array.

**See also:**

**decimate** Downsample the signal after applying an FIR or IIR filter.  
**resample** Resample up or down using the FFT method.

**Notes**

This polyphase method will likely be faster than the Fourier method in `scipy.signal.resample` when the number of samples is large and prime, or when the number of samples is large and  $up$  and  $down$  share a large greatest common denominator. The length of the FIR filter used will depend on  $\max(up, down) // \gcd(up, down)$ , and the number of operations during polyphase filtering will depend on the filter length and  $down$  (see `scipy.signal.upfirdn` for details).

The argument `window` specifies the FIR low-pass filter design.

If `window` is an array\_like it is assumed to be the FIR filter coefficients. Note that the FIR filter is applied after the upsampling step, so it should be designed to operate on a signal at a sampling frequency higher than the original by a factor of  $up // \gcd(up, down)$ . This function's output will be centered with respect to this array, so it

is best to pass a symmetric filter with an odd number of samples if, as is usually the case, a zero-phase filter is desired.

For any other type of *window*, the functions `scipy.signal.get_window` and `scipy.signal.firwin` are called to generate the appropriate filter coefficients.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from `dx` to `dx * down / float(up)`.

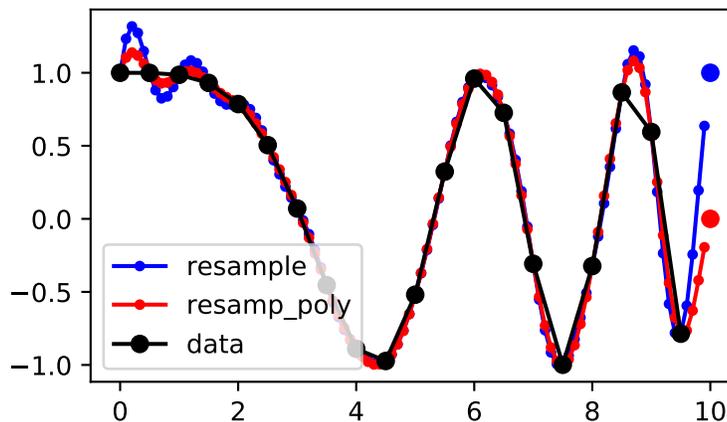

### Examples

Note that the end of the resampled data rises to meet the first sample of the next cycle for the FFT method, and gets closer to zero for the polyphase method:

```
>>> from scipy import signal
```

```
>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f_fft = signal.resample(y, 100)
>>> f_poly = signal.resample_poly(y, 100, 20)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(xnew, f_fft, 'b.-', xnew, f_poly, 'r.-')
>>> plt.plot(x, y, 'ko-')
>>> plt.plot(10, y[0], 'bo', 10, 0., 'ro') # boundaries
>>> plt.legend(['resample', 'resamp_poly', 'data'], loc='best')
>>> plt.show()
```

`scipy.signal.upfirdn` (*h*, *x*, *up*=1, *down*=1, *axis*=-1)

Upsample, FIR filter, and downsample

**Parameters**

- h**: array\_like  
1-dimensional FIR (finite-impulse response) filter coefficients.
- x**: array\_like  
Input signal array.
- up**: int, optional  
Upsampling rate. Default is 1.

	<b>down</b> : int, optional	Downsampling rate. Default is 1.
	<b>axis</b> : int, optional	The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
<b>Returns</b>	<b>y</b> : ndarray	The output signal array. Dimensions will be the same as <i>x</i> except for along <i>axis</i> , which will change size according to the <i>h</i> , <i>up</i> , and <i>down</i> parameters.

### Notes

The algorithm is an implementation of the block diagram shown on page 129 of the Vaidyanathan text [R305] (Figure 4.3-8d).

The direct approach of upsampling by factor of *P* with zero insertion, FIR filtering of length *N*, and downsampling by factor of *Q* is  $O(N*Q)$  per output sample. The polyphase implementation used here is  $O(N/P)$ .

New in version 0.18.

### Examples

Simple operations:

```
>>> from scipy.signal import upfirdn
>>> upfirdn([1, 1, 1], [1, 1, 1]) # FIR filter
array([ 1.,  2.,  3.,  2.,  1.])
>>> upfirdn([1], [1, 2, 3], 3) # upsampling with zeros insertion
array([ 1.,  0.,  0.,  2.,  0.,  0.,  3.,  0.,  0.])
>>> upfirdn([1, 1, 1], [1, 2, 3], 3) # upsampling with sample-and-hold
array([ 1.,  1.,  1.,  2.,  2.,  2.,  3.,  3.,  3.])
>>> upfirdn([.5, 1, .5], [1, 1, 1], 2) # linear interpolation
array([ 0.5,  1.,  1.,  1.,  1.,  1.,  0.5,  0. ])
>>> upfirdn([1], np.arange(10), 1, 3) # decimation by 3
array([ 0.,  3.,  6.,  9.])
>>> upfirdn([.5, 1, .5], np.arange(10), 2, 3) # linear interp, rate 2/3
array([ 0.,  1.,  2.5,  4.,  5.5,  7.,  8.5,  0. ])
```

Apply a single filter to multiple signals:

```
>>> x = np.reshape(np.arange(8), (4, 2))
>>> x
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7]])
```

Apply along the last dimension of *x*:

```
>>> h = [1, 1]
>>> upfirdn(h, x, 2)
array([[ 0.,  0.,  1.,  1.],
       [ 2.,  2.,  3.,  3.],
       [ 4.,  4.,  5.,  5.],
       [ 6.,  6.,  7.,  7.]])
```

Apply along the 0th dimension of *x*:

```
>>> upfirdn(h, x, 2, axis=0)
array([[ 0.,  1.],
       [ 0.,  1.]])
```

```
[ 2., 3.],
 [ 2., 3.],
 [ 4., 5.],
 [ 4., 5.],
 [ 6., 7.],
 [ 6., 7.]])
```

## 5.20.4 Filter design

<i>bilinear</i> (b, a[, fs])	Return a digital filter from an analog one using a bilinear transform.
<i>findfreqs</i> (num, den, N[, kind])	Find array of frequencies for computing the response of an analog filter.
<i>firls</i> (numtaps, bands, desired[, weight, nyq, fs])	FIR filter design using least-squares error minimization.
<i>firwin</i> (numtaps, cutoff[, width, window, ...])	FIR filter design using the window method.
<i>firwin2</i> (numtaps, freq, gain[, nfreqs, ...])	FIR filter design using the window method.
<i>freqs</i> (b, a[, worN, plot])	Compute frequency response of analog filter.
<i>freqs_zpk</i> (z, p, k[, worN])	Compute frequency response of analog filter.
<i>freqz</i> (b[, a, worN, whole, plot])	Compute the frequency response of a digital filter.
<i>freqz_zpk</i> (z, p, k[, worN, whole])	Compute the frequency response of a digital filter in ZPK form.
<i>sosfreqz</i> (sos[, worN, whole])	Compute the frequency response of a digital filter in SOS format.
<i>group_delay</i> (system[, w, whole])	Compute the group delay of a digital filter.
<i>iirdesign</i> (wp, ws, gpass, gstop[, analog, ...])	Complete IIR digital and analog filter design.
<i>iirfilter</i> (N, Wn[, rp, rs, btype, analog, ...])	IIR digital and analog filter design given order and critical points.
<i>kaiser_atten</i> (numtaps, width)	Compute the attenuation of a Kaiser FIR filter.
<i>kaiser_beta</i> (a)	Compute the Kaiser parameter <i>beta</i> , given the attenuation <i>a</i> .
<i>kaiserord</i> (ripple, width)	Determine the filter window parameters for the Kaiser window method.
<i>minimum_phase</i> (h[, method, n_fft])	Convert a linear-phase FIR filter to minimum phase
<i>savgol_coeffs</i> (window_length, polyorder[, ...])	Compute the coefficients for a 1-d Savitzky-Golay FIR filter.
<i>remez</i> (numtaps, bands, desired[, weight, Hz, ...])	Calculate the minimax optimal filter using the Remez exchange algorithm.
<i>unique_roots</i> (p[, tol, rtype])	Determine unique roots and their multiplicities from a list of roots.
<i>residue</i> (b, a[, tol, rtype])	Compute partial-fraction expansion of $b(s) / a(s)$ .
<i>residuez</i> (b, a[, tol, rtype])	Compute partial-fraction expansion of $b(z) / a(z)$ .
<i>invres</i> (r, p, k[, tol, rtype])	Compute $b(s)$ and $a(s)$ from partial fraction expansion.
<i>invresz</i> (r, p, k[, tol, rtype])	Compute $b(z)$ and $a(z)$ from partial fraction expansion.
<i>BadCoefficients</i>	Warning about badly conditioned filter coefficients

`scipy.signal.bilinear` (*b, a, fs=1.0*)

Return a digital filter from an analog one using a bilinear transform.

The bilinear transform substitutes  $(z-1) / (z+1)$  for  $s$ .

`scipy.signal.findfreqs` (*num, den, N, kind='ba'*)

Find array of frequencies for computing the response of an analog filter.

**Parameters**

- num, den** : array\_like, 1-D  
The polynomial coefficients of the numerator and denominator of the transfer function of the filter or LTI system, where the coefficients are ordered from highest to lowest degree. Or, the roots of the transfer function numerator and denominator (i.e. zeroes and poles).
- N** : int  
The length of the array to be computed.
- kind** : str {'ba', 'zp'}, optional  
Specifies whether the numerator and denominator are specified by their polynomial coefficients ('ba'), or their roots ('zp').

**Returns**

- w** : (N,) ndarray  
A 1-D array of frequencies, logarithmically spaced.

**Examples**

Find a set of nine frequencies that span the “interesting part” of the frequency response for the filter with the transfer function

$$H(s) = s / (s^2 + 8s + 25)$$

```
>>> from scipy import signal
>>> signal.findfreqs([1, 0], [1, 8, 25], N=9)
array([[ 1.00000000e-02,  3.16227766e-02,  1.00000000e-01,
         3.16227766e-01,  1.00000000e+00,  3.16227766e+00,
         1.00000000e+01,  3.16227766e+01,  1.00000000e+02]])
```

`scipy.signal.firls` (*numtaps, bands, desired, weight=None, nyq=None, fs=None*)  
FIR filter design using least-squares error minimization.

Calculate the filter coefficients for the linear-phase finite impulse response (FIR) filter which has the best approximation to the desired frequency response described by *bands* and *desired* in the least squares sense (i.e., the integral of the weighted mean-squared error within the specified bands is minimized).

**Parameters**

- numtaps** : int  
The number of taps in the FIR filter. *numtaps* must be odd.
- bands** : array\_like  
A monotonic nondecreasing sequence containing the band edges in Hz. All elements must be non-negative and less than or equal to the Nyquist frequency given by *nyq*.
- desired** : array\_like  
A sequence the same size as *bands* containing the desired gain at the start and end point of each band.
- weight** : array\_like, optional  
A relative weighting to give to each band region when solving the least squares problem. *weight* has to be half the size of *bands*.
- nyq** : float, optional  
*Deprecated. Use 'fs' instead.* Nyquist frequency. Each frequency in *bands* must be between 0 and *nyq* (inclusive). Default is 1.
- fs** : float, optional  
The sampling frequency of the signal. Each frequency in *bands* must be between 0 and *fs*/2 (inclusive). Default is 2.

**Returns**

- coeffs** : ndarray  
Coefficients of the optimal (in a least squares sense) FIR filter.

See also:

*firwin, firwin2, minimum\_phase, remez*

### Notes

This implementation follows the algorithm given in [R254]. As noted there, least squares design has multiple advantages:

1. Optimal in a least-squares sense.
2. Simple, non-iterative method.
3. The general solution can be obtained by solving a linear system of equations.
4. Allows the use of a frequency dependent weighting function.

This function constructs a Type I linear phase FIR filter, which contains an odd number of *coeffs* satisfying for  $n < numtaps$ :

$$coeffs(n) = coeffs(numtaps - 1 - n)$$

The odd number of coefficients and filter symmetry avoid boundary conditions that could otherwise occur at the Nyquist and 0 frequencies (e.g., for Type II, III, or IV variants).

New in version 0.18.

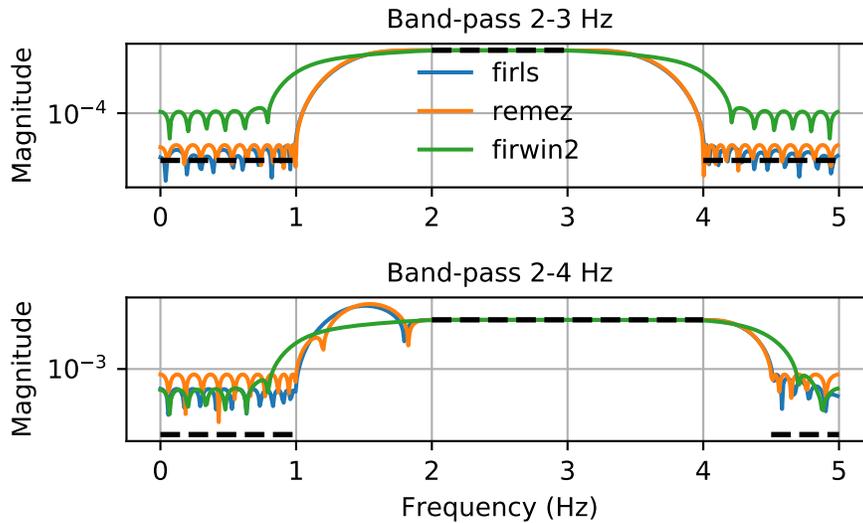

### References

[R254]

### Examples

We want to construct a band-pass filter. Note that the behavior in the frequency ranges between our stop bands and pass bands is unspecified, and thus may overshoot depending on the parameters of our filter:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> fig, axs = plt.subplots(2)
>>> fs = 10.0 # Hz
>>> desired = (0, 0, 1, 1, 0, 0)
>>> for bi, bands in enumerate(((0, 1, 2, 3, 4, 5), (0, 1, 2, 4, 4.5, 5))):
...     fir_firls = signal.firls(73, bands, desired, fs=fs)
...     fir_remez = signal.remez(73, bands, desired[:,2], fs=fs)
...     fir_firwin2 = signal.firwin2(73, bands, desired, fs=fs)
...     hs = list()
...     ax = axs[bi]
...     for fir in (fir_firls, fir_remez, fir_firwin2):
...         freq, response = signal.freqz(fir)
...         hs.append(ax.semilogy(0.5*fs*freq/np.pi, np.abs(response))[0])
...     for band, gains in zip(zip(bands[:,2], bands[1:,2]),
...                             zip(desired[:,2], desired[1:,2])):
...         ax.semilogy(band, np.maximum(gains, 1e-7), 'k--', linewidth=2)
...     if bi == 0:
...         ax.legend(hs, ('firls', 'remez', 'firwin2'),
...                     loc='lower center', frameon=False)
...     else:
...         ax.set_xlabel('Frequency (Hz)')
...     ax.grid(True)
...     ax.set(title='Band-pass %d-%d Hz' % bands[2:4], ylabel='Magnitude')
...
>>> fig.tight_layout()
>>> plt.show()
```

`scipy.signal.firwin` (*numtaps*, *cutoff*, *width=None*, *window='hamming'*, *pass\_zero=True*, *scale=True*, *nyq=None*, *fs=None*)  
 FIR filter design using the window method.

This function computes the coefficients of a finite impulse response filter. The filter will have linear phase; it will be Type I if *numtaps* is odd and Type II if *numtaps* is even.

Type II filters always have zero response at the Nyquist frequency, so a `ValueError` exception is raised if `firwin` is called with *numtaps* even and having a passband whose right end is at the Nyquist frequency.

**Parameters** **numtaps** : int

Length of the filter (number of coefficients, i.e. the filter order + 1). *numtaps* must be even if a passband includes the Nyquist frequency.

**cutoff** : float or 1D array\_like

Cutoff frequency of filter (expressed in the same units as *nyq*) OR an array of cutoff frequencies (that is, band edges). In the latter case, the frequencies in *cutoff* should be positive and monotonically increasing between 0 and *nyq*. The values 0 and *nyq* must not be included in *cutoff*.

**width** : float or None, optional

If *width* is not None, then assume it is the approximate width of the transition region (expressed in the same units as *nyq*) for use in Kaiser FIR filter design. In this case, the *window* argument is ignored.

**window** : string or tuple of string and parameter values, optional

Desired window to use. See `scipy.signal.get_window` for a list of windows and required parameters.

**pass\_zero** : bool, optional

If True, the gain at the frequency 0 (i.e. the “DC gain”) is 1. Otherwise the DC gain is 0.

**scale** : bool, optional

Set to True to scale the coefficients so that the frequency response is exactly unity at a certain frequency. That frequency is either:

- 0 (DC) if the first passband starts at 0 (i.e. *pass\_zero* is True)
- *nyq* (the Nyquist frequency) if the first passband ends at *nyq* (i.e the filter is a single band highpass filter); center of first passband otherwise

**nyq** : float, optional

*Deprecated. Use 'fs' instead.* This is the Nyquist frequency. Each frequency in *cutoff* must be between 0 and *nyq*. Default is 1.

	<b>fs</b> : float, optional	The sampling frequency of the signal. Each frequency in <i>cutoff</i> must be between 0 and $f_s/2$ . Default is 2.
<b>Returns</b>	<b>h</b> : (numtaps,) ndarray	Coefficients of length <i>numtaps</i> FIR filter.
<b>Raises</b>	<b>ValueError</b>	If any value in <i>cutoff</i> is less than or equal to 0 or greater than or equal to $f_s/2$ , if the values in <i>cutoff</i> are not strictly monotonically increasing, or if <i>numtaps</i> is even but a passband includes the Nyquist frequency.

**See also:**

*firwin2*, *firls*, *minimum\_phase*, *remez*

**Examples**

Low-pass from 0 to f:

```
>>> from scipy import signal
>>> numtaps = 3
>>> f = 0.1
>>> signal.firwin(numtaps, f)
array([ 0.06799017,  0.86401967,  0.06799017])
```

Use a specific window function:

```
>>> signal.firwin(numtaps, f, window='nuttall')
array([ 3.56607041e-04,  9.99286786e-01,  3.56607041e-04])
```

High-pass ('stop' from 0 to f):

```
>>> signal.firwin(numtaps, f, pass_zero=False)
array([-0.00859313,  0.98281375, -0.00859313])
```

Band-pass:

```
>>> f1, f2 = 0.1, 0.2
>>> signal.firwin(numtaps, [f1, f2], pass_zero=False)
array([ 0.06301614,  0.88770441,  0.06301614])
```

Band-stop:

```
>>> signal.firwin(numtaps, [f1, f2])
array([-0.00801395,  1.0160279 , -0.00801395])
```

Multi-band (passbands are [0, f1], [f2, f3] and [f4, 1]):

```
>>> f3, f4 = 0.3, 0.4
>>> signal.firwin(numtaps, [f1, f2, f3, f4])
array([-0.01376344,  1.02752689, -0.01376344])
```

Multi-band (passbands are [f1, f2] and [f3,f4]):

```
>>> signal.firwin(numtaps, [f1, f2, f3, f4], pass_zero=False)
array([ 0.04890915,  0.91284326,  0.04890915])
```

`scipy.signal.firwin2` (*numtaps*, *freq*, *gain*, *nfreqs=None*, *window='hamming'*, *nyq=None*, *antisymmetric=False*, *fs=None*)

FIR filter design using the window method.

From the given frequencies *freq* and corresponding gains *gain*, this function constructs an FIR filter with linear phase and (approximately) the given frequency response.

**Parameters**

**numtaps** : int  
The number of taps in the FIR filter. *numtaps* must be less than *nfreqs*.

**freq** : array\_like, 1D  
The frequency sampling points. Typically 0.0 to 1.0 with 1.0 being Nyquist. The Nyquist frequency is half *fs*. The values in *freq* must be nondecreasing. A value can be repeated once to implement a discontinuity. The first value in *freq* must be 0, and the last value must be  $fs/2$ .

**gain** : array\_like  
The filter gains at the frequency sampling points. Certain constraints to gain values, depending on the filter type, are applied, see Notes for details.

**nfreqs** : int, optional  
The size of the interpolation mesh used to construct the filter. For most efficient behavior, this should be a power of 2 plus 1 (e.g, 129, 257, etc). The default is one more than the smallest power of 2 that is not less than *numtaps*. *nfreqs* must be greater than *numtaps*.

**window** : string or (string, float) or float, or None, optional  
Window function to use. Default is “hamming”. See `scipy.signal.get_window` for the complete list of possible values. If None, no window function is applied.

**nyq** : float, optional  
*Deprecated. Use 'fs' instead.* This is the Nyquist frequency. Each frequency in *freq* must be between 0 and *nyq*. Default is 1.

**antisymmetric** : bool, optional  
Whether resulting impulse response is symmetric/antisymmetric. See Notes for more details.

**fs** : float, optional  
The sampling frequency of the signal. Each frequency in *freq* must be between 0 and  $fs/2$ . Default is 2.

**Returns**

**taps** : ndarray  
The filter coefficients of the FIR filter, as a 1-D array of length *numtaps*.

**See also:**

`firls`, `firwin`, `minimum_phase`, `remez`

### Notes

From the given set of frequencies and gains, the desired response is constructed in the frequency domain. The inverse FFT is applied to the desired response to create the associated convolution kernel, and the first *numtaps* coefficients of this kernel, scaled by *window*, are returned.

The FIR filter will have linear phase. The type of filter is determined by the value of ‘numtaps’ and *antisymmetric* flag. There are four possible combinations:

- odd *numtaps*, *antisymmetric* is False, type I filter is produced
- even *numtaps*, *antisymmetric* is False, type II filter is produced
- odd *numtaps*, *antisymmetric* is True, type III filter is produced
- even *numtaps*, *antisymmetric* is True, type IV filter is produced

Magnitude response of all but type I filters are subjects to following constraints:

- type II – zero at the Nyquist frequency
- type III – zero at zero and Nyquist frequencies
- type IV – zero at zero frequency

New in version 0.9.0.

### References

[R255], [R256]

### Examples

A lowpass FIR filter with a response that is 1 on [0.0, 0.5], and that decreases linearly on [0.5, 1.0] from 1 to 0:

```
>>> from scipy import signal
>>> taps = signal.firwin2(150, [0.0, 0.5, 1.0], [1.0, 1.0, 0.0])
>>> print(taps[72:78])
[-0.02286961 -0.06362756  0.57310236  0.57310236 -0.06362756 -0.02286961]
```

`scipy.signal.freqs` (*b*, *a*, *worN=None*, *plot=None*)

Compute frequency response of analog filter.

Given the M-order numerator *b* and N-order denominator *a* of an analog filter, compute its frequency response:

$$H(w) = \frac{b[0]*(jw)**M + b[1]*(jw)**(M-1) + \dots + b[M]}{a[0]*(jw)**N + a[1]*(jw)**(N-1) + \dots + a[N]}$$

**Parameters** **b** : array\_like

Numerator of a linear filter.

**a** : array\_like

Denominator of a linear filter.

**worN** : {None, int, array\_like}, optional

If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g. rad/s) given in *worN*.

**plot** : callable, optional

A callable that takes two arguments. If given, the return parameters *w* and *h* are passed to plot. Useful for plotting the frequency response inside *freqs*.

**Returns** **w** : ndarray

The angular frequencies at which *h* was computed.

**h** : ndarray

The frequency response.

**See also:**

**freqz** Compute the frequency response of a digital filter.

### Notes

Using Matplotlib's "plot" function as the callable for *plot* produces unexpected results, this plots the real part of the complex transfer function, not the magnitude. Try `lambda w, h: plot(w, abs(h))`.

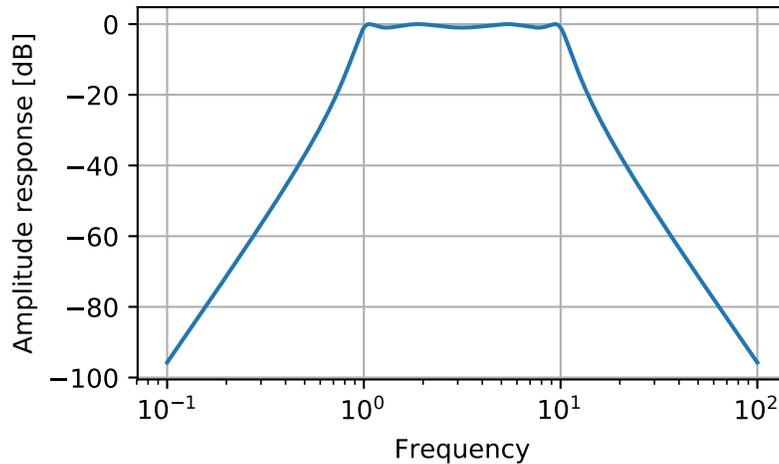

### Examples

```
>>> from scipy.signal import freqs, iirfilter
```

```
>>> b, a = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1')
```

```
>>> w, h = freqs(b, a, worN=np.logspace(-1, 2, 1000))
```

```
>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

`scipy.signal.freqs_zpk` (*z*, *p*, *k*, *worN=None*)

Compute frequency response of analog filter.

Given the zeros *z*, poles *p*, and gain *k* of a filter, compute its frequency response:

$$H(\omega) = k * \frac{(j\omega - z[0]) * (j\omega - z[1]) * \dots * (j\omega - z[-1])}{(j\omega - p[0]) * (j\omega - p[1]) * \dots * (j\omega - p[-1])}$$

**Parameters**

- z** : array\_like  
Zeroes of a linear filter
- p** : array\_like  
Poles of a linear filter
- k** : scalar  
Gain of a linear filter
- worN** : {None, int, array\_like}, optional  
If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g. rad/s) given in *worN*.

**Returns**

- w** : ndarray  
The angular frequencies at which *h* was computed.
- h** : ndarray  
The frequency response.

See also:

- freqs** Compute the frequency response of an analog filter in TF form
- freqz** Compute the frequency response of a digital filter in TF form
- freqz\_zpk** Compute the frequency response of a digital filter in ZPK form

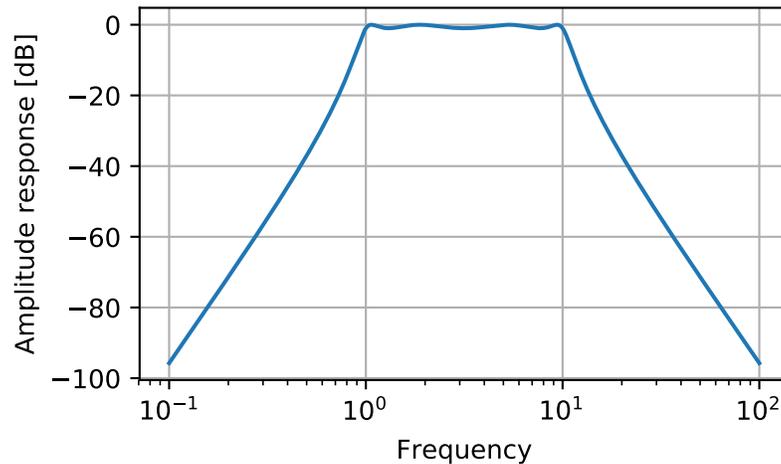

**Notes****Examples**

```
>>> from scipy.signal import freqs_zpk, iirfilter
```

```
>>> z, p, k = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1',
...                    output='zpk')
```

```
>>> w, h = freqs_zpk(z, p, k, worN=np.logspace(-1, 2, 1000))
```

```
>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

`scipy.signal.freqz` (*b*, *a*=1, *worN*=None, *whole*=False, *plot*=None)

Compute the frequency response of a digital filter.

Given the *M*-order numerator *b* and *N*-order denominator *a* of a digital filter, compute its frequency response:

$$H(e^{j\omega}) = \frac{B(e^{j\omega})}{A(e^{j\omega})} = \frac{b[0] + b[1]e^{-j\omega} + \dots + b[M]e^{-j\omega M}}{a[0] + a[1]e^{-j\omega} + \dots + a[N]e^{-j\omega N}}$$

**Parameters** **b**: array\_like

Numerator of a linear filter. If *b* has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and `b.shape[1:]`, `a.shape[1:]`, and the shape of the frequencies array must be compatible for broadcasting.

**a**: array\_like

Denominator of a linear filter. If  $b$  has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and  $b.shape[1:]$ ,  $a.shape[1:]$ , and the shape of the frequencies array must be compatible for broadcasting.

**worN** : {None, int, array\_like}, optional

If None (default), then compute at 512 equally spaced frequencies. If a single integer, then compute at that many frequencies. This is a convenient alternative to:

```
np.linspace(0, 2*pi if whole else pi, N,
            ↪endpoint=False)
```

Using a number that is fast for FFT computations can result in faster computations (see Notes). If an array\_like, compute the response at the frequencies given (in radians/sample).

**whole** : bool, optional

Normally, frequencies are computed from 0 to the Nyquist frequency,  $\pi$  radians/sample (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to  $2\pi$  radians/sample.

**plot** : callable

A callable that takes two arguments. If given, the return parameters  $w$  and  $h$  are passed to plot. Useful for plotting the frequency response inside *freqz*.

#### Returns

**w** : ndarray

The normalized frequencies at which  $h$  was computed, in radians/sample.

**h** : ndarray

The frequency response, as complex numbers.

#### See also:

*freqz\_zpk*, *sosfreqz*

#### Notes

Using Matplotlib's `matplotlib.pyplot.plot` function as the callable for *plot* produces unexpected results, as this plots the real part of the complex transfer function, not the magnitude. Try `lambda w, h: plot(w, np.abs(h))`.

A direct computation via (R)FFT is used to compute the frequency response when the following conditions are met:

1. An integer value is given for *worN*.
2. *worN* is fast to compute via FFT (i.e., `next_fast_len(worN)` equals *worN*).
3. The denominator coefficients are a single value (`a.shape[0] == 1`).
4. *worN* is at least as long as the numerator coefficients (`worN >= b.shape[0]`).
5. If `b.ndim > 1`, then `b.shape[-1] == 1`.

For long FIR filters, the FFT approach can have lower error and be much faster than the equivalent direct polynomial calculation.

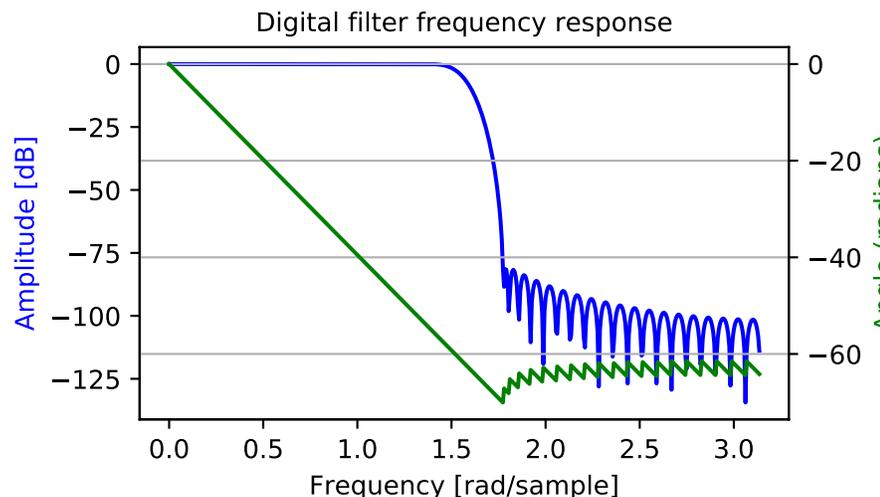

#### Examples

```
>>> from scipy import signal
>>> b = signal.firwin(80, 0.5, window=('kaiser', 8))
>>> w, h = signal.freqz(b)
```

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.title('Digital filter frequency response')
>>> ax1 = fig.add_subplot(111)
```

```
>>> plt.plot(w, 20 * np.log10(abs(h)), 'b')
>>> plt.ylabel('Amplitude [dB]', color='b')
>>> plt.xlabel('Frequency [rad/sample]')
```

```
>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> plt.plot(w, angles, 'g')
>>> plt.ylabel('Angle (radians)', color='g')
>>> plt.grid()
>>> plt.axis('tight')
>>> plt.show()
```

### Broadcasting Examples

Suppose we have two FIR filters whose coefficients are stored in the rows of an array with shape (2, 25). For this demonstration we'll use random data:

```
>>> np.random.seed(42)
>>> b = np.random.rand(2, 25)
```

To compute the frequency response for these two filters with one call to `freqz`, we must pass in `b.T`, because `freqz` expects the first axis to hold the coefficients. We must then extend the shape with a trivial dimension of length 1 to allow broadcasting with the array of frequencies. That is, we pass in `b.T[..., np.newaxis]`, which has shape (25, 2, 1):

```
>>> w, h = signal.freqz(b.T[..., np.newaxis], worN=1024)
>>> w.shape
(1024,)
>>> h.shape
(2, 1024)
```

Now suppose we have two transfer functions, with the same numerator coefficients `b = [0.5, 0.5]`. The coefficients for the two denominators are stored in the first dimension of the two-dimensional array `a`:

```
a = [ 1 1 ]
     [-0.25, -0.5 ]
```

```
>>> b = np.array([0.5, 0.5])
>>> a = np.array([[1, 1], [-0.25, -0.5]])
```

Only *a* is more than one-dimensional. To make it compatible for broadcasting with the frequencies, we extend it with a trivial dimension in the call to *freqz*:

```
>>> w, h = signal.freqz(b, a[..., np.newaxis], worN=1024)
>>> w.shape
(1024,)
>>> h.shape
(2, 1024)
```

`scipy.signal.freqz_zpk(z, p, k, worN=None, whole=False)`

Compute the frequency response of a digital filter in ZPK form.

Given the Zeros, Poles and Gain of a digital filter, compute its frequency response:

$$H(z) = k \prod_i (z - Z[i]) / \prod_j (z - P[j])$$

where *k* is the gain, *Z* are the zeros and *P* are the poles.

<b>Parameters</b>	<b>z</b> : array_like	Zeroes of a linear filter
	<b>p</b> : array_like	Poles of a linear filter
	<b>k</b> : scalar	Gain of a linear filter
	<b>worN</b> : {None, int, array_like}, optional	If single integer (default 512, same as None), then compute at <i>worN</i> frequencies equally spaced around the unit circle. If an array_like, compute the response at the frequencies given (in radians/sample).
	<b>whole</b> : bool, optional	Normally, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If <i>whole</i> is True, compute frequencies from 0 to 2*pi radians/sample.
<b>Returns</b>	<b>w</b> : ndarray	The normalized frequencies at which <i>h</i> was computed, in radians/sample.
	<b>h</b> : ndarray	The frequency response.

See also:

**freqs** Compute the frequency response of an analog filter in TF form  
**freqs\_zpk** Compute the frequency response of an analog filter in ZPK form  
**freqz** Compute the frequency response of a digital filter in TF form

Notes

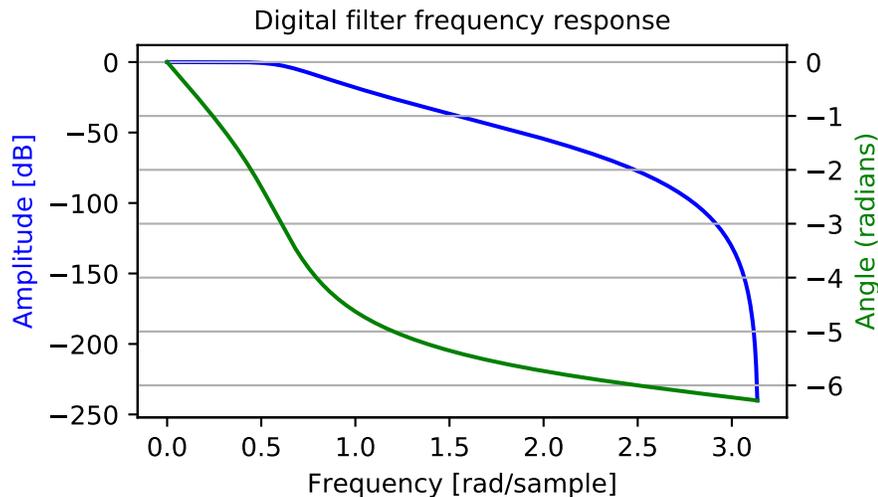

Examples

```
>>> from scipy import signal
>>> z, p, k = signal.butter(4, 0.2, output='zpk')
>>> w, h = signal.freqz_zpk(z, p, k)
```

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.title('Digital filter frequency response')
>>> ax1 = fig.add_subplot(111)
```

```
>>> plt.plot(w, 20 * np.log10(abs(h)), 'b')
>>> plt.ylabel('Amplitude [dB]', color='b')
>>> plt.xlabel('Frequency [rad/sample]')
```

```
>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> plt.plot(w, angles, 'g')
>>> plt.ylabel('Angle (radians)', color='g')
>>> plt.grid()
>>> plt.axis('tight')
>>> plt.show()
```

`scipy.signal.sosfreqz` (*sos*, *worN=None*, *whole=False*)

Compute the frequency response of a digital filter in SOS format.

Given *sos*, an array with shape (n, 6) of second order sections of a digital filter, compute the frequency response of the system function:

$$H(z) = \frac{B_0(z)}{A_0(z)} * \frac{B_1(z)}{A_1(z)} * \dots * \frac{B_{n-1}(z)}{A_{n-1}(z)}$$

for  $z = \exp(\omega j)$ , where  $B\{k\}(z)$  and  $A\{k\}(z)$  are numerator and denominator of the transfer function of the  $k$ -th second order section.

**Parameters** *sos* : array\_like

Array of second-order filter coefficients, must have shape (n\_sections, 6). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

*worN* : {None, int, array\_like}, optional

If None (default), then compute at 512 frequencies equally spaced around the unit circle. If a single integer, then compute at that many frequencies. Using a number that is fast for FFT computations can result in faster computations (see Notes of `freqz`). If an array\_like, compute the response at the frequencies given (in radians/sample; must be 1D).

*whole* : bool, optional

Normally, frequencies are computed from 0 to the Nyquist frequency,  $\pi$  radians/sample (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to  $2\pi$  radians/sample.

**Returns**

**w** : ndarray  
The normalized frequencies at which *h* was computed, in radians/sample.

**h** : ndarray  
The frequency response, as complex numbers.

**See also:***freqz, sosfilt***Notes**

New in version 0.19.0.

**Examples**

Design a 15th-order bandpass filter in SOS format.

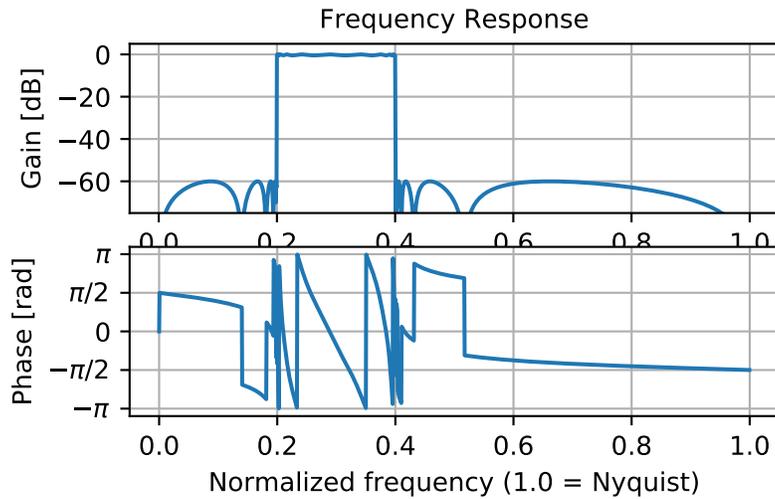

```
>>> from scipy import signal
>>> sos = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
...                       output='sos')
```

Compute the frequency response at 1500 points from DC to Nyquist.

```
>>> w, h = signal.sosfreqz(sos, worN=1500)
```

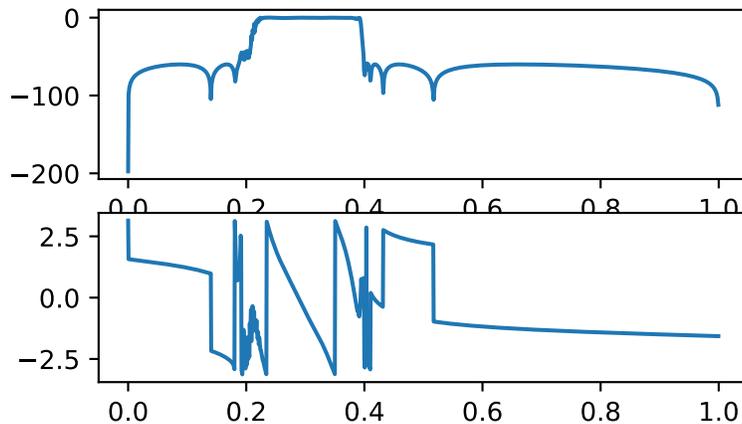

Plot the response.

```
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.abs(h))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.yticks([0, -20, -40, -60])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
...           [r'$-\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.ylabel('Phase [rad]')
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.show()
```

If the same filter is implemented as a single transfer function, numerical error corrupts the frequency response:

```
>>> b, a = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
...                   output='ba')
>>> w, h = signal.freqz(b, a, worN=1500)
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.abs(h))
>>> plt.plot(w/np.pi, db)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.show()
```

`scipy.signal.group_delay(system, w=None, whole=False)`  
 Compute the group delay of a digital filter.

The group delay measures by how many samples amplitude envelopes of various spectral components of a signal are delayed by a filter. It is formally defined as the derivative of continuous (unwrapped) phase:

$$D(\omega) = - \frac{d}{d\omega} \arg H(e^{j\omega})$$

**Parameters**

- system** : tuple of array\_like (b, a)  
Numerator and denominator coefficients of a filter transfer function.
- w** : {None, int, array-like}, optional  
If None (default), then compute at 512 frequencies equally spaced around the unit circle. If a single integer, then compute at that many frequencies. If array, compute the delay at the frequencies given (in radians/sample).
- whole** : bool, optional  
Normally, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to  $2\pi$  radians/sample.

**Returns**

- w** : ndarray  
The normalized frequencies at which the group delay was computed, in radians/sample.
- gd** : ndarray  
The group delay.

**See also:**

**freqz**      Frequency response of a digital filter

#### Notes

The similar function in MATLAB is called *grpdelay*.

If the transfer function  $H(z)$  has zeros or poles on the unit circle, the group delay at corresponding frequencies is undefined. When such a case arises the warning is raised and the group delay is set to 0 at those frequencies.

For the details of numerical computation of the group delay refer to [R258].

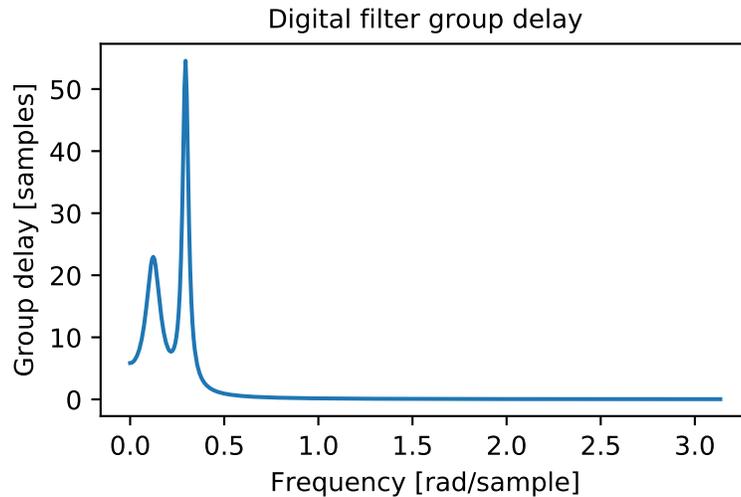

#### References

[R258]

#### Examples

```
>>> from scipy import signal
>>> b, a = signal.iirdesign(0.1, 0.3, 5, 50, ftype='cheby1')
>>> w, gd = signal.group_delay((b, a))
```

```
>>> import matplotlib.pyplot as plt
>>> plt.title('Digital filter group delay')
>>> plt.plot(w, gd)
>>> plt.ylabel('Group delay [samples]')
>>> plt.xlabel('Frequency [rad/sample]')
>>> plt.show()
```

`scipy.signal.iirdesign` (*wp*, *ws*, *gpass*, *gstop*, *analog=False*, *ftype='ellip'*, *output='ba'*)

Complete IIR digital and analog filter design.

Given passband and stopband frequencies and gains, construct an analog or digital IIR filter of minimum order for a given basic type. Return the output in numerator, denominator ('ba'), pole-zero ('zpk') or second order sections ('sos') form.

**Parameters**    **wp, ws** : float

Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: *wp* = 0.2, *ws* = 0.3
- Highpass: *wp* = 0.3, *ws* = 0.2
- Bandpass: *wp* = [0.2, 0.5], *ws* = [0.4, 0.6]
- Bandstop: *wp* = [0.1, 0.6], *ws* = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g. rad/s).

**gpass** : float

The maximum loss in the passband (dB).

**gstop** : float

The minimum attenuation in the stopband (dB).

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

**ftype** : str, optional

The type of IIR filter to design:

- Butterworth: 'butter'
- Chebyshev I: 'cheby1'
- Chebyshev II: 'cheby2'
- Cauchy/elliptic: 'ellip'
- Bessel/Thomson: 'bessel'

**output** : {'ba', 'zpk', 'sos'}, optional

Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

**b, a** : ndarray, ndarray

Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if *output*='ba'.

**z, p, k** : ndarray, ndarray, float

Zeros, poles, and system gain of the IIR filter transfer function. Only returned if *output*='zpk'.

**sos** : ndarray

Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:**

**butter** Filter design using order and critical points

*cheby1, cheby2, ellip, bessel*

**buttord** Find order and critical points from passband and stopband spec

*cheb1ord, cheb2ord, ellipord*

**iirfilter** General filter design using order and critical frequencies

**Notes**

The 'sos' output parameter was added in 0.16.0.

`scipy.signal.iirfilter(N, Wn, rp=None, rs=None, btype='band', analog=False, ftype='butter', output='ba')`

IIR digital and analog filter design given order and critical points.

Design an Nth-order digital or analog filter and return the filter coefficients.

**Parameters** **N** : int

The order of the filter.

**Wn** : array\_like

A scalar or length-2 sequence giving the critical frequencies. For digital filters, *Wn* is normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*Wn* is thus in half-cycles / sample.) For analog filters, *Wn* is an angular frequency (e.g. rad/s).

**rp** : float, optional

For Chebyshev and elliptic filters, provides the maximum ripple in the passband. (dB)

**rs** : float, optional

For Chebyshev and elliptic filters, provides the minimum attenuation in the stop band. (dB)

**btype** : { 'bandpass', 'lowpass', 'highpass', 'bandstop' }, optional

The type of filter. Default is 'bandpass'.

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

**ftype** : str, optional

The type of IIR filter to design:

- Butterworth: 'butter'
- Chebyshev I: 'cheby1'
- Chebyshev II: 'cheby2'
- Cauchy/elliptic: 'ellip'
- Bessel/Thomson: 'bessel'

**output** : { 'ba', 'zpk', 'sos' }, optional

Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

**b, a** : ndarray, ndarray

Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

**z, p, k** : ndarray, ndarray, float

Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

**sos** : ndarray

Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:**

**butter** Filter design using order and critical points

*cheby1, cheby2, ellip, bessel*

**buttord** Find order and critical points from passband and stopband spec

*cheb1ord, cheb2ord, ellipord*

**iirdesign** General filter design using passband and stopband spec

### Notes

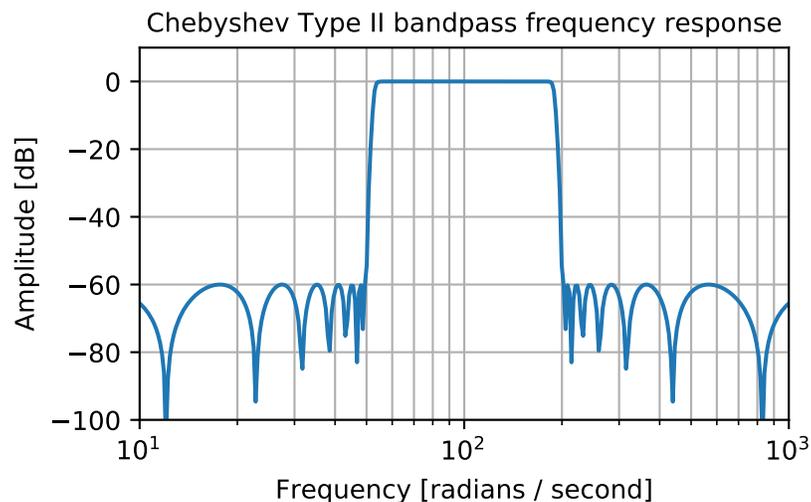

The 'sos' output parameter was added in 0.16.0.

### Examples

Generate a 17th-order Chebyshev II bandpass filter and plot the frequency response:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.iirfilter(17, [50, 200], rs=60, btype='band',
...                          analog=True, ftype='cheby2')
>>> w, h = signal.freqs(b, a, 1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.semilogx(w, 20 * np.log10(abs(h)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [radians / second]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
>>> ax.grid(which='both', axis='both')
>>> plt.show()
```

`scipy.signal.kaiser_atten(numtaps, width)`

Compute the attenuation of a Kaiser FIR filter.

Given the number of taps  $N$  and the transition width  $width$ , compute the attenuation  $a$  in dB, given by Kaiser's formula:

$$a = 2.285 * (N - 1) * \pi * width + 7.95$$

**Parameters**

- numtaps** : int  
The number of taps in the FIR filter.
- width** : float  
The desired width of the transition region between passband and stopband (or, in general, at any discontinuity) for the filter, expressed as a fraction of the Nyquist frequency.

**Returns**

- a** : float  
The attenuation of the ripple, in dB.

**See also:**

*kaiserord*, *kaiser\_beta*

**Examples**

Suppose we want to design a FIR filter using the Kaiser window method that will have 211 taps and a transition width of 9 Hz for a signal that is sampled at 480 Hz. Expressed as a fraction of the Nyquist frequency, the width is  $9/(0.5*480) = 0.0375$ . The approximate attenuation (in dB) is computed as follows:

```

>>> from scipy.signal import kaiser_atten
>>> kaiser_atten(211, 0.0375)
64.48099630593983
    
```

`scipy.signal.kaiser_beta(a)`

Compute the Kaiser parameter *beta*, given the attenuation *a*.

**Parameters**

- a** : float  
The desired attenuation in the stopband and maximum ripple in the passband, in dB. This should be a *positive* number.

**Returns**

- beta** : float  
The *beta* parameter to be used in the formula for a Kaiser window.

**References**

Oppenheim, Schafer, “Discrete-Time Signal Processing”, p.475-476.

**Examples**

Suppose we want to design a lowpass filter, with 65 dB attenuation in the stop band. The Kaiser window parameter to be used in the window method is computed by *kaiser\_beta(65)*:

```

>>> from scipy.signal import kaiser_beta
>>> kaiser_beta(65)
6.20426
    
```

`scipy.signal.kaiserord(ripple, width)`

Determine the filter window parameters for the Kaiser window method.

The parameters returned by this function are generally used to create a finite impulse response filter using the window method, with either *firwin* or *firwin2*.

**Parameters**

- ripple** : float  
Upper bound for the deviation (in dB) of the magnitude of the filter’s frequency response from that of the desired filter (not including frequencies in any transition intervals). That is, if *w* is the frequency expressed as a fraction of the Nyquist frequency, *A(w)* is the actual frequency response of the filter and *D(w)* is the desired frequency response, the design requirement is that:

```
abs(A(w) - D(w)) < 10**(-ripple/20)
```

for  $0 \leq w \leq 1$  and  $w$  not in a transition interval.

**width** : float

Width of transition region, normalized so that 1 corresponds to pi radians / sample. That is, the frequency is expressed as a fraction of the Nyquist frequency.

**Returns**

**numtaps** : int

The length of the Kaiser window.

**beta** : float

The beta parameter for the Kaiser window.

**See also:**

*kaiser\_beta*, *kaiser\_atten*

**Notes**

There are several ways to obtain the Kaiser window:

- `signal.kaiser(numtaps, beta, sym=True)`
- `signal.get_window(beta, numtaps)`
- `signal.get_window('kaiser', beta), numtaps)`

The empirical equations discovered by Kaiser are used.

**References**

Oppenheim, Schafer, “Discrete-Time Signal Processing”, p.475-476.

**Examples**

We will use the Kaiser window method to design a lowpass FIR filter for a signal that is sampled at 1000 Hz.

We want at least 65 dB rejection in the stop band, and in the pass band the gain should vary no more than 0.5%.

We want a cutoff frequency of 175 Hz, with a transition between the pass band and the stop band of 24 Hz. That is, in the band [0, 163], the gain varies no more than 0.5%, and in the band [187, 500], the signal is attenuated by at least 65 dB.

```
>>> from scipy.signal import kaiserord, firwin, freqz
>>> import matplotlib.pyplot as plt
>>> fs = 1000.0
>>> cutoff = 175
>>> width = 24
```

The Kaiser method accepts just a single parameter to control the pass band ripple and the stop band rejection, so we use the more restrictive of the two. In this case, the pass band ripple is 0.005, or 46.02 dB, so we will use 65 dB as the design parameter.

Use *kaiserord* to determine the length of the filter and the parameter for the Kaiser window.

```
>>> numtaps, beta = kaiserord(65, width/(0.5*fs))
>>> numtaps
167
>>> beta
6.20426
```

Use *firwin* to create the FIR filter.

```
>>> taps = firwin(numtaps, cutoff, window='kaiser', beta),
...               scale=False, nyq=0.5*fs)
```

Compute the frequency response of the filter.  $w$  is the array of frequencies, and  $h$  is the corresponding complex array of frequency responses.

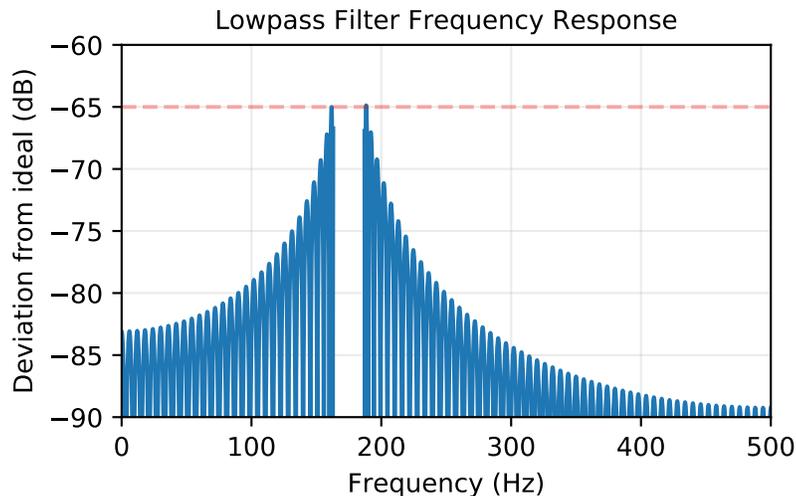

```
>>> w, h = freqz(taps, worN=8000)
>>> w *= 0.5*fs/np.pi # Convert w to Hz.
```

Compute the deviation of the magnitude of the filter's response from that of the ideal lowpass filter. Values in the transition region are set to `nan`, so they won't appear in the plot.

```
>>> ideal = w < cutoff # The "ideal" frequency response.
>>> deviation = np.abs(np.abs(h) - ideal)
>>> deviation[(w > cutoff - 0.5*width) & (w < cutoff + 0.5*width)] = np.nan
```

Plot the deviation. A close look at the left end of the stop band shows that the requirement for 65 dB attenuation is violated in the first lobe by about 0.125 dB. This is not unusual for the Kaiser window method.

```
>>> plt.plot(w, 20*np.log10(np.abs(deviation)))
>>> plt.xlim(0, 0.5*fs)
>>> plt.ylim(-90, -60)
>>> plt.grid(alpha=0.25)
>>> plt.axhline(-65, color='r', ls='--', alpha=0.3)
>>> plt.xlabel('Frequency (Hz)')
>>> plt.ylabel('Deviation from ideal (dB)')
>>> plt.title('Lowpass Filter Frequency Response')
>>> plt.show()
```

`scipy.signal.minimum_phase` ( $h$ , *method*='homomorphic', *n\_fft*=None)

Convert a linear-phase FIR filter to minimum phase

**Parameters** **h** : array

Linear-phase FIR filter coefficients.

**method** : {'hilbert', 'homomorphic'}

The method to use:

**'homomorphic' (default)**

This method [R289] [R290] works best with filters with an odd number of taps, and the resulting minimum phase filter will have a magnitude response that approximates the

square root of the the original filter's magnitude response.

**'hilbert'** This method [R286] is designed to be used with equiripple filters (e.g., from *remez*) with unity or zero gain regions.

**n\_fft** : int  
The number of points to use for the FFT. Should be at least a few times larger than the signal length (see Notes).

**Returns** **h\_minimum** : array  
The minimum-phase version of the filter, with length  $(\text{length}(h) + 1) // 2$ .

**See also:**

*firwin*, *firwin2*, *remez*

**Notes**

Both the Hilbert [R286] or homomorphic [R289] [R290] methods require selection of an FFT length to estimate the complex cepstrum of the filter.

In the case of the Hilbert method, the deviation from the ideal spectrum *epsilon* is related to the number of stopband zeros *n\_stop* and FFT length *n\_fft* as:

```
epsilon = 2. * n_stop / n_fft
```

For example, with 100 stopband zeros and a FFT length of 2048, *epsilon* = 0.0976. If we conservatively assume that the number of stopband zeros is one less than the filter length, we can take the FFT length to be the next power of 2 that satisfies *epsilon*=0.01 as:

```
n_fft = 2 ** int(np.ceil(np.log2(2 * (len(h) - 1) / 0.01)))
```

This gives reasonable results for both the Hilbert and homomorphic methods, and gives the value used when *n\_fft*=None.

Alternative implementations exist for creating minimum-phase filters, including zero inversion [R287] and spectral factorization [R288] [R289]. For more information, see:

<http://dspguru.com/dsp/howtos/how-to-design-minimum-phase-fir-filters>

**References**

[R286], [R287], [R288], [R289], [R290]

**Examples**

Create an optimal linear-phase filter, then convert it to minimum phase:

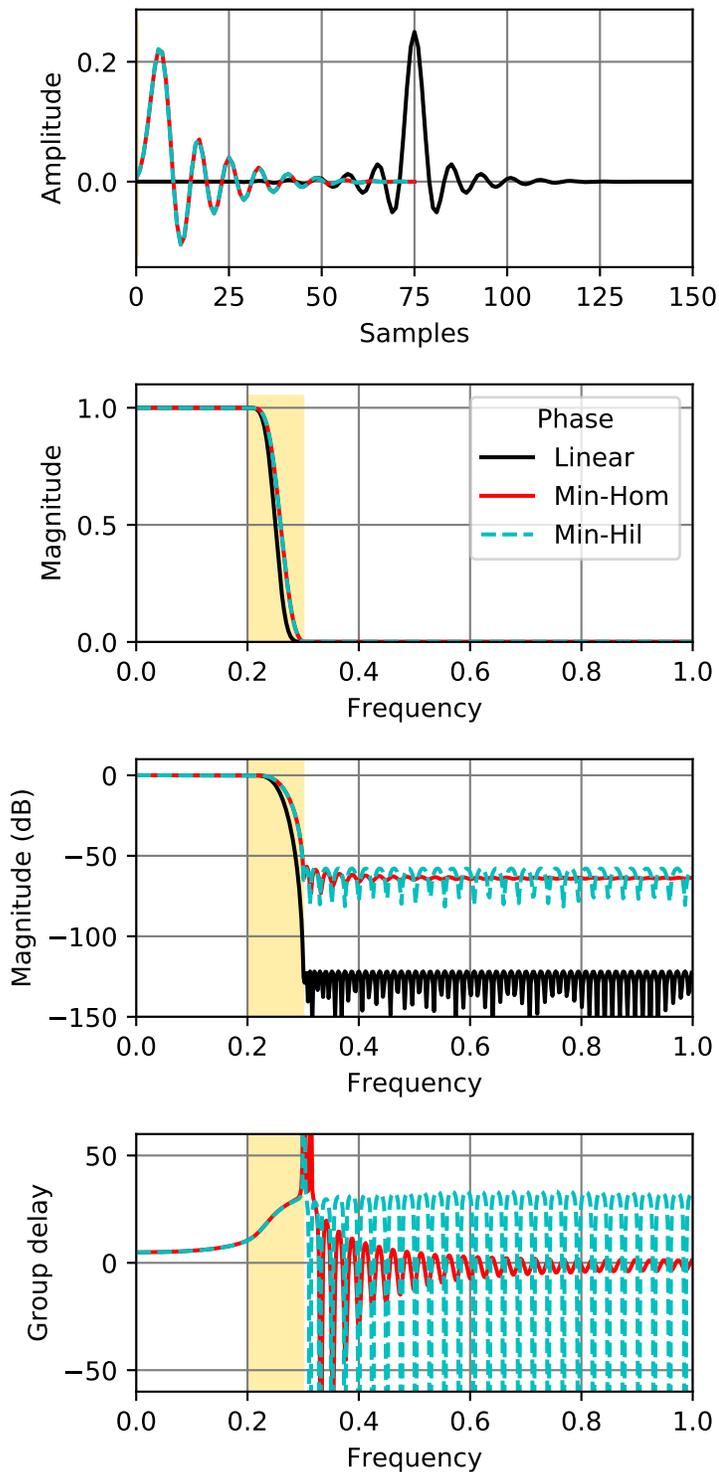

```
>>> from scipy.signal import remez, minimum_phase, freqz, group_delay
>>> import matplotlib.pyplot as plt
>>> freq = [0, 0.2, 0.3, 1.0]
>>> desired = [1, 0]
>>> h_linear = remez(151, freq, desired, Hz=2.)
```

Convert it to minimum phase:

```
>>> h_min_hom = minimum_phase(h_linear, method='homomorphic')
>>> h_min_hil = minimum_phase(h_linear, method='hilbert')
```

Compare the three filters:

```
>>> fig, axs = plt.subplots(4, figsize=(4, 8))
>>> for h, style, color in zip((h_linear, h_min_hom, h_min_hil),
...                           ('-', '-', '--'), ('k', 'r', 'c')):
...     w, H = freqz(h)
...     w, gd = group_delay((h, 1))
...     w /= np.pi
...     axs[0].plot(h, color=color, linestyle=style)
...     axs[1].plot(w, np.abs(H), color=color, linestyle=style)
...     axs[2].plot(w, 20 * np.log10(np.abs(H)), color=color, linestyle=style)
...     axs[3].plot(w, gd, color=color, linestyle=style)
>>> for ax in axs:
...     ax.grid(True, color='0.5')
...     ax.fill_between(freq[1:3], *ax.get_ylim(), color='#ffeeaa', zorder=1)
>>> axs[0].set(xlim=[0, len(h_linear) - 1], ylabel='Amplitude', xlabel='Samples')
>>> axs[1].legend(['Linear', 'Min-Hom', 'Min-Hil'], title='Phase')
>>> for ax, ylim in zip(axs[1:], ([0, 1.1], [-150, 10], [-60, 60])):
...     ax.set(xlim=[0, 1], ylim=ylim, xlabel='Frequency')
>>> axs[1].set(ylabel='Magnitude')
>>> axs[2].set(ylabel='Magnitude (dB)')
>>> axs[3].set(ylabel='Group delay')
>>> plt.tight_layout()
```

```
scipy.signal.savgol_coeffs(window_length, polyorder, deriv=0, delta=1.0, pos=None,
                           use='conv')
```

Compute the coefficients for a 1-d Savitzky-Golay FIR filter.

**Parameters** **window\_length** : int

The length of the filter window (i.e. the number of coefficients). *win-*

*dow\_length* must be an odd positive integer.

**polyorder** : int

The order of the polynomial used to fit the samples. *polyorder* must be less than *window\_length*.

**deriv** : int, optional

The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

**delta** : float, optional

The spacing of the samples to which the filter will be applied. This is only used if *deriv* > 0.

**pos** : int or None, optional

If *pos* is not None, it specifies evaluation position within the window. The default is the middle of the window.

**use** : str, optional

Either 'conv' or 'dot'. This argument chooses the order of the coefficients. The default is 'conv', which means that the coefficients are ordered to be used in a convolution. With *use*='dot', the order is reversed, so the filter is applied by dotting the coefficients with the data set.

**Returns**

**coeffs** : 1-d ndarray

The filter coefficients.

**See also:**

*savgol\_filter*

**Notes**

New in version 0.14.0.

**References**

A. Savitzky, M. J. E. Golay, Smoothing and Differentiation of Data by Simplified Least Squares Procedures. Analytical Chemistry, 1964, 36 (8), pp 1627-1639.

**Examples**

```
>>> from scipy.signal import savgol_coeffs
>>> savgol_coeffs(5, 2)
array([-0.08571429,  0.34285714,  0.48571429,  0.34285714, -0.08571429])
>>> savgol_coeffs(5, 2, deriv=1)
array([ 2.00000000e-01,  1.00000000e-01,  2.00607895e-16,
        -1.00000000e-01, -2.00000000e-01])
```

Note that *use*='dot' simply reverses the coefficients.

```
>>> savgol_coeffs(5, 2, pos=3)
array([ 0.25714286,  0.37142857,  0.34285714,  0.17142857, -0.14285714])
>>> savgol_coeffs(5, 2, pos=3, use='dot')
array([-0.14285714,  0.17142857,  0.34285714,  0.37142857,  0.25714286])
```

*x* contains data from the parabola  $x = t^2$ , sampled at  $t = -1, 0, 1, 2, 3$ . *c* holds the coefficients that will compute the derivative at the last position. When dotted with *x* the result should be 6.

```
>>> x = np.array([1, 0, 1, 4, 9])
>>> c = savgol_coeffs(5, 2, pos=4, deriv=1, use='dot')
>>> c.dot(x)
6.0000000000000018
```

`scipy.signal.remez` (*numtaps*, *bands*, *desired*, *weight=None*, *Hz=None*, *type='bandpass'*, *maxiter=25*, *grid\_density=16*, *fs=None*)

Calculate the minimax optimal filter using the Remez exchange algorithm.

Calculate the filter-coefficients for the finite impulse response (FIR) filter whose transfer function minimizes the maximum error between the desired gain and the realized gain in the specified frequency bands using the Remez exchange algorithm.

**Parameters**    **numtaps** : int

The desired number of taps in the filter. The number of taps is the number of terms in the filter, or the filter order plus one.

**bands** : array\_like

A monotonic sequence containing the band edges. All elements must be non-negative and less than half the sampling frequency as given by *fs*.

**desired** : array\_like

A sequence half the size of *bands* containing the desired gain in each of the specified bands.

**weight** : array\_like, optional

A relative weighting to give to each band region. The length of *weight* has to be half the length of *bands*.

**Hz** : scalar, optional

*Deprecated. Use 'fs' instead.* The sampling frequency in Hz. Default is 1.

**type** : {'bandpass', 'differentiator', 'hilbert'}, optional

The type of filter:

- **'bandpass'** : flat response in bands. This is the default.
- **'differentiator'** : frequency proportional response in bands.
- **'hilbert'** : [filter with odd symmetry, that is, type III] (for even order) or type IV (for odd order) linear phase filters.

**maxiter** : int, optional

Maximum number of iterations of the algorithm. Default is 25.

**grid\_density** : int, optional

Grid density. The dense grid used in *remez* is of size  $(\text{numtaps} + 1) * \text{grid\_density}$ . Default is 16.

**fs** : float, optional

The sampling frequency of the signal. Default is 1.

**Returns**

**out** : ndarray

A rank-1 array containing the coefficients of the optimal (in a minimax sense) filter.

**See also:**

*firls*, *firwin*, *firwin2*, *minimum\_phase*

**References**

[R296], [R297]

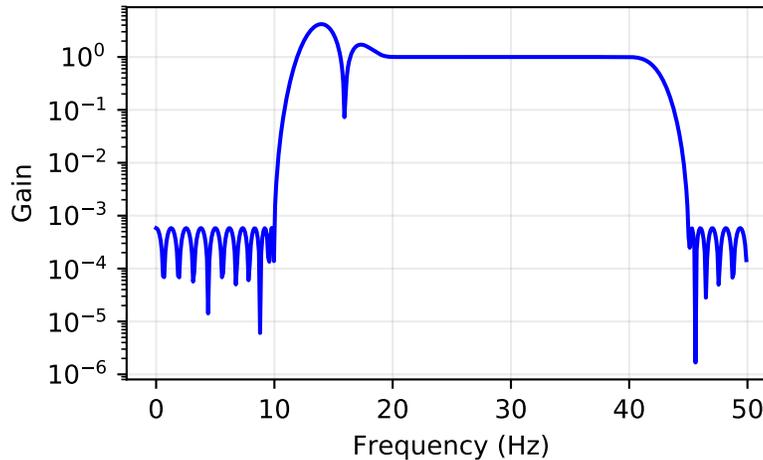

**Examples**

For a signal sampled at 100 Hz, we want to construct a filter with a passband at 20-40 Hz, and stop bands at 0-10 Hz and 45-50 Hz. Note that this means that the behavior in the frequency ranges between those bands is unspecified and may overshoot.

```
>>> from scipy import signal
>>> fs = 100
>>> bpass = signal.remez(72, [0, 10, 20, 40, 45, 50], [0, 1, 0], fs=fs)
>>> freq, response = signal.freqz(bpass)
```

```

>>> import matplotlib.pyplot as plt
>>> plt.semilogy(0.5*fs*freq/np.pi, np.abs(response), 'b-')
>>> plt.grid(alpha=0.25)
>>> plt.xlabel('Frequency (Hz)')
>>> plt.ylabel('Gain')
>>> plt.show()
    
```

`scipy.signal.unique_roots` ( $p$ ,  $tol=0.001$ ,  $rtype='min'$ )

Determine unique roots and their multiplicities from a list of roots.

**Parameters** **p** : array\_like

The list of roots.

**tol** : float, optional

The tolerance for two roots to be considered equal. Default is 1e-3.

**rtype** : {'max', 'min', 'avg'}, optional

How to determine the returned root if multiple roots are within  $tol$  of each other.

- 'max': pick the maximum of those roots.
- 'min': pick the minimum of those roots.
- 'avg': take the average of those roots.

**Returns** **pout** : ndarray

The list of unique roots, sorted from low to high.

**mult** : ndarray

The multiplicity of each root.

### Notes

This utility function is not specific to roots but can be used for any sequence of values for which uniqueness and multiplicity has to be determined. For a more general routine, see `numpy.unique`.

### Examples

```

>>> from scipy import signal
>>> vals = [0, 1.3, 1.31, 2.8, 1.25, 2.2, 10.3]
>>> uniq, mult = signal.unique_roots(vals, tol=2e-2, rtype='avg')
    
```

Check which roots have multiplicity larger than 1:

```
>>> uniq[mult > 1]
array([ 1.305])
```

`scipy.signal.residue` (*b*, *a*, *tol*=0.001, *rtype*='avg')

Compute partial-fraction expansion of  $b(s) / a(s)$ .

If  $M$  is the degree of numerator  $b$  and  $N$  the degree of denominator  $a$ :

$$H(s) = \frac{b(s)}{a(s)} = \frac{b[0] s^{(M)} + b[1] s^{(M-1)} + \dots + b[M]}{a[0] s^{(N)} + a[1] s^{(N-1)} + \dots + a[N]}$$

then the partial-fraction expansion  $H(s)$  is defined as:

$$= \frac{r[0]}{(s-p[0])} + \frac{r[1]}{(s-p[1])} + \dots + \frac{r[-1]}{(s-p[-1])} + k(s)$$

If there are any repeated roots (closer together than *tol*), then  $H(s)$  has terms like:

$$\frac{r[i]}{(s-p[i])} + \frac{r[i+1]}{(s-p[i])**2} + \dots + \frac{r[i+n-1]}{(s-p[i])**n}$$

This function is used for polynomials in positive powers of  $s$  or  $z$ , such as analog filters or digital filters in controls engineering. For negative powers of  $z$  (typical for digital filters in DSP), use `residuez`.

**Parameters**

- b** : array\_like  
Numerator polynomial coefficients.
- a** : array\_like  
Denominator polynomial coefficients.

**Returns**

- r** : ndarray  
Residues.
- p** : ndarray  
Poles.
- k** : ndarray  
Coefficients of the direct polynomial term.

**See also:**

`invres`, `residuez`, `numpy.poly`, `unique_roots`

`scipy.signal.residuez` (*b*, *a*, *tol*=0.001, *rtype*='avg')

Compute partial-fraction expansion of  $b(z) / a(z)$ .

If  $M$  is the degree of numerator  $b$  and  $N$  the degree of denominator  $a$ :

$$H(z) = \frac{b(z)}{a(z)} = \frac{b[0] + b[1] z^{(-1)} + \dots + b[M] z^{(-M)}}{a[0] + a[1] z^{(-1)} + \dots + a[N] z^{(-N)}}$$

then the partial-fraction expansion  $H(z)$  is defined as:

$$= \frac{r[0]}{(1-p[0]z^{(-1)})} + \dots + \frac{r[-1]}{(1-p[-1]z^{(-1)})} + k[0] + k[1]z^{(-1)} \dots$$

If there are any repeated roots (closer than *tol*), then the partial fraction expansion has terms like:

$$\frac{r[i]}{(1-p[i]z^{**(-1)})} + \frac{r[i+1]}{(1-p[i]z^{**(-1)})**2} + \dots + \frac{r[i+n-1]}{(1-p[i]z^{**(-1)})**n}$$

This function is used for polynomials in negative powers of z, such as digital filters in DSP. For positive powers, use *residue*.

**Parameters**

- b** : array\_like  
Numerator polynomial coefficients.
- a** : array\_like  
Denominator polynomial coefficients.

**Returns**

- r** : ndarray  
Residues.
- p** : ndarray  
Poles.
- k** : ndarray  
Coefficients of the direct polynomial term.

**See also:**

*invresz, residue, unique\_roots*

`scipy.signal.invres(r, p, k, tol=0.001, rtype='avg')`  
Compute b(s) and a(s) from partial fraction expansion.

If *M* is the degree of numerator *b* and *N* the degree of denominator *a*:

$$H(s) = \frac{b(s)}{a(s)} = \frac{b[0] s^{** (M)} + b[1] s^{** (M-1)} + \dots + b[M]}{a[0] s^{** (N)} + a[1] s^{** (N-1)} + \dots + a[N]}$$

then the partial-fraction expansion H(s) is defined as:

$$= \frac{r[0]}{(s-p[0])} + \frac{r[1]}{(s-p[1])} + \dots + \frac{r[-1]}{(s-p[-1])} + k(s)$$

If there are any repeated roots (closer together than *tol*), then H(s) has terms like:

$$\frac{r[i]}{(s-p[i])} + \frac{r[i+1]}{(s-p[i])**2} + \dots + \frac{r[i+n-1]}{(s-p[i])**n}$$

This function is used for polynomials in positive powers of s or z, such as analog filters or digital filters in controls engineering. For negative powers of z (typical for digital filters in DSP), use *invresz*.

**Parameters**

- r** : array\_like  
Residues.
- p** : array\_like  
Poles.
- k** : array\_like  
Coefficients of the direct polynomial term.
- tol** : float, optional  
The tolerance for two roots to be considered equal. Default is 1e-3.
- rtype** : { 'max', 'min', 'avg' }, optional  
How to determine the returned root if multiple roots are within *tol* of each other.

- 'max': pick the maximum of those roots.
- 'min': pick the minimum of those roots.

**Returns**

- b** : ndarray  
Numerator polynomial coefficients.
- a** : ndarray  
Denominator polynomial coefficients.

•‘avg’: take the average of those roots.

**See also:**

*residue, invresz, unique\_roots*

`scipy.signal.invresz(r, p, k, tol=0.001, rtype='avg')`  
Compute  $b(z)$  and  $a(z)$  from partial fraction expansion.

If  $M$  is the degree of numerator  $b$  and  $N$  the degree of denominator  $a$ :

$$H(z) = \frac{b(z)}{a(z)} = \frac{b[0] + b[1]z^{-1} + \dots + b[M]z^{-M}}{a[0] + a[1]z^{-1} + \dots + a[N]z^{-N}}$$

then the partial-fraction expansion  $H(z)$  is defined as:

$$= \frac{r[0]}{(1-p[0]z^{-1})} + \dots + \frac{r[-1]}{(1-p[-1]z^{-1})} + k[0] + k[1]z^{-1} \dots$$

If there are any repeated roots (closer than *tol*), then the partial fraction expansion has terms like:

$$\frac{r[i]}{(1-p[i]z^{-1})} + \frac{r[i+1]}{(1-p[i]z^{-1})^2} + \dots + \frac{r[i+n-1]}{(1-p[i]z^{-1})^n}$$

This function is used for polynomials in negative powers of  $z$ , such as digital filters in DSP. For positive powers, use *invres*.

**Parameters**

- r** : array\_like  
Residues.
- p** : array\_like  
Poles.
- k** : array\_like  
Coefficients of the direct polynomial term.
- tol** : float, optional  
The tolerance for two roots to be considered equal. Default is 1e-3.
- rtype** : {‘max’, ‘min’, ‘avg’}, optional  
How to determine the returned root if multiple roots are within *tol* of each other.
  - ‘max’: pick the maximum of those roots.
  - ‘min’: pick the minimum of those roots.
  - ‘avg’: take the average of those roots.

**Returns**

- b** : ndarray  
Numerator polynomial coefficients.
- a** : ndarray  
Denominator polynomial coefficients.

**See also:**

*residuez, unique\_roots, invres*

**exception** `scipy.signal.BadCoefficients`

Warning about badly conditioned filter coefficients

Lower-level filter design functions:

<code>abcd_normalize([A, B, C, D])</code>	Check state-space matrices and ensure they are two-dimensional.
<code>band_stop_obj(wp, ind, passb, stopb, gpass, ...)</code>	Band Stop Objective Function for order minimization.
<code>besselap(N[, norm])</code>	Return (z,p,k) for analog prototype of an Nth-order Bessel filter.
<code>buttap(N)</code>	Return (z,p,k) for analog prototype of Nth-order Butterworth filter.
<code>cheblap(N, rp)</code>	Return (z,p,k) for Nth-order Chebyshev type I analog low-pass filter.
<code>cheb2ap(N, rs)</code>	Return (z,p,k) for Nth-order Chebyshev type I analog low-pass filter.
<code>cmplx_sort(p)</code>	Sort roots based on magnitude.
<code>ellipap(N, rp, rs)</code>	Return (z,p,k) of Nth-order elliptic analog lowpass filter.
<code>lp2bp(b, a[, wo, bw])</code>	Transform a lowpass filter prototype to a bandpass filter.
<code>lp2bs(b, a[, wo, bw])</code>	Transform a lowpass filter prototype to a bandstop filter.
<code>lp2hp(b, a[, wo])</code>	Transform a lowpass filter prototype to a highpass filter.
<code>lp2lp(b, a[, wo])</code>	Transform a lowpass filter prototype to a different frequency.
<code>normalize(b, a)</code>	Normalize numerator/denominator of a continuous-time transfer function.

`scipy.signal.abcd_normalize` (*A=None, B=None, C=None, D=None*)

Check state-space matrices and ensure they are two-dimensional.

If enough information on the system is provided, that is, enough properly-shaped arrays are passed to the function, the missing ones are built from this information, ensuring the correct number of rows and columns. Otherwise a `ValueError` is raised.

**Parameters** **A, B, C, D** : array\_like, optional  
 State-space matrices. All of them are None (missing) by default. See `ss2tf` for format.

**Returns** **A, B, C, D** : array  
 Properly shaped state-space matrices.

**Raises** **ValueError**  
 If not enough information on the system was provided.

`scipy.signal.band_stop_obj` (*wp, ind, passb, stopb, gpass, gstop, type*)

Band Stop Objective Function for order minimization.

Returns the non-integer order for an analog band stop filter.

**Parameters** **wp** : scalar  
 Edge of passband *passb*.

**ind** : int, {0, 1}  
 Index specifying which *passb* edge to vary (0 or 1).

**passb** : ndarray  
 Two element sequence of fixed passband edges.

**stopb** : ndarray  
 Two element sequence of fixed stopband edges.

**gstop** : float  
 Amount of attenuation in stopband in dB.

**gpass** : float  
 Amount of ripple in the passband in dB.

**type** : { 'butter', 'cheby', 'ellip' }

**Returns** **n** : scalar  
 Type of filter.

Filter order (possibly non-integer).

`scipy.signal.besselap` ( $N$ ,  $norm='phase'$ )

Return (z,p,k) for analog prototype of an Nth-order Bessel filter.

**Parameters**  $N$  : int

The order of the filter.

**norm** : { 'phase', 'delay', 'mag' }, optional

Frequency normalization:

**phase** The filter is normalized such that the phase response reaches its midpoint at an angular (e.g. rad/s) cutoff frequency of 1. This happens for both low-pass and high-pass filters, so this is the “phase-matched” case. [R235]

The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of  $Wn$ .

This is the default, and matches MATLAB’s implementation.

**delay** The filter is normalized such that the group delay in the pass-band is 1 (e.g. 1 second). This is the “natural” type obtained by solving Bessel polynomials.

**mag** The filter is normalized such that the gain magnitude is -3 dB at angular frequency 1. This is called “frequency normalization” by Bond. [R230]

New in version 0.18.0.

**Returns**  $z$  : ndarray

Zeros of the transfer function. Is always an empty array.

$p$  : ndarray

Poles of the transfer function.

$k$  : scalar

Gain of the transfer function. For phase-normalized, this is always 1.

**See also:**

**bessel** Filter design function using this prototype

**Notes**

To find the pole locations, approximate starting points are generated [R231] for the zeros of the ordinary Bessel polynomial [R232], then the Aberth-Ehrlich method [R233] [R234] is used on the  $K_v(x)$  Bessel function to calculate more accurate zeros, and these locations are then inverted about the unit circle.

**References**

[R230], [R231], [R232], [R233], [R234], [R235]

`scipy.signal.buttap` ( $N$ )

Return (z,p,k) for analog prototype of Nth-order Butterworth filter.

The filter will have an angular (e.g. rad/s) cutoff frequency of 1.

**See also:**

**butter** Filter design function using this prototype

`scipy.signal.cheblap` ( $N$ ,  $rp$ )

Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.

The returned filter prototype has  $rp$  decibels of ripple in the passband.

The filter’s angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below  $-rp$ .

**See also:**

**cheby1** Filter design function using this prototype

`scipy.signal.cheb2ap` ( $N, rs$ )

Return  $(z,p,k)$  for Nth-order Chebyshev type I analog lowpass filter.

The returned filter prototype has  $rs$  decibels of ripple in the stopband.

The filter's angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first reaches  $-rs$ .

**See also:**

**cheby2** Filter design function using this prototype

`scipy.signal.cmplx_sort` ( $p$ )

Sort roots based on magnitude.

**Parameters** **p** : array\_like

**Returns** **p\_sorted** : ndarray The roots to sort, as a 1-D array.

Sorted roots.

**indx** : ndarray

Array of indices needed to sort the input  $p$ .

`scipy.signal.ellipap` ( $N, rp, rs$ )

Return  $(z,p,k)$  of Nth-order elliptic analog lowpass filter.

The filter is a normalized prototype that has  $rp$  decibels of ripple in the passband and a stopband  $rs$  decibels down.

The filter's angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below  $-rp$ .

**See also:**

**ellip** Filter design function using this prototype

**References**

[R251]

`scipy.signal.lp2bp` ( $b, a, wo=1.0, bw=1.0$ )

Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency  $wo$  and bandwidth  $bw$  from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

`scipy.signal.lp2bs` ( $b, a, wo=1.0, bw=1.0$ )

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency  $wo$  and bandwidth  $bw$  from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

`scipy.signal.lp2hp` ( $b, a, wo=1.0$ )

Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency  $wo$  from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

`scipy.signal.lp2lp` ( $b, a, wo=1.0$ )

Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency  $wo$  from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

`scipy.signal.normalize(b, a)`

Normalize numerator/denominator of a continuous-time transfer function.

If values of  $b$  are too close to 0, they are removed. In that case, a `BadCoefficients` warning is emitted.

<b>Parameters</b>	<b>b: array_like</b>	Numerator of the transfer function. Can be a 2d array to normalize multiple transfer functions.
	<b>a: array_like</b>	Denominator of the transfer function. At most 1d.
<b>Returns</b>	<b>num: array</b>	The numerator of the normalized transfer function. At least a 1d array. A 2d-array if the input <i>num</i> is a 2d array.
	<b>den: 1d-array</b>	The denominator of the normalized transfer function.

#### Notes

Coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.,  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

## 5.20.5 Matlab-style IIR filter design

<code>butter(N, Wn[, btype, analog, output])</code>	Butterworth digital and analog filter design.
<code>buttord(wp, ws, gpass, gstop[, analog])</code>	Butterworth filter order selection.
<code>cheby1(N, rp, Wn[, btype, analog, output])</code>	Chebyshev type I digital and analog filter design.
<code>cheblord(wp, ws, gpass, gstop[, analog])</code>	Chebyshev type I filter order selection.
<code>cheby2(N, rs, Wn[, btype, analog, output])</code>	Chebyshev type II digital and analog filter design.
<code>cheb2ord(wp, ws, gpass, gstop[, analog])</code>	Chebyshev type II filter order selection.
<code>ellip(N, rp, rs, Wn[, btype, analog, output])</code>	Elliptic (Cauer) digital and analog filter design.
<code>ellipord(wp, ws, gpass, gstop[, analog])</code>	Elliptic (Cauer) filter order selection.
<code>bessel(N, Wn[, btype, analog, output, norm])</code>	Bessel/Thomson digital and analog filter design.
<code>iirnotch(w0, Q)</code>	Design second-order IIR notch digital filter.
<code>iirpeak(w0, Q)</code>	Design second-order IIR peak (resonant) digital filter.

`scipy.signal.butter(N, Wn, btype='low', analog=False, output='ba')`

Butterworth digital and analog filter design.

Design an Nth-order digital or analog Butterworth filter and return the filter coefficients.

<b>Parameters</b>	<b>N : int</b>	The order of the filter.
	<b>Wn : array_like</b>	A scalar or length-2 sequence giving the critical frequencies. For a Butterworth filter, this is the point at which the gain drops to $1/\sqrt{2}$ that of the passband (the “-3 dB point”). For digital filters, $Wn$ is normalized from 0 to 1, where 1 is the Nyquist frequency, $\pi$ radians/sample. ( $Wn$ is thus in half-cycles / sample.) For analog filters, $Wn$ is an angular frequency (e.g. rad/s).
	<b>btype : { 'lowpass', 'highpass', 'bandpass', 'bandstop' }, optional</b>	The type of filter. Default is 'lowpass'.
	<b>analog : bool, optional</b>	When True, return an analog filter, otherwise a digital filter is returned.
	<b>output : { 'ba', 'zpk', 'sos' }, optional</b>	

**Returns**

**b, a** : ndarray, ndarray  
 Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.  
 Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

**z, p, k** : ndarray, ndarray, float  
 Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

**sos** : ndarray  
 Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:***butterd, butterap***Notes**

The Butterworth filter has maximally flat frequency response in the passband.

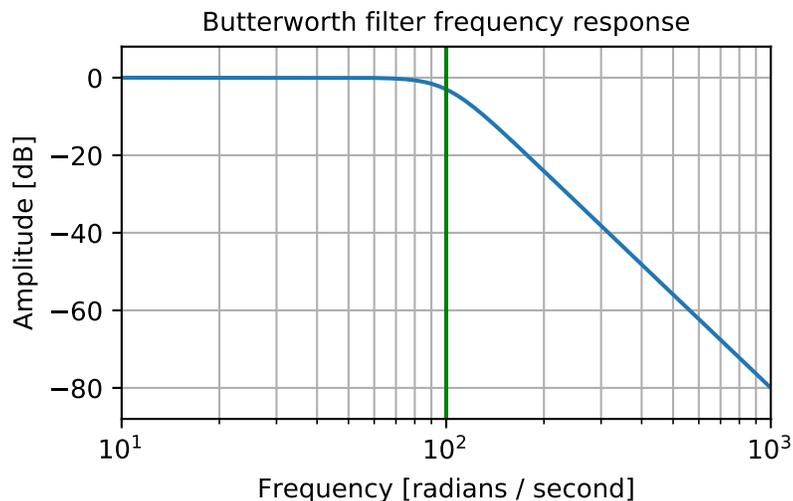

The 'sos' output parameter was added in 0.16.0.

**Examples**

Plot the filter's frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.show()
```

`scipy.signal.buttord` (*wp*, *ws*, *gpass*, *gstop*, *analog=False*)

Butterworth filter order selection.

Return the order of the lowest order digital or analog Butterworth filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

**Parameters**    **wp, ws** : float

Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: *wp* = 0.2, *ws* = 0.3
- Highpass: *wp* = 0.3, *ws* = 0.2
- Bandpass: *wp* = [0.2, 0.5], *ws* = [0.1, 0.6]
- Bandstop: *wp* = [0.1, 0.6], *ws* = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g. rad/s).

**gpass** : float

The maximum loss in the passband (dB).

**gstop** : float

The minimum attenuation in the stopband (dB).

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

**Returns**

**ord** : int

The lowest order for a Butterworth filter which meets specs.

**wn** : ndarray or float

The Butterworth natural frequency (i.e. the “3dB frequency”). Should be used with *butter* to give filter results.

**See also:**

**butter**    Filter design using order and critical points

**cheb1ord**    Find order and critical points from passband and stopband spec

*cheb2ord*, *ellipord*

**iirfilter**    General filter design using order and critical frequencies

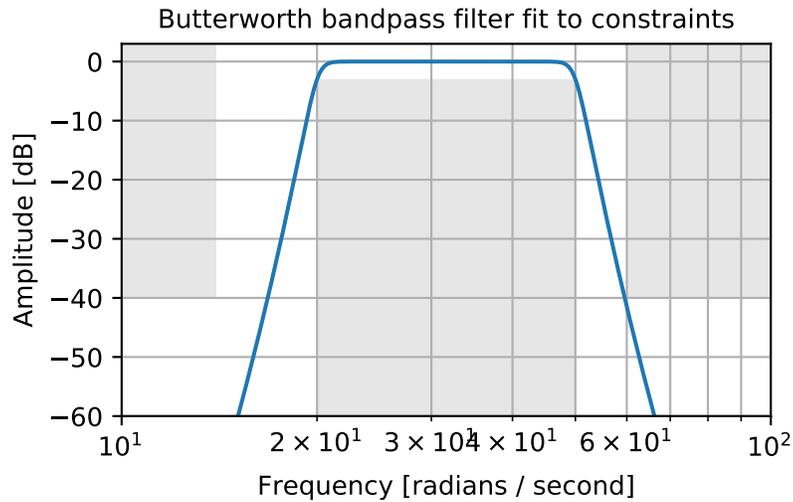

**iirdesign**    General filter design using passband and stopband spec

**Examples**

Design an analog bandpass filter with passband within 3 dB from 20 to 50 rad/s, while rejecting at least -40 dB below 14 and above 60 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> N, Wn = signal.buttord([20, 50], [14, 60], 3, 40, True)
>>> b, a = signal.butter(N, Wn, 'band', True)
>>> w, h = signal.freqs(b, a, np.logspace(1, 2, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth bandpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([1, 14, 14, 1], [-40, -40, 99, 99], '0.9', lw=0) # stop
>>> plt.fill([20, 20, 50, 50], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.fill([60, 60, 1e9, 1e9], [99, -40, -40, 99], '0.9', lw=0) # stop
>>> plt.axis([10, 100, -60, 3])
>>> plt.show()
```

`scipy.signal.cheby1(N, rp, Wn, btype='low', analog=False, output='ba')`  
Chebyshev type I digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type I filter and return the filter coefficients.

**Parameters**

- N** : int  
The order of the filter.
- rp** : float  
The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
- Wn** : array\_like  
A scalar or length-2 sequence giving the critical frequencies. For Type I filters, this is the point in the transition band at which the gain first drops below  $-rp$ . For digital filters,  $Wn$  is normalized from 0 to 1, where 1 is the Nyquist frequency,  $\pi$  radians/sample. ( $Wn$  is thus in half-cycles / sample.) For analog filters,  $Wn$  is an angular frequency (e.g. rad/s).
- btype** : {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional  
The type of filter. Default is 'lowpass'.
- analog** : bool, optional  
When True, return an analog filter, otherwise a digital filter is returned.
- output** : {'ba', 'zpk', 'sos'}, optional  
Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

- b, a** : ndarray, ndarray  
Numerator ( $b$ ) and denominator ( $a$ ) polynomials of the IIR filter. Only returned if `output='ba'`.
- z, p, k** : ndarray, ndarray, float  
Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.
- sos** : ndarray  
Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:**

`cheblord`, `cheblap`

### Notes

The Chebyshev type I filter maximizes the rate of cutoff between the frequency response's passband and stopband, at the expense of ripple in the passband and increased ringing in the step response.

Type I filters roll off faster than Type II (*cheby2*), but Type II filters do not have any ripple in the passband.

The equiripple passband has  $N$  maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or  $-rp$  dB for even-order filters.

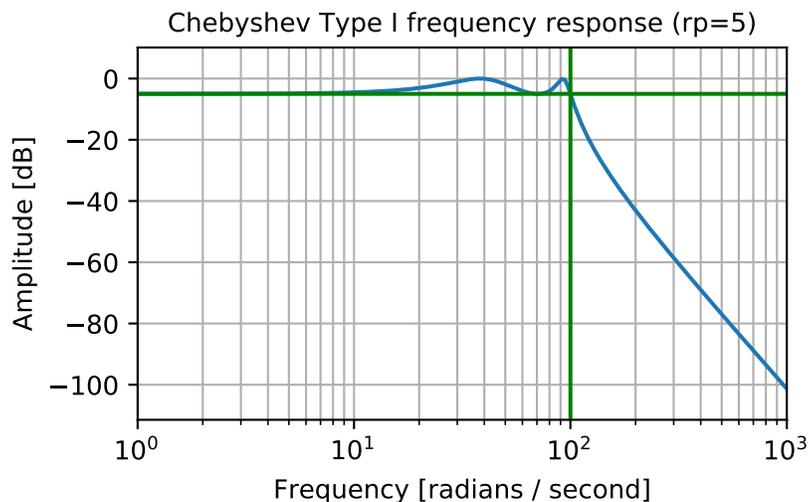

The 'sos' output parameter was added in 0.16.0.

### Examples

Plot the filter's frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby1(4, 5, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type I frequency response (rp=5)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

`scipy.signal.cheblord` (*wp, ws, gpass, gstop, analog=False*)  
Chebyshev type I filter order selection.

Return the order of the lowest order digital or analog Chebyshev Type I filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

**Parameters** `wp, ws` : float

Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: *wp* = 0.2, *ws* = 0.3
- Highpass: *wp* = 0.3, *ws* = 0.2
- Bandpass: *wp* = [0.2, 0.5], *ws* = [0.1, 0.6]
- Bandstop: *wp* = [0.1, 0.6], *ws* = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g. rad/s).

**gpass** : float

The maximum loss in the passband (dB).

**gstop** : float

The minimum attenuation in the stopband (dB).

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

**Returns**

**ord** : int

The lowest order for a Chebyshev type I filter that meets specs.

**wn** : ndarray or float

The Chebyshev natural frequency (the “3dB frequency”) for use with *cheby1* to give filter results.

**See also:**

**cheby1** Filter design using order and critical points

**buttord** Find order and critical points from passband and stopband spec

*cheb2ord*, *ellipord*

**iirfilter** General filter design using order and critical frequencies

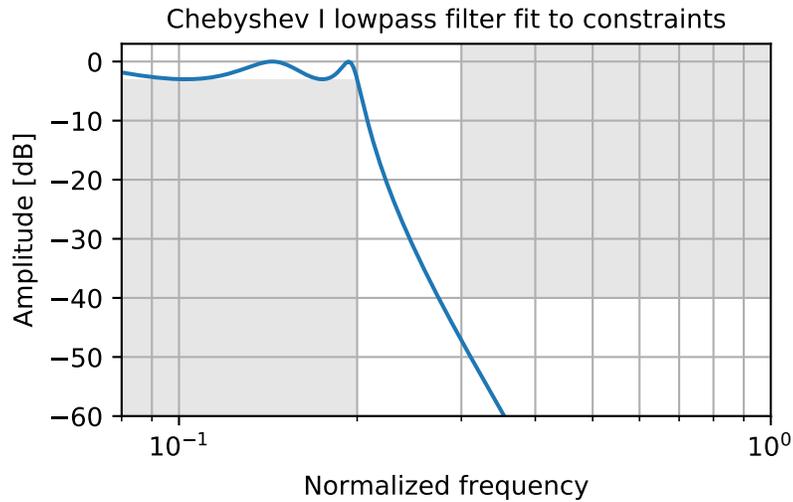

**iirdesign** General filter design using passband and stopband spec

**Examples**

Design a digital lowpass filter such that the passband is within 3 dB up to  $0.2 \cdot (fs/2)$ , while rejecting at least -40 dB above  $0.3 \cdot (fs/2)$ . Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> N, Wn = signal.cheblord(0.2, 0.3, 3, 40)
>>> b, a = signal.cheby1(N, 3, Wn, 'low')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev I lowpass filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([0.01, 0.2, 0.2, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([0.3, 0.3, 2, 2], [9, -40, -40, 9], '0.9', lw=0) # pass
>>> plt.axis([0.08, 1, -60, 3])
>>> plt.show()
```

`scipy.signal.cheby2(N, rs, Wn, btype='low', analog=False, output='ba')`  
 Chebyshev type II digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type II filter and return the filter coefficients.

**Parameters**

- N** : int  
The order of the filter.
- rs** : float  
The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- Wn** : array\_like  
A scalar or length-2 sequence giving the critical frequencies. For Type II filters, this is the point in the transition band at which the gain first reaches  $-rs$ . For digital filters,  $Wn$  is normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. ( $Wn$  is thus in half-cycles / sample.) For analog filters,  $Wn$  is an angular frequency (e.g. rad/s).
- btype** : {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional  
The type of filter. Default is 'lowpass'.
- analog** : bool, optional  
When True, return an analog filter, otherwise a digital filter is returned.
- output** : {'ba', 'zpk', 'sos'}, optional  
Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

- b, a** : ndarray, ndarray  
Numerator ( $b$ ) and denominator ( $a$ ) polynomials of the IIR filter. Only returned if `output='ba'`.
- z, p, k** : ndarray, ndarray, float  
Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.
- sos** : ndarray  
Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:**

`cheb2ord`, `cheb2ap`

**Notes**

The Chebyshev type II filter maximizes the rate of cutoff between the frequency response's passband and stopband, at the expense of ripple in the stopband and increased ringing in the step response.

Type II filters do not roll off as fast as Type I (*cheby1*).

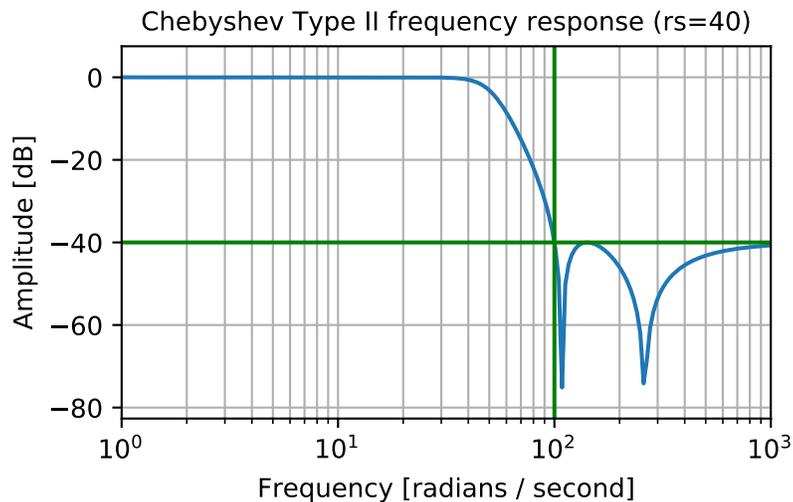

The 'sos' output parameter was added in 0.16.0.

**Examples**

Plot the filter's frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.cheby2(4, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type II frequency response (rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-40, color='green') # rs
>>> plt.show()
```

`scipy.signal.cheb2ord` (*wp, ws, gpass, gstop, analog=False*)

Chebyshev type II filter order selection.

Return the order of the lowest order digital or analog Chebyshev Type II filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

**Parameters** `wp, ws` : float

Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: `wp = 0.2, ws = 0.3`
- Highpass: `wp = 0.3, ws = 0.2`

- Bandpass:  $w_p = [0.2, 0.5]$ ,  $w_s = [0.1, 0.6]$
- Bandstop:  $w_p = [0.1, 0.6]$ ,  $w_s = [0.2, 0.5]$

For analog filters,  $w_p$  and  $w_s$  are angular frequencies (e.g. rad/s).

**gpass** : float

The maximum loss in the passband (dB).

**gstop** : float

The minimum attenuation in the stopband (dB).

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

**Returns**

**ord** : int

The lowest order for a Chebyshev type II filter that meets specs.

**wn** : ndarray or float

The Chebyshev natural frequency (the “3dB frequency”) for use with *cheby2* to give filter results.

**See also:**

**cheby2** Filter design using order and critical points

**buttord** Find order and critical points from passband and stopband spec

*cheblord*, *ellipord*

**iirfilter** General filter design using order and critical frequencies

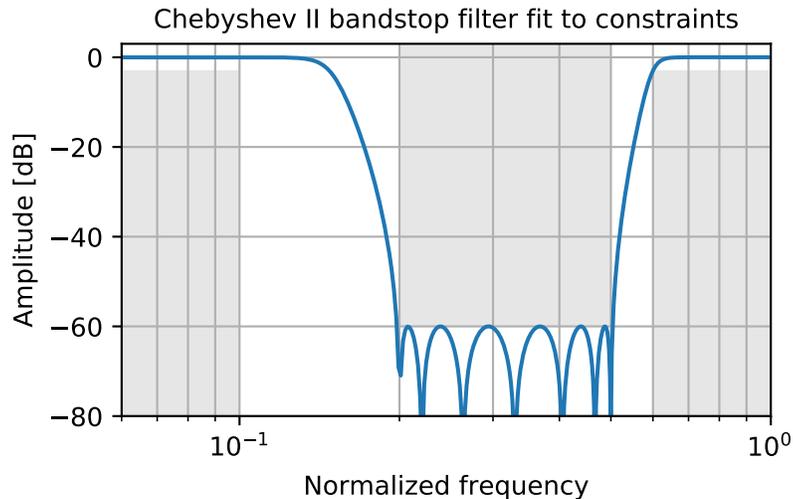

**iirdesign** General filter design using passband and stopband spec

**Examples**

Design a digital bandstop filter which rejects -60 dB from  $0.2*(fs/2)$  to  $0.5*(fs/2)$ , while staying within 3 dB below  $0.1*(fs/2)$  or above  $0.6*(fs/2)$ . Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> N, Wn = signal.cheb2ord([0.1, 0.6], [0.2, 0.5], 3, 60)
>>> b, a = signal.cheby2(N, 60, Wn, 'stop')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev II bandstop filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, .1, .1, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([.2, .2, .5, .5], [ 9, -60, -60,  9], '0.9', lw=0) # pass
>>> plt.fill([.6, .6, 2, 2], [-99, -3, -3, -99], '0.9', lw=0) # stop
>>> plt.axis([0.06, 1, -80, 3])
>>> plt.show()
```

`scipy.signal.ellip` ( $N$ ,  $rp$ ,  $rs$ ,  $Wn$ ,  $btype='low'$ ,  $analog=False$ ,  $output='ba'$ )  
 Elliptic (Cauer) digital and analog filter design.

Design an  $N$ th-order digital or analog elliptic filter and return the filter coefficients.

**Parameters**

- $N$**  : int  
The order of the filter.
- $rp$**  : float  
The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
- $rs$**  : float  
The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- $Wn$**  : array\_like  
A scalar or length-2 sequence giving the critical frequencies. For elliptic filters, this is the point in the transition band at which the gain first drops below  $-rp$ . For digital filters,  $Wn$  is normalized from 0 to 1, where 1 is the Nyquist frequency,  $\pi$  radians/sample. ( $Wn$  is thus in half-cycles / sample.) For analog filters,  $Wn$  is an angular frequency (e.g. rad/s).
- $btype$**  : {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional  
The type of filter. Default is 'lowpass'.
- $analog$**  : bool, optional  
When True, return an analog filter, otherwise a digital filter is returned.
- $output$**  : {'ba', 'zpk', 'sos'}, optional  
Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

- $b$ ,  $a$**  : ndarray, ndarray  
Numerator ( $b$ ) and denominator ( $a$ ) polynomials of the IIR filter. Only returned if `output='ba'`.
- $z$ ,  $p$ ,  $k$**  : ndarray, ndarray, float  
Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.
- $sos$**  : ndarray  
Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

See also:

*ellipord, ellipap*

### Notes

Also known as Cauer or Zolotarev filters, the elliptical filter maximizes the rate of transition between the frequency response's passband and stopband, at the expense of ripple in both, and increased ringing in the step response.

As *rp* approaches 0, the elliptical filter becomes a Chebyshev type II filter (*cheby2*). As *rs* approaches 0, it becomes a Chebyshev type I filter (*cheby1*). As both approach 0, it becomes a Butterworth filter (*butter*).

The equiripple passband has *N* maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or -*rp* dB for even-order filters.

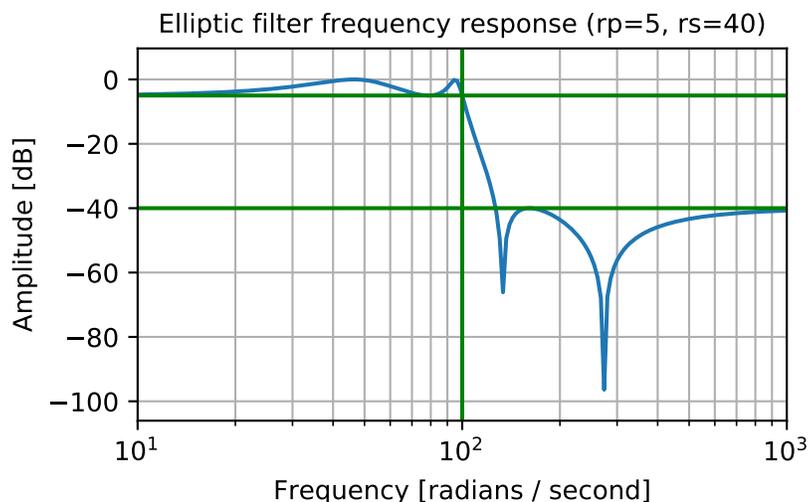

The 'sos' output parameter was added in 0.16.0.

### Examples

Plot the filter's frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.ellip(4, 5, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptic filter frequency response (rp=5, rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-40, color='green') # rs
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

`scipy.signal.ellipord` (*wp, ws, gpass, gstop, analog=False*)  
Elliptic (Cauer) filter order selection.

Return the order of the lowest order digital or analog elliptic filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

**Parameters**

**wp, ws** : float  
 Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: *wp* = 0.2, *ws* = 0.3
- Highpass: *wp* = 0.3, *ws* = 0.2
- Bandpass: *wp* = [0.2, 0.5], *ws* = [0.1, 0.6]
- Bandstop: *wp* = [0.1, 0.6], *ws* = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g. rad/s).

**gpass** : float  
 The maximum loss in the passband (dB).

**gstop** : float  
 The minimum attenuation in the stopband (dB).

**analog** : bool, optional  
 When True, return an analog filter, otherwise a digital filter is returned.

**Returns**

**ord** : int  
 The lowest order for an Elliptic (Cauer) filter that meets specs.

**wn** : ndarray or float  
 The Chebyshev natural frequency (the “3dB frequency”) for use with *ellip* to give filter results.

**See also:**

**ellip** Filter design using order and critical points  
**buttord** Find order and critical points from passband and stopband spec

*cheblord*, *cheb2ord*

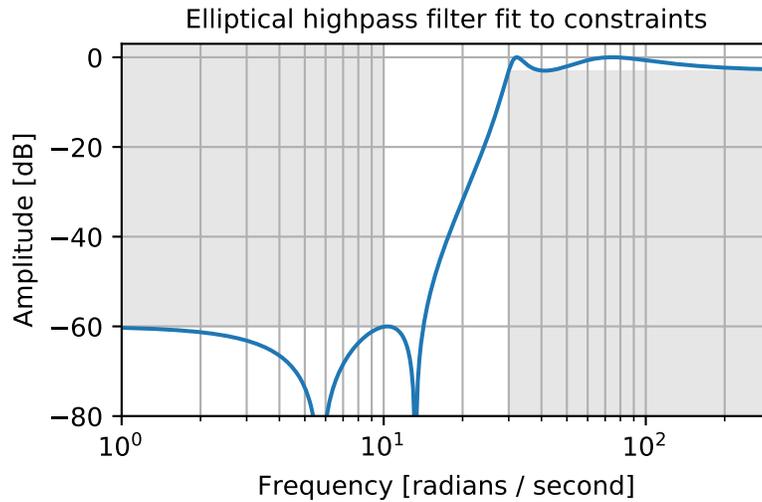

**iirfilter** General filter design using order and critical frequencies  
**iirdesign** General filter design using passband and stopband spec

### Examples

Design an analog highpass filter such that the passband is within 3 dB above 30 rad/s, while rejecting -60 dB at 10 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.ellipord(30, 10, 3, 60, True)
>>> b, a = signal.ellip(N, 3, 60, Wn, 'high', True)
>>> w, h = signal.freqs(b, a, np.logspace(0, 3, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptical highpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.1, 10, 10, .1], [1e4, 1e4, -60, -60], '0.9', lw=0) # stop
>>> plt.fill([30, 30, 1e9, 1e9], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.axis([1, 300, -80, 3])
>>> plt.show()
```

`scipy.signal.bessel` ( $N$ ,  $Wn$ ,  $btype='low'$ ,  $analog=False$ ,  $output='ba'$ ,  $norm='phase'$ )  
Bessel/Thomson digital and analog filter design.

Design an  $N$ th-order digital or analog Bessel filter and return the filter coefficients.

**Parameters**  $N$  : int

The order of the filter.

$Wn$  : array\_like

A scalar or length-2 sequence giving the critical frequencies (defined by the *norm* parameter). For analog filters,  $Wn$  is an angular frequency (e.g. rad/s). For digital filters,  $Wn$  is normalized from 0 to 1, where 1 is the Nyquist frequency,  $\pi$  radians/sample. ( $Wn$  is thus in half-cycles / sample.)

**btype** : {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional

The type of filter. Default is 'lowpass'.

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned. (See Notes.)

**output** : {'ba', 'zpk', 'sos'}, optional

Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**norm** : {'phase', 'delay', 'mag'}, optional

Critical frequency normalization:

**phase**

The filter is normalized such that the phase response reaches its midpoint at angular (e.g. rad/s) frequency  $Wn$ . This happens for both low-pass and high-pass filters, so this is the "phase-matched" case.

The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of  $Wn$ .

This is the default, and matches MATLAB's implementation.

**delay**

The filter is normalized such that the group delay in the passband is  $1/Wn$  (e.g. seconds). This is the "natural" type obtained by solving Bessel polynomials.

**mag**

The filter is normalized such that the gain magnitude is -3 dB at angular frequency  $Wn$ .

**Returns**  $b, a$  : ndarray, ndarray New in version 0.18.0.

Numerator ( $b$ ) and denominator ( $a$ ) polynomials of the IIR filter. Only returned if `output='ba'`.

**z, p, k** : ndarray, ndarray, float  
Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

**sos** : ndarray  
Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

### Notes

Also known as a Thomson filter, the analog Bessel filter has maximally flat group delay and maximally linear phase response, with very little ringing in the step response. [R229]

The Bessel is inherently an analog filter. This function generates digital Bessel filters using the bilinear transform, which does not preserve the phase response of the analog filter. As such, it is only approximately correct at frequencies below about  $fs/4$ . To get maximally-flat group delay at higher frequencies, the analog Bessel filter must be transformed using phase-preserving techniques.

See `besselap` for implementation details and references.

The `'sos'` output parameter was added in 0.16.0.

### References

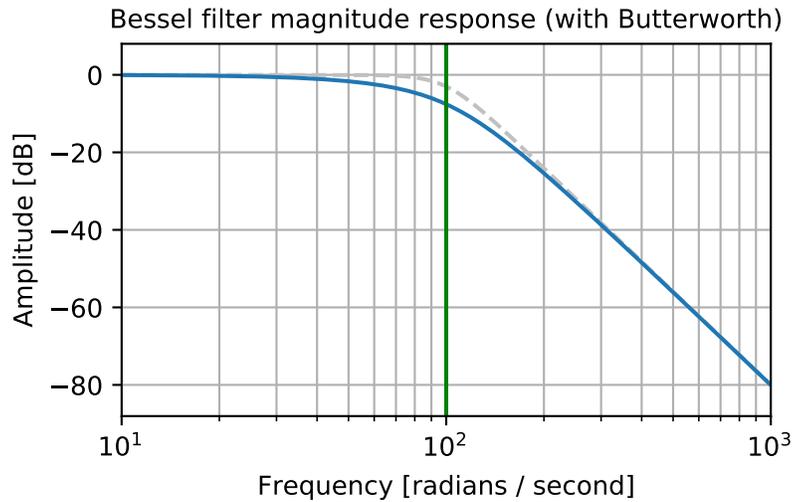

[R229]

### Examples

Plot the phase-normalized frequency response, showing the relationship to the Butterworth's cutoff frequency (green):

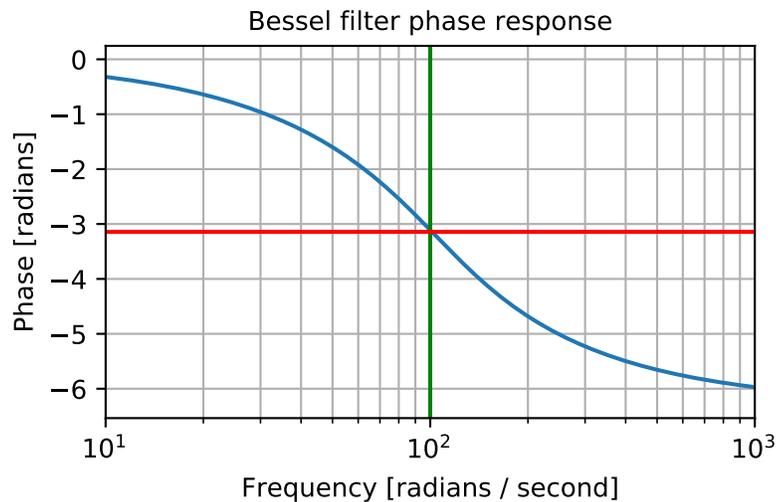

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)), color='silver', ls='dashed')
>>> b, a = signal.bessel(4, 100, 'low', analog=True, norm='phase')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.title('Bessel filter magnitude response (with Butterworth)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.show()
```

and the phase midpoint:

```
>>> plt.figure()
>>> plt.semilogx(w, np.unwrap(np.angle(h)))
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-np.pi, color='red') # phase midpoint
>>> plt.title('Bessel filter phase response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Phase [radians]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```

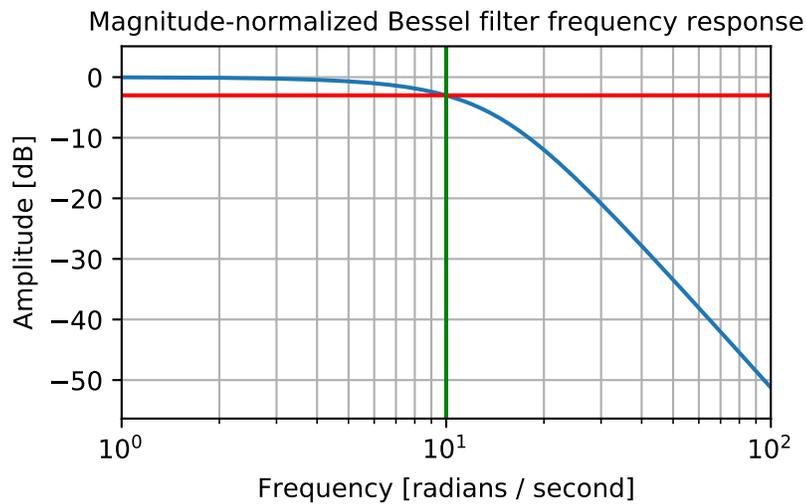

Plot the magnitude-normalized frequency response, showing the -3 dB cutoff:

```
>>> b, a = signal.bessel(3, 10, 'low', analog=True, norm='mag')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
```

```

>>> plt.axhline(-3, color='red') # -3 dB magnitude
>>> plt.axvline(10, color='green') # cutoff frequency
>>> plt.title('Magnitude-normalized Bessel filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()

```

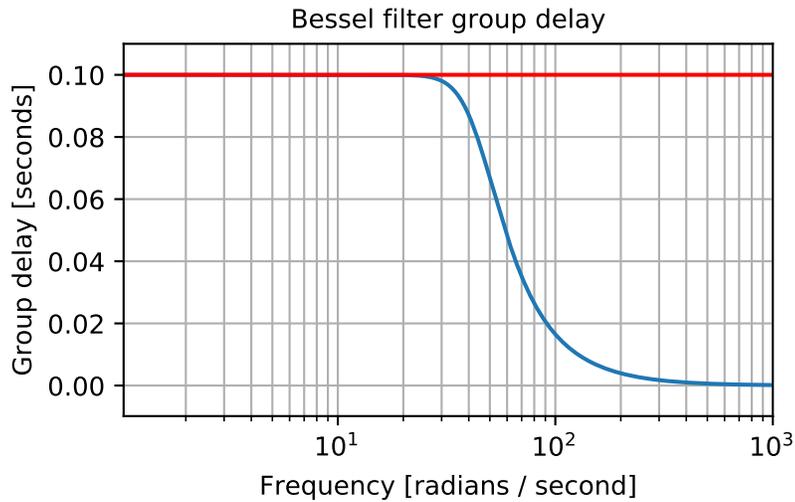

Plot the delay-normalized filter, showing the maximally-flat group delay at 0.1 seconds:

```

>>> b, a = signal.bessel(5, 1/0.1, 'low', analog=True, norm='delay')
>>> w, h = signal.freqs(b, a)
>>> plt.figure()
>>> plt.semilogx(w[1:], -np.diff(np.unwrap(np.angle(h)))/np.diff(w))
>>> plt.axhline(0.1, color='red') # 0.1 seconds group delay
>>> plt.title('Bessel filter group delay')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Group delay [seconds]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()

```

`scipy.signal.iirnotch(w0, Q)`

Design second-order IIR notch digital filter.

A notch filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.

**Parameters** **w0** : float

Normalized frequency to remove from a signal. It is a scalar that must satisfy  $0 < w0 < 1$ , with  $w0 = 1$  corresponding to half of the sampling frequency.

**Q** : float

Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth  $bw$  relative to its center frequency,  $Q = w0/bw$ .

**Returns**

**b, a** : ndarray, ndarray  
 Numerator (b) and denominator (a) polynomials of the IIR filter.

**See also:**

`iirpeak`

**Notes**

**References**

[R275]

**Examples**

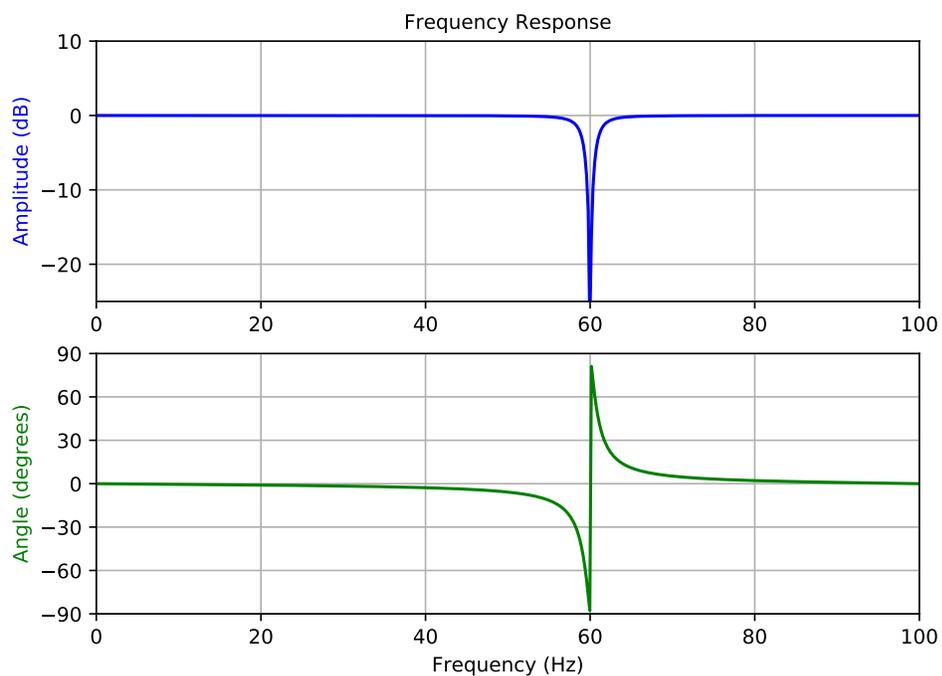

Design and plot filter to remove the 60Hz component from a signal sampled at 200Hz, using a quality factor  $Q = 30$

```
>>> from scipy import signal
>>> import numpy as np
>>> import matplotlib.pyplot as plt
```

```
>>> fs = 200.0 # Sample frequency (Hz)
>>> f0 = 60.0 # Frequency to be removed from signal (Hz)
>>> Q = 30.0 # Quality factor
>>> w0 = f0/(fs/2) # Normalized Frequency
```

```
>>> # Design notch filter
>>> b, a = signal.iirnotch(w0, Q)
```

```
>>> # Frequency response
>>> w, h = signal.freqz(b, a)
>>> # Generate frequency axis
>>> freq = w*fs/(2*np.pi)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-25, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 100])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

`scipy.signal.iirpeak(w0, Q)`  
Design second-order IIR peak (resonant) digital filter.

A peak filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a narrow frequency band.

<b>Parameters</b>	<b>w0</b> : float	Normalized frequency to be retained in a signal. It is a scalar that must satisfy $0 < w0 < 1$ , with $w0 = 1$ corresponding to half of the sampling frequency.
	<b>Q</b> : float	Quality factor. Dimensionless parameter that characterizes peak filter -3 dB bandwidth $bw$ relative to its center frequency, $Q = w0/bw$ .
<b>Returns</b>	<b>b, a</b> : ndarray, ndarray	Numerator (b) and denominator (a) polynomials of the IIR filter.

**See also:**

`iirnotch`

**Notes**

**References**

[R276]

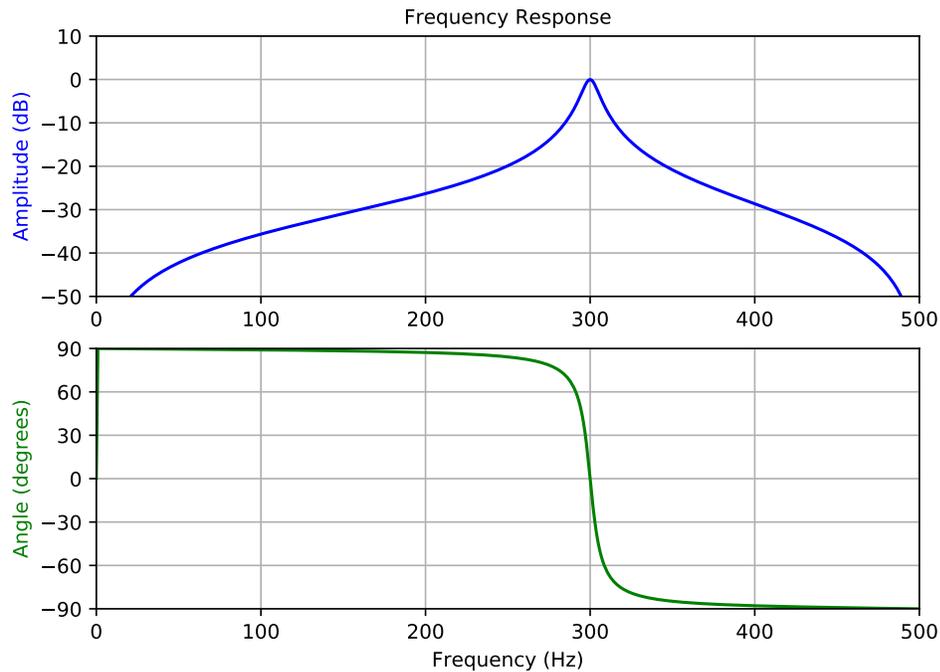

**Examples**

Design and plot filter to remove the frequencies other than the 300Hz component from a signal sampled at 1000Hz, using a quality factor  $Q = 30$

```
>>> from scipy import signal
>>> import numpy as np
>>> import matplotlib.pyplot as plt
```

```
>>> fs = 1000.0 # Sample frequency (Hz)
>>> f0 = 300.0 # Frequency to be retained (Hz)
>>> Q = 30.0 # Quality factor
>>> w0 = f0/(fs/2) # Normalized Frequency
>>> # Design peak filter
>>> b, a = signal.iirpeak(w0, Q)
```

```
>>> # Frequency response
>>> w, h = signal.freqz(b, a)
>>> # Generate frequency axis
>>> freq = w*fs/(2*np.pi)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 500])
>>> ax[0].set_ylim([-50, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 500])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

## 5.20.6 Continuous-Time Linear Systems

<code>lti(*system)</code>	Continuous-time linear time invariant system base class.
<code>StateSpace(*system, **kwargs)</code>	Linear Time Invariant system in state-space form.
<code>TransferFunction(*system, **kwargs)</code>	Linear Time Invariant system class in transfer function form.
<code>ZerosPolesGain(*system, **kwargs)</code>	Linear Time Invariant system class in zeros, poles, gain form.
<code>lsim(system, U, T[, X0, interp])</code>	Simulate output of a continuous-time linear system.
<code>lsim2(system[, U, T, X0])</code>	Simulate output of a continuous-time linear system, by using the ODE solver <code>scipy.integrate.odeint</code> .
<code>impulse(system[, X0, T, N])</code>	Impulse response of continuous-time system.
<code>impulse2(system[, X0, T, N])</code>	Impulse response of a single-input, continuous-time linear system.
<code>step(system[, X0, T, N])</code>	Step response of continuous-time system.
<code>step2(system[, X0, T, N])</code>	Step response of continuous-time system.
<code>freqresp(system[, w, n])</code>	Calculate the frequency response of a continuous-time system.
<code>bode(system[, w, n])</code>	Calculate Bode magnitude and phase data of a continuous-time system.

**class** `scipy.signal.lti` (\*system)  
 Continuous-time linear time invariant system base class.

**Parameters** \*system : arguments

The `lti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding continuous-time subclass that is created:

- 2: `TransferFunction`: (numerator, denominator)
- 3: `ZerosPolesGain`: (zeros, poles, gain)
- 4: `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

**See also:**

`ZerosPolesGain`, `StateSpace`, `TransferFunction`, `dlti`

**Notes**

`lti` instances do not exist directly. Instead, `lti` creates an instance of one of its subclasses: `StateSpace`, `TransferFunction` or `ZerosPolesGain`.

If (numerator, denominator) is passed in for \*system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.,  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

Changing the value of properties that are not directly part of the current system representation (such as the zeros of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

**Examples**

```
>>> from scipy import signal
```

```
>>> signal.lti(1, 2, 3, 4)
StateSpaceContinuous(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: None
)
```

```
>>> signal.lti([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
array([1, 2]),
array([3, 4]),
5,
dt: None
)
```

```
>>> signal.lti([3, 4], [1, 2])
TransferFunctionContinuous(
array([ 3.,  4.]),
array([ 1.,  2.]),
dt: None
)
```

*Attributes*

<i>dt</i>	Return the sampling time of the system, <i>None</i> for <i>lti</i> systems.
<i>poles</i>	Poles of the system.
<i>zeros</i>	Zeros of the system.

`lti.dt`  
Return the sampling time of the system, *None* for *lti* systems.

`lti.poles`  
Poles of the system.

`lti.zeros`  
Zeros of the system.

### Methods

<code>bode([w, n])</code>	Calculate Bode magnitude and phase data of a continuous-time system.
<code>freqresp([w, n])</code>	Calculate the frequency response of a continuous-time system.
<code>impulse([X0, T, N])</code>	Return the impulse response of a continuous-time system.
<code>output(U, T[, X0])</code>	Return the response of a continuous-time system to input <i>U</i> .
<code>step([X0, T, N])</code>	Return the step response of a continuous-time system.
<code>to_discrete(dt[, method, alpha])</code>	Return a discretized version of the current system.

`lti.bode (w=None, n=100)`  
Calculate Bode magnitude and phase data of a continuous-time system.

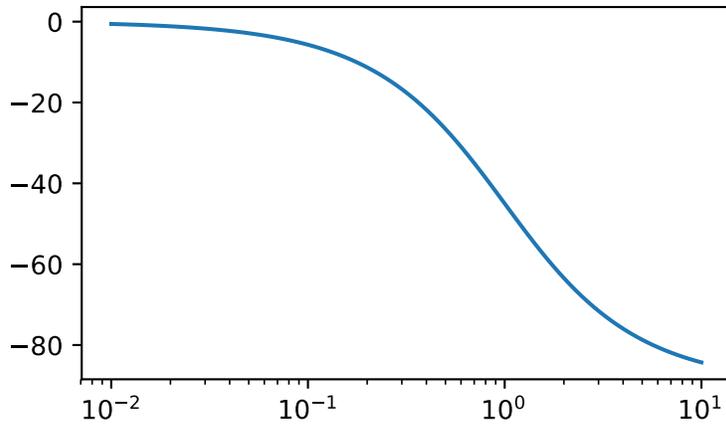

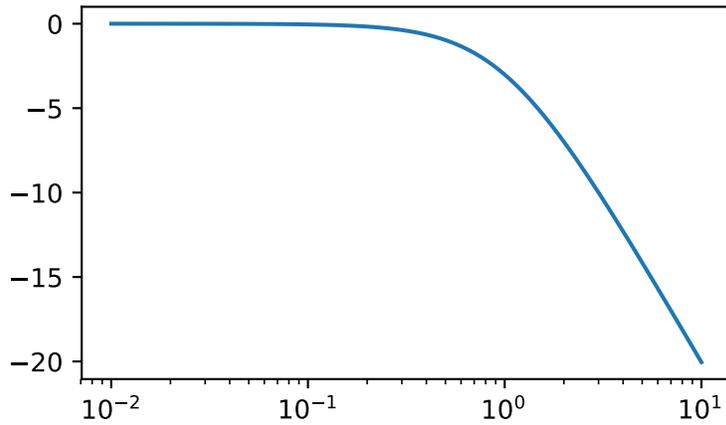

Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See *bode* for details.

### Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = sys.bode()
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag)    # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase) # Bode phase plot
>>> plt.show()
```

`lti.freqresp` (*w=None, n=10000*)

Calculate the frequency response of a continuous-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See *freqresp* for details.

`lti.impulse` (*X0=None, T=None, N=None*)

Return the impulse response of a continuous-time system. See *impulse* for details.

`lti.output` (*U, T, X0=None*)

Return the response of a continuous-time system to input *U*. See *lsim* for details.

`lti.step` (*X0=None, T=None, N=None*)

Return the step response of a continuous-time system. See *step* for details.

`lti.to_discrete` (*dt, method='zoh', alpha=None*)

Return a discretized version of the current system.

Parameters: See *cont2discrete* for details.

**Returns** sys: instance of *dlti*

**class** `scipy.signal.StateSpace` (\*system, \*\*kwargs)  
Linear Time Invariant system in state-space form.

Represents the system as the continuous-time, first order differential equation  $\dot{x} = Ax + Bu$  or the discrete-time difference equation  $x[k+1] = Ax[k] + Bu[k]$ . *StateSpace* systems inherit additional functionality from the *lti*, respectively the *dlti* classes, depending on which system representation is used.

**Parameters** \*system: arguments

The *StateSpace* class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:

- 1: *lti* or *dlti* system: (*StateSpace*,
- TransferFunction* or *ZerosPolesGain*)
- 4: array\_like: (A, B, C, D)

**dt: float, optional**

Sampling time [s] of the discrete-time systems. Defaults to *None* (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

*TransferFunction*, *ZerosPolesGain*, *lti*, *dlti*, *ss2zpk*, *ss2tf*, *zpk2sos*

**Notes**

Changing the value of properties that are not part of the *StateSpace* system representation (such as *zeros* or *poles*) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

**Examples**

```
>>> from scipy import signal
```

```
>>> a = np.array([[0, 1], [0, 0]])
>>> b = np.array([[0], [1]])
>>> c = np.array([[1, 0]])
>>> d = np.array([[0]])
```

```
>>> sys = signal.StateSpace(a, b, c, d)
>>> print(sys)
StateSpaceContinuous(
array([[0, 1],
       [0, 0]]),
array([[0],
       [1]]),
array([[1, 0]]),
array([[0]]),
dt: None
)
```

```
>>> sys.to_discrete(0.1)
StateSpaceDiscrete(
array([[ 1. ,  0.1],
       [ 0. ,  1. ]]),
array([[ 0.005],
       [ 0.1  ]]),
array([[1, 0]]),
```

```
array([[0]]),
dt: 0.1
)
```

```
>>> a = np.array([[1, 0.1], [0, 1]])
>>> b = np.array([[0.005], [0.1]])
```

```
>>> signal.StateSpace(a, b, c, d, dt=0.1)
StateSpaceDiscrete(
array([[ 1. ,  0.1],
       [ 0. ,  1. ]]),
array([[ 0.005],
       [ 0.1 ]]),
array([[1, 0]]),
array([[0]]),
dt: 0.1
)
```

**Attributes**

<i>A</i>	State matrix of the <i>StateSpace</i> system.
<i>B</i>	Input matrix of the <i>StateSpace</i> system.
<i>C</i>	Output matrix of the <i>StateSpace</i> system.
<i>D</i>	Feedthrough matrix of the <i>StateSpace</i> system.
<i>dt</i>	Return the sampling time of the system, <i>None</i> for <i>lti</i> systems.
<i>poles</i>	Poles of the system.
<i>zeros</i>	Zeros of the system.

**StateSpace.A**  
State matrix of the *StateSpace* system.

**StateSpace.B**  
Input matrix of the *StateSpace* system.

**StateSpace.C**  
Output matrix of the *StateSpace* system.

**StateSpace.D**  
Feedthrough matrix of the *StateSpace* system.

**StateSpace.dt**  
Return the sampling time of the system, *None* for *lti* systems.

**StateSpace.poles**  
Poles of the system.

**StateSpace.zeros**  
Zeros of the system.

**Methods**

<i>to_ss()</i>	Return a copy of the current <i>StateSpace</i> system.
<i>to_tf(**kwargs)</i>	Convert system representation to <i>TransferFunction</i> .

Continued on next page

Table 5.148 – continued from previous page

<code>to_zpk(**kwargs)</code>	Convert system representation to <i>ZerosPolesGain</i> .
<code>StateSpace.to_ss()</code>	Return a copy of the current <i>StateSpace</i> system.
<b>Returns</b>	<b>sys</b> : instance of <i>StateSpace</i> The current system (copy)
<code>StateSpace.to_tf(**kwargs)</code>	Convert system representation to <i>TransferFunction</i> .
<b>Parameters</b>	<b>kwargs</b> : dict, optional Additional keywords passed to <i>ss2zpk</i>
<b>Returns</b>	<b>sys</b> : instance of <i>TransferFunction</i> Transfer function of the current system
<code>StateSpace.to_zpk(**kwargs)</code>	Convert system representation to <i>ZerosPolesGain</i> .
<b>Parameters</b>	<b>kwargs</b> : dict, optional Additional keywords passed to <i>ss2zpk</i>
<b>Returns</b>	<b>sys</b> : instance of <i>ZerosPolesGain</i> Zeros, poles, gain representation of the current system
<b>class</b> <code>scipy.signal.TransferFunction(*system, **kwargs)</code>	Linear Time Invariant system class in transfer function form.
	Represents the system as the continuous-time transfer function $H(s) = \sum_{i=0}^N b[N-i]s^i / \sum_{j=0}^M a[M-j]s^j$ or the discrete-time transfer function $H(z) = \sum_{i=0}^N b[N-i]z^i / \sum_{j=0}^M a[M-j]z^j$ , where <i>b</i> are elements of the numerator <i>num</i> , <i>a</i> are elements of the denominator <i>den</i> , and $N == \text{len}(b) - 1, M == \text{len}(a) - 1$ . <i>TransferFunction</i> systems inherit additional functionality from the <i>lti</i> , respectively the <i>dlti</i> classes, depending on which system representation is used.
<b>Parameters</b>	<b>*system: arguments</b> The <i>TransferFunction</i> class can be instantiated with 1 or 2 arguments. The following gives the number of input arguments and their interpretation: •1: <i>lti</i> or <i>dlti</i> system: ( <i>StateSpace</i> , <i>TransferFunction</i> or <i>ZerosPolesGain</i> ) •2: array_like: (numerator, denominator)
	<b>dt: float, optional</b> Sampling time [s] of the discrete-time systems. Defaults to <i>None</i> (continuous-time). Must be specified as a keyword argument, for example, <code>dt=0.1</code> .
<b>See also:</b>	<i>ZerosPolesGain</i> , <i>StateSpace</i> , <i>lti</i> , <i>dlti</i> , <i>tf2ss</i> , <i>tf2zpk</i> , <i>tf2sos</i>
<b>Notes</b>	Changing the value of properties that are not part of the <i>TransferFunction</i> system representation (such as the <i>A</i> , <i>B</i> , <i>C</i> , <i>D</i> state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call <code>sys = sys.to_ss()</code> before accessing/changing the <i>A</i> , <i>B</i> , <i>C</i> , <i>D</i> system matrices.  If (numerator, denominator) is passed in for <i>*system</i> , coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ or $z^2 + 3z + 5$ would be represented as <code>[1, 3, 5]</code> )

**Examples**

Construct the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```
>>> from scipy import signal
```

```
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```

```
>>> signal.TransferFunction(num, den)
TransferFunctionContinuous(
array([ 1.,  3.,  3.]),
array([ 1.,  2.,  1.]),
dt: None
)
```

Construct the transfer function with a sampling time of 0.1 seconds:

$$H(z) = \frac{z^2 + 3z + 3}{z^2 + 2z + 1}$$

```
>>> signal.TransferFunction(num, den, dt=0.1)
TransferFunctionDiscrete(
array([ 1.,  3.,  3.]),
array([ 1.,  2.,  1.]),
dt: 0.1
)
```

**Attributes**

<i>den</i>	Denominator of the <i>TransferFunction</i> system.
<i>dt</i>	Return the sampling time of the system, <i>None</i> for <i>lti</i> systems.
<i>num</i>	Numerator of the <i>TransferFunction</i> system.
<i>poles</i>	Poles of the system.
<i>zeros</i>	Zeros of the system.

`TransferFunction.den`  
Denominator of the *TransferFunction* system.

`TransferFunction.dt`  
Return the sampling time of the system, *None* for *lti* systems.

`TransferFunction.num`  
Numerator of the *TransferFunction* system.

`TransferFunction.poles`  
Poles of the system.

`TransferFunction.zeros`  
Zeros of the system.

*Methods*

<code>to_ss()</code>	Convert system representation to <i>StateSpace</i> .
<code>to_tf()</code>	Return a copy of the current <i>TransferFunction</i> system.
<code>to_zpk()</code>	Convert system representation to <i>ZerosPolesGain</i> .

`TransferFunction.to_ss()`

Convert system representation to *StateSpace*.

**Returns** `sys` : instance of *StateSpace*  
State space model of the current system

`TransferFunction.to_tf()`

Return a copy of the current *TransferFunction* system.

**Returns** `sys` : instance of *TransferFunction*  
The current system (copy)

`TransferFunction.to_zpk()`

Convert system representation to *ZerosPolesGain*.

**Returns** `sys` : instance of *ZerosPolesGain*  
Zeros, poles, gain representation of the current system

**class** `scipy.signal.ZerosPolesGain(*system, **kwargs)`

Linear Time Invariant system class in zeros, poles, gain form.

Represents the system as the continuous- or discrete-time transfer function  $H(s) = k \prod_i (s - z[i]) / \prod_j (s - p[j])$ , where  $k$  is the *gain*,  $z$  are the *zeros* and  $p$  are the *poles*. *ZerosPolesGain* systems inherit additional functionality from the *lti*, respectively the *dlti* classes, depending on which system representation is used.

**Parameters** `*system` : arguments

The *ZerosPolesGain* class can be instantiated with 1 or 3 arguments.

The following gives the number of input arguments and their interpretation:

- 1: *lti* or *dlti* system: (*StateSpace*, *TransferFunction* or *ZerosPolesGain*)
- 3: *array\_like*: (zeros, poles, gain)

**dt**: float, optional

Sampling time [s] of the discrete-time systems. Defaults to *None* (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

*TransferFunction*, *StateSpace*, *lti*, *dlti*, *zpk2ss*, *zpk2tf*, *zpk2sos*

**Notes**

Changing the value of properties that are not part of the *ZerosPolesGain* system representation (such as the *A*, *B*, *C*, *D* state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_ss()` before accessing/changing the *A*, *B*, *C*, *D* system matrices.

**Examples**

```
>>> from scipy import signal
```

Transfer function:  $H(s) = 5(s - 1)(s - 2) / (s - 3)(s - 4)$

```
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
array([1, 2]),
array([3, 4]),
5,
dt: None
)
```

Transfer function:  $H(z) = 5(z - 1)(z - 2) / (z - 3)(z - 4)$

```
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
array([1, 2]),
array([3, 4]),
5,
dt: 0.1
)
```

### Attributes

<code>dt</code>	Return the sampling time of the system, <i>None</i> for <i>lti</i> systems.
<code>gain</code>	Gain of the <i>ZerosPolesGain</i> system.
<code>poles</code>	Poles of the <i>ZerosPolesGain</i> system.
<code>zeros</code>	Zeros of the <i>ZerosPolesGain</i> system.

#### `ZerosPolesGain.dt`

Return the sampling time of the system, *None* for *lti* systems.

#### `ZerosPolesGain.gain`

Gain of the *ZerosPolesGain* system.

#### `ZerosPolesGain.poles`

Poles of the *ZerosPolesGain* system.

#### `ZerosPolesGain.zeros`

Zeros of the *ZerosPolesGain* system.

### Methods

<code>to_ss()</code>	Convert system representation to <i>StateSpace</i> .
<code>to_tf()</code>	Convert system representation to <i>TransferFunction</i> .
<code>to_zpk()</code>	Return a copy of the current 'ZerosPolesGain' system.

#### `ZerosPolesGain.to_ss()`

Convert system representation to *StateSpace*.

**Returns** `sys`: instance of *StateSpace*  
State space model of the current system

#### `ZerosPolesGain.to_tf()`

Convert system representation to *TransferFunction*.

**Returns** `sys`: instance of *TransferFunction*  
Transfer function of the current system

`ZerosPolesGain.to_zpk()`

Return a copy of the current ‘ZerosPolesGain’ system.

**Returns** `sys` : instance of `ZerosPolesGain`  
The current system (copy)

`scipy.signal.lsim(system, U, T, X0=None, interp=True)`

Simulate output of a continuous-time linear system.

**Parameters** `system` : an instance of the LTI class or a tuple describing the system.  
The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `lti`)
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

`U` : array\_like

An input array describing the input at each time  $T$  (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input. If  $U = 0$  or `None`, a zero input is used.

`T` : array\_like

The time steps at which the input is defined and at which the output is desired. Must be nonnegative, increasing, and equally spaced.

`X0` : array\_like, optional

The initial conditions on the state vector (zero by default).

`interp` : bool, optional

Whether to use linear (`True`, the default) or zero-order-hold (`False`) interpolation for the input array.

**Returns** `T` : 1D ndarray

Time values for the output.

`yout` : 1D ndarray

System response.

`xout` : ndarray

Time evolution of the state vector.

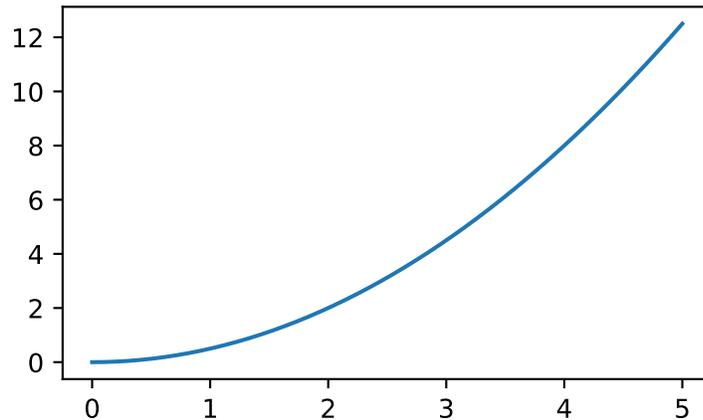

### Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

### Examples

Simulate a double integrator  $y'' = u$ , with a constant input  $u = 1$

```
>>> from scipy import signal
>>> system = signal.lti([[0., 1.], [0., 0.]], [[0.], [1.]], [[1., 0.]], 0.)
>>> t = np.linspace(0, 5)
>>> u = np.ones_like(t)
>>> tout, y, x = signal.lsim(system, u, t)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

`scipy.signal.lsim2(system, U=None, T=None, X0=None, **kwargs)`

Simulate output of a continuous-time linear system, by using the ODE solver `scipy.integrate.odeint`.

**Parameters** **system** : an instance of the `lti` class or a tuple describing the system.  
The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `lti`)
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

**U** : array\_like (1D or 2D), optional

An input array describing the input at each time `T`. Linear interpolation is used between given times. If there are multiple inputs, then each column of the rank-2 array represents an input. If `U` is not given, the input is assumed to be zero.

**T** : array\_like (1D or 2D), optional

The time steps at which the input is defined and at which the output is desired. The default is 101 evenly spaced points on the interval `[0,10.0]`.

**X0** : array\_like (1D), optional

The initial condition of the state vector. If `X0` is not given, the initial conditions are assumed to be 0.

**kwargs** : dict

Additional keyword arguments are passed on to the function `odeint`. See the notes below for more details.

**Returns** **T** : 1D ndarray

The time values for the output.

**yout** : ndarray

The response of the system.

**xout** : ndarray

The time-evolution of the state-vector.

### Notes

This function uses `scipy.integrate.odeint` to solve the system's differential equations. Additional keyword arguments given to `lsim2` are passed on to `odeint`. See the documentation for `scipy.integrate.odeint` for the full list of arguments.

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

`scipy.signal.impulse` (*system*, *X0=None*, *T=None*, *N=None*)

Impulse response of continuous-time system.

**Parameters**

- system** : an instance of the LTI class or a tuple of array\_like describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of *lti*)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- X0** : array\_like, optional  
Initial state-vector. Defaults to zero.
- T** : array\_like, optional  
Time points. Computed if not given.
- N** : int, optional  
The number of time points to compute (if *T* is not given).

**Returns**

- T** : ndarray  
A 1-D array of time points.
- yout** : ndarray  
A 1-D array containing the impulse response of the system (except for singularities at zero).

**Notes**

If (num, den) is passed in for *system*, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

`scipy.signal.impulse2` (*system*, *X0=None*, *T=None*, *N=None*, **\*\*kwargs**)

Impulse response of a single-input, continuous-time linear system.

**Parameters**

- system** : an instance of the LTI class or a tuple of array\_like describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of *lti*)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- X0** : 1-D array\_like, optional  
The initial condition of the state vector. Default: 0 (the zero vector).
- T** : 1-D array\_like, optional  
The time steps at which the input is defined and at which the output is desired. If *T* is not given, the function will generate a set of time samples automatically.
- N** : int, optional  
Number of time points to compute. Default: 100.
- kwargs** : various types  
Additional keyword arguments are passed on to the function `scipy.signal.lsim2`, which in turn passes them on to `scipy.integrate.odeint`; see the latter's documentation for information about these arguments.

**Returns**

- T** : ndarray  
The time values for the output.
- yout** : ndarray  
The output response of the system.

**See also:**

`impulse`, `lsim2`, `integrate.odeint`

**Notes**

The solution is generated by calling `scipy.signal.lsim2`, which uses the differential equation solver `scipy.integrate.odeint`.

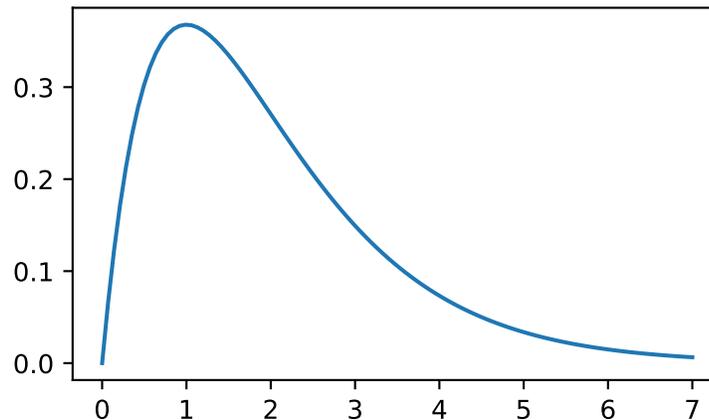

If `(num, den)` is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

New in version 0.8.0.

**Examples**

Second order system with a repeated root:  $x''(t) + 2x'(t) + x(t) = u(t)$

```
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse2(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

`scipy.signal.step` (`system`, `X0=None`, `T=None`, `N=None`)

Step response of continuous-time system.

**Parameters** `system` : an instance of the LTI class or a tuple of array\_like describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of `lti`)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

`X0` : array\_like, optional  
Initial state-vector (default is zero).

`T` : array\_like, optional  
Time points (computed if not given).

`N` : int, optional  
Number of time points to compute if `T` is not given.

**Returns** `T` : 1D ndarray  
Output time points.

`yout` : 1D ndarray  
Step response of system.

**See also:**

`scipy.signal.step2`

**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

`scipy.signal.step2` (*system*, *X0=None*, *T=None*, *N=None*, *\*\*kwargs*)  
 Step response of continuous-time system.

This function is functionally the same as `scipy.signal.step`, but it uses the function `scipy.signal.lsim2` to compute the step response.

**Parameters**

- system** : an instance of the LTI class or a tuple of array\_like describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of *lti*)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- X0** : array\_like, optional  
 Initial state-vector (default is zero).
- T** : array\_like, optional  
 Time points (computed if not given).
- N** : int, optional  
 Number of time points to compute if *T* is not given.
- kwargs** : various types  
 Additional keyword arguments are passed on the function `scipy.signal.lsim2`, which in turn passes them on to `scipy.integrate.odeint`. See the documentation for `scipy.integrate.odeint` for information about these arguments.

**Returns**

- T** : 1D ndarray  
 Output time points.
- yout** : 1D ndarray  
 Step response of system.

**See also:**

`scipy.signal.step`

**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

New in version 0.8.0.

`scipy.signal.freqresp` (*system*, *w=None*, *n=10000*)  
 Calculate the frequency response of a continuous-time system.

**Parameters**

- system** : an instance of the *lti* class or a tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of *lti*)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- w** : array\_like, optional  
 Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given, a reasonable set will be calculated.
- n** : int, optional

**Returns**

- w** : 1D ndarray  
Number of frequency points to compute if  $w$  is not given. The  $n$  frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.
- H** : 1D ndarray  
Frequency array [rad/s]  
Array of complex magnitude values

**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

**Examples**

Generating the Nyquist plot of a transfer function

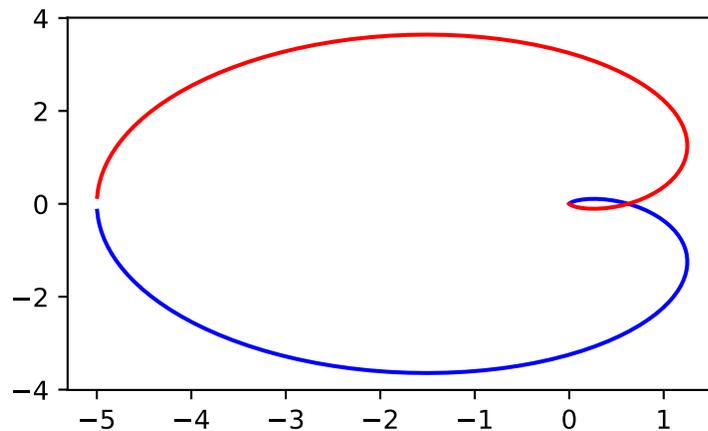

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Transfer function:  $H(s) = 5 / (s-1)^3$

```
>>> s1 = signal.ZerosPolesGain([], [1, 1, 1], [5])
```

```
>>> w, H = signal.freqresp(s1)
```

```
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```

`scipy.signal.bode` (*system*, *w=None*, *n=100*)

Calculate Bode magnitude and phase data of a continuous-time system.

**Parameters** **system** : an instance of the LTI class or a tuple describing the system.

The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of *Lti*)

- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

**w** : array\_like, optional  
 Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

**n** : int, optional  
 Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**Returns**

**w** : 1D ndarray  
 Frequency array [rad/s]  
**mag** : 1D ndarray  
 Magnitude array [dB]  
**phase** : 1D ndarray  
 Phase array [deg]

**Notes**

If (num, den) is passed in for *system*, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

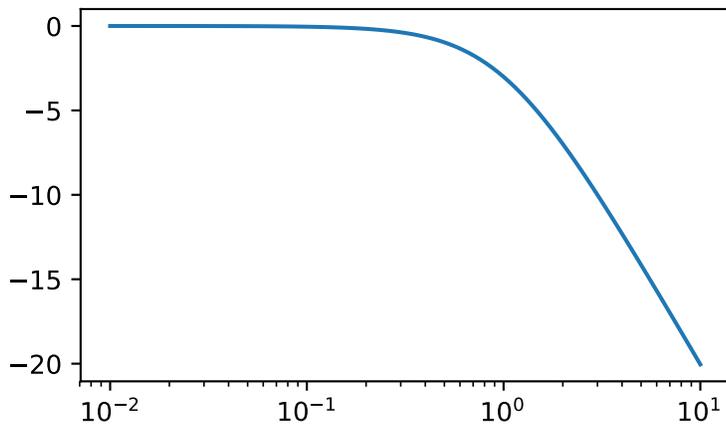

New in version 0.11.0.

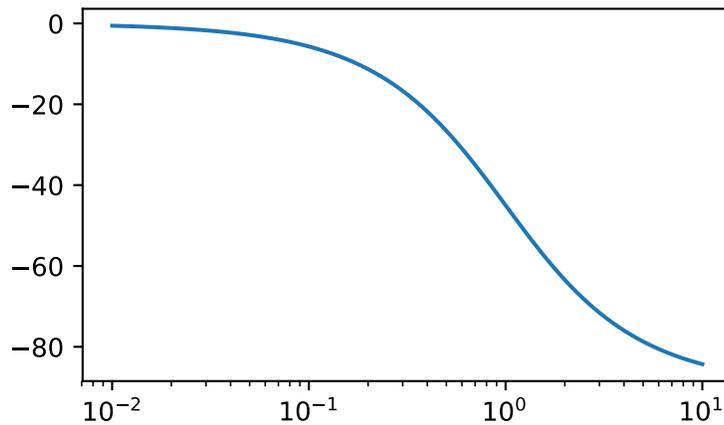

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = signal.bode(sys)
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag) # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase) # Bode phase plot
>>> plt.show()
```

### 5.20.7 Discrete-Time Linear Systems

<code>dlti(*system, **kwargs)</code>	Discrete-time linear time invariant system base class.
<code>StateSpace(*system, **kwargs)</code>	Linear Time Invariant system in state-space form.
<code>TransferFunction(*system, **kwargs)</code>	Linear Time Invariant system class in transfer function form.
<code>ZerosPolesGain(*system, **kwargs)</code>	Linear Time Invariant system class in zeros, poles, gain form.
<code>dlsim(system, u[, t, x0])</code>	Simulate output of a discrete-time linear system.
<code>dimpulse(system[, x0, t, n])</code>	Impulse response of discrete-time system.
<code>dstep(system[, x0, t, n])</code>	Step response of discrete-time system.
<code>dfreqresp(system[, w, n, whole])</code>	Calculate the frequency response of a discrete-time system.
<code>dbode(system[, w, n])</code>	Calculate Bode magnitude and phase data of a discrete-time system.

**class** `scipy.signal.dlti` (\*system, \*\*kwargs)  
Discrete-time linear time invariant system base class.

**Parameters** \*system: arguments

The `dlti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding discrete-time subclass that is created:

- 2: `TransferFunction`: (numerator, denominator)
- 3: `ZerosPolesGain`: (zeros, poles, gain)
- 4: `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

**dt**: float, optional

Sampling time [s] of the discrete-time systems. Defaults to `True` (unspecified sampling time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`ZerosPolesGain`, `StateSpace`, `TransferFunction`, `lti`

**Notes**

*dlti* instances do not exist directly. Instead, *dlti* creates an instance of one of its subclasses: *StateSpace*, *TransferFunction* or *ZerosPolesGain*.

Changing the value of properties that are not directly part of the current system representation (such as the *zeros* of a *StateSpace* system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

If (numerator, denominator) is passed in for *\*system*, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.,  $z^2 + 3z + 5$  would be represented as `[1, 3, 5]`).

New in version 0.18.0.

**Examples**

```
>>> from scipy import signal
```

```
>>> signal.dlti(1, 2, 3, 4)
StateSpaceDiscrete(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: True
)
```

```
>>> signal.dlti(1, 2, 3, 4, dt=0.1)
StateSpaceDiscrete(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: 0.1
)
```

```
>>> signal.dlti([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
array([1, 2]),
array([3, 4]),
5,
dt: 0.1
)
```

```
>>> signal.dlti([3, 4], [1, 2], dt=0.1)
TransferFunctionDiscrete(
array([ 3.,  4.]),
array([ 1.,  2.]),
dt: 0.1
)
```

**Attributes**

*dt*

Return the sampling time of the system.

Continued on next page

Table 5.154 – continued from previous page

<i>poles</i>	Poles of the system.
<i>zeros</i>	Zeros of the system.

`dlti.dt`  
Return the sampling time of the system.

`dlti.poles`  
Poles of the system.

`dlti.zeros`  
Zeros of the system.

### Methods

<code>bode([w, n])</code>	Calculate Bode magnitude and phase data of a discrete-time system.
<code>freqresp([w, n, whole])</code>	Calculate the frequency response of a discrete-time system.
<code>impulse([x0, t, n])</code>	Return the impulse response of the discrete-time <i>dlti</i> system.
<code>output(u, t[, x0])</code>	Return the response of the discrete-time system to input <i>u</i> .
<code>step([x0, t, n])</code>	Return the step response of the discrete-time <i>dlti</i> system.

`dlti.bode (w=None, n=100)`  
Calculate Bode magnitude and phase data of a discrete-time system.

Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See *dbode* for details.

### Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

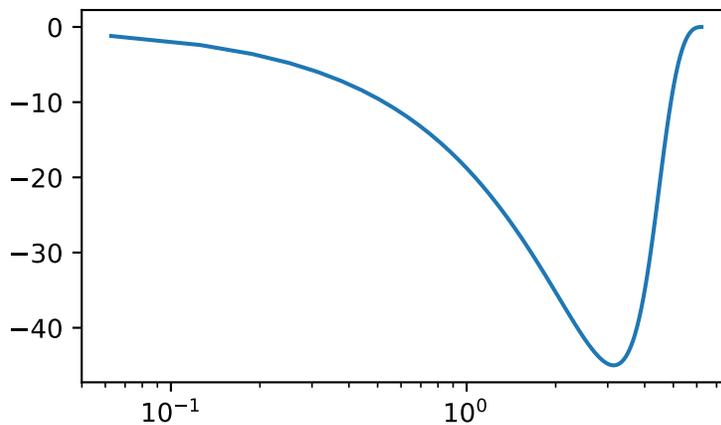

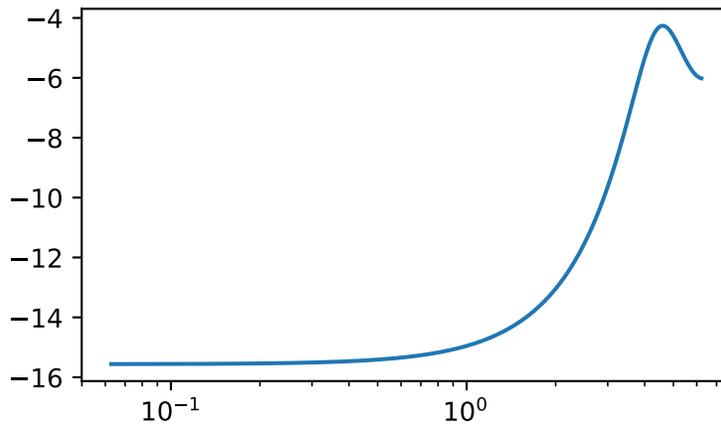

Transfer function:  $H(z) = 1 / (z^2 + 2z + 3)$  with sampling time 0.5s

```
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.5)
```

Equivalent: `signal.dbode(sys)`

```
>>> w, mag, phase = sys.bode()
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag)      # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)   # Bode phase plot
>>> plt.show()
```

`dlti.freqresp` (*w=None, n=10000, whole=False*)

Calculate the frequency response of a discrete-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See `dfreqresp` for details.

`dlti.impulse` (*x0=None, t=None, n=None*)

Return the impulse response of the discrete-time `dlti` system. See `dimpulse` for details.

`dlti.output` (*u, t, x0=None*)

Return the response of the discrete-time system to input *u*. See `dlsim` for details.

`dlti.step` (*x0=None, t=None, n=None*)

Return the step response of the discrete-time `dlti` system. See `dstep` for details.

`scipy.signal.dlsim` (*system, u, t=None, x0=None*)

Simulate output of a discrete-time linear system.

**Parameters** `system` : tuple of array\_like or instance of `dlti`

A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of *dlti*)
- 3: (num, den, dt)
- 4: (zeros, poles, gain, dt)
- 5: (A, B, C, D, dt)

**u** : array\_like

An input array describing the input at each time  $t$  (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input.

**t** : array\_like, optional

The time steps at which the input is defined. If  $t$  is given, it must be the same length as  $u$ , and the final value in  $t$  determines the number of steps returned in the output.

**x0** : array\_like, optional

The initial conditions on the state vector (zero by default).

**Returns**

**tout** : ndarray

Time values for the output, as a 1-D array.

**yout** : ndarray

System response, as a 1-D array.

**xout** : ndarray, optional

Time-evolution of the state-vector. Only generated if the input is a *StateSpace* system.

**See also:**

*lsim*, *dstep*, *dimpulse*, *cont2discrete*

**Examples**

A simple integrator transfer function with a discrete time step of 1.0 could be implemented as:

```
>>> from scipy import signal
>>> tf = ([1.0,], [1.0, -1.0], 1.0)
>>> t_in = [0.0, 1.0, 2.0, 3.0]
>>> u = np.asarray([0.0, 0.0, 1.0, 1.0])
>>> t_out, y = signal.dlsim(tf, u, t=t_in)
>>> y.T
array([[ 0.,  0.,  0.,  1.]])
```

`scipy.signal.dimpulse` (*system*, *x0=None*, *t=None*, *n=None*)

Impulse response of discrete-time system.

**Parameters** **system** : tuple of array\_like or instance of *dlti*

A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of *dlti*)
- 3: (num, den, dt)
- 4: (zeros, poles, gain, dt)
- 5: (A, B, C, D, dt)

**x0** : array\_like, optional

Initial state-vector. Defaults to zero.

**t** : array\_like, optional

Time points. Computed if not given.

**n** : int, optional

The number of time points to compute (if  $t$  is not given).

**Returns**

**tout** : ndarray

Time values for the output, as a 1-D array.

**yout** : ndarray

Impulse response of system. Each element of the tuple represents the output of the system based on an impulse in each input.

**See also:**

*impulse, dstep, dlsim, cont2discrete*

`scipy.signal.dstep` (*system, x0=None, t=None, n=None*)

Step response of discrete-time system.

**Parameters** **system** : tuple of array\_like

A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of *dlti*)
- 2: (num, den, dt)
- 3: (zeros, poles, gain, dt)
- 4: (A, B, C, D, dt)

**x0** : array\_like, optional

Initial state-vector. Defaults to zero.

**t** : array\_like, optional

Time points. Computed if not given.

**n** : int, optional

The number of time points to compute (if *t* is not given).

**Returns**

**tout** : ndarray

Output time points, as a 1-D array.

**yout** : ndarray

Step response of system. Each element of the tuple represents the output of the system based on a step response to each input.

**See also:**

*step, dimpulse, dlsim, cont2discrete*

`scipy.signal.dfreqresp` (*system, w=None, n=10000, whole=False*)

Calculate the frequency response of a discrete-time system.

**Parameters** **system** : an instance of the *dlti* class or a tuple describing the system.

The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of *dlti*)
- 2 (numerator, denominator, dt)
- 3 (zeros, poles, gain, dt)
- 4 (A, B, C, D, dt)

**w** : array\_like, optional

Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

**n** : int, optional

Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**whole** : bool, optional

Normally, if 'w' is not given, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to 2\*pi radians/sample.

**Returns**

**w** : 1D ndarray

Frequency array [radians/sample]

**H** : 1D ndarray

Array of complex magnitude values

**Notes**

If (num, den) is passed in for *system*, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $z^2 + 3z + 5$  would be represented as `[1, 3, 5]`).

New in version 0.18.0.

### Examples

Generating the Nyquist plot of a transfer function

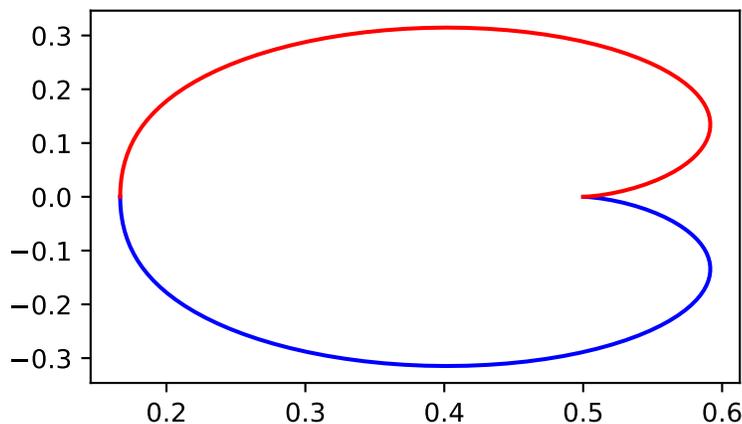

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Transfer function:  $H(z) = 1 / (z^2 + 2z + 3)$

```
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```

```
>>> w, H = signal.dfreqresp(sys)
```

```
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```

`scipy.signal.dbode` (*system*, *w=None*, *n=100*)

Calculate Bode magnitude and phase data of a discrete-time system.

**Parameters** **system** : an instance of the LTI class or a tuple describing the system.

The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of *dlti*)
- 2 (num, den, dt)
- 3 (zeros, poles, gain, dt)
- 4 (A, B, C, D, dt)

**w** : array\_like, optional

Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

**n** : int, optional

Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**Returns** **w** : 1D ndarray

Frequency array [rad/time\_unit]  
**mag** : 1D ndarray  
 Magnitude array [dB]  
**phase** : 1D ndarray  
 Phase array [deg]

### Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $z^2 + 3z + 5$  would be represented as `[1, 3, 5]`).

New in version 0.18.0.

### Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

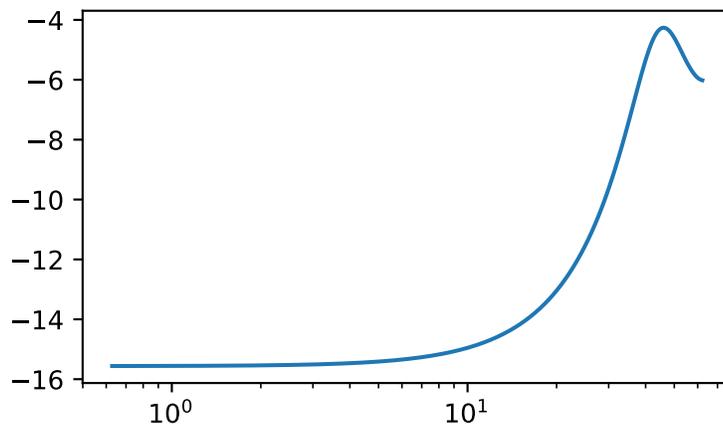

Transfer function:  $H(z) = 1 / (z^2 + 2z + 3)$

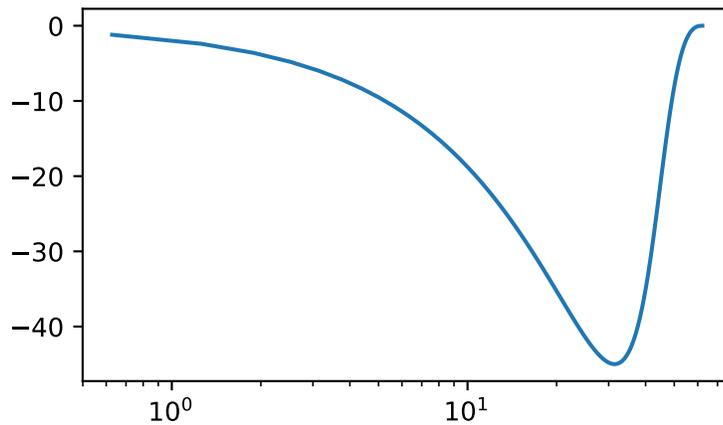

```
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```

Equivalent: `sys.bode()`

```
>>> w, mag, phase = signal.dbode(sys)
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag) # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase) # Bode phase plot
>>> plt.show()
```

## 5.20.8 LTI Representations

<code>tf2zpk(b, a)</code>	Return zero, pole, gain (z, p, k) representation from a numerator, denominator representation of a linear filter.
<code>tf2sos(b, a[, pairing])</code>	Return second-order sections from transfer function representation
<code>tf2ss(num, den)</code>	Transfer function to state-space representation.
<code>zpk2tf(z, p, k)</code>	Return polynomial transfer function representation from zeros and poles
<code>zpk2sos(z, p, k[, pairing])</code>	Return second-order sections from zeros, poles, and gain of a system
<code>zpk2ss(z, p, k)</code>	Zero-pole-gain representation to state-space representation
<code>ss2tf(A, B, C, D[, input])</code>	State-space to transfer function.
<code>ss2zpk(A, B, C, D[, input])</code>	State-space representation to zero-pole-gain representation.
<code>sos2zpk(sos)</code>	Return zeros, poles, and gain of a series of second-order sections
<code>sos2tf(sos)</code>	Return a single transfer function from a series of second-order sections
<code>cont2discrete(system, dt[, method, alpha])</code>	Transform a continuous to a discrete state-space system.
<code>place_poles(A, B, poles[, method, rtol, maxiter])</code>	Compute K such that eigenvalues (A - dot(B, K))=poles.

`scipy.signal.tf2zpk(b, a)`

Return zero, pole, gain (z, p, k) representation from a numerator, denominator representation of a linear filter.

**Parameters**

- b** : array\_like  
Numerator polynomial coefficients.
- a** : array\_like  
Denominator polynomial coefficients.

**Returns**

- z** : ndarray  
Zeros of the transfer function.
- p** : ndarray  
Poles of the transfer function.

**k** : float  
System gain.

**Notes**

If some values of  $b$  are too close to 0, they are removed. In that case, a `BadCoefficients` warning is emitted.

The  $b$  and  $a$  arrays are interpreted as coefficients for positive, descending powers of the transfer function variable. So the inputs  $b = [b_0, b_1, \dots, b_M]$  and  $a = [a_0, a_1, \dots, a_N]$  can represent an analog filter of the form:

$$H(s) = \frac{b_0 s^M + b_1 s^{(M-1)} + \dots + b_M}{a_0 s^N + a_1 s^{(N-1)} + \dots + a_N}$$

or a discrete-time filter of the form:

$$H(z) = \frac{b_0 z^M + b_1 z^{(M-1)} + \dots + b_M}{a_0 z^N + a_1 z^{(N-1)} + \dots + a_N}$$

This “positive powers” form is found more commonly in controls engineering. If  $M$  and  $N$  are equal (which is true for all filters generated by the bilinear transform), then this happens to be equivalent to the “negative powers” discrete-time form preferred in DSP:

$$H(z) = \frac{b_0 + b_1 z^{-1} + \dots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \dots + a_N z^{-N}}$$

Although this is true for common filters, remember that this is not true in the general case. If  $M$  and  $N$  are not equal, the discrete-time transfer function coefficients must first be converted to the “positive powers” form before finding the poles and zeros.

`scipy.signal.tf2sos(b, a, pairing='nearest')`

Return second-order sections from transfer function representation

**Parameters**

- b** : array\_like  
Numerator polynomial coefficients.
- a** : array\_like  
Denominator polynomial coefficients.
- pairing** : {'nearest', 'keep\_odd'}, optional  
The method to use to combine pairs of poles and zeros into sections. See `zpk2sos`.

**Returns**

- sos** : ndarray  
Array of second-order filter coefficients, with shape `(n_sections, 6)`. See `sosfilt` for the SOS filter format specification.

**See also:**

`zpk2sos`, `sosfilt`

**Notes**

It is generally discouraged to convert from TF to SOS format, since doing so usually will not improve numerical precision errors. Instead, consider designing filters in ZPK format and converting directly to SOS. TF is converted to SOS by first converting to ZPK format, then converting ZPK to SOS.

New in version 0.16.0.

`scipy.signal.tf2ss(num, den)`

Transfer function to state-space representation.

**Parameters**

- num, den** : array\_like  
Sequences representing the coefficients of the numerator and denominator polynomials, in order of descending degree. The denominator needs to be at least as long as the numerator.

**Returns**

- A, B, C, D** : ndarray  
State space representation of the system, in controller canonical form.

**Examples**

Convert the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```

to the state-space representation:

$$\dot{\mathbf{x}}(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \mathbf{u}(t)$$

$$\mathbf{y}(t) = [1 \ 2] \mathbf{x}(t) + [1] \mathbf{u}(t)$$

```
>>> from scipy.signal import tf2ss
>>> A, B, C, D = tf2ss(num, den)
>>> A
array([[ -2.,  -1.],
       [  1.,   0.]])
>>> B
array([[ 1.],
       [ 0.]])
>>> C
array([[ 1.,  2.]])
>>> D
array([[ 1.]])
```

`scipy.signal.zpk2tf` (*z*, *p*, *k*)

Return polynomial transfer function representation from zeros and poles

**Parameters**

- z** : array\_like  
Zeros of the transfer function.
- p** : array\_like  
Poles of the transfer function.
- k** : float  
System gain.

**Returns**

- b** : ndarray  
Numerator polynomial coefficients.
- a** : ndarray  
Denominator polynomial coefficients.

`scipy.signal.zpk2sos` (*z*, *p*, *k*, *pairing*=*'nearest'*)

Return second-order sections from zeros, poles, and gain of a system

**Parameters**

- z** : array\_like  
Zeros of the transfer function.
- p** : array\_like  
Poles of the transfer function.
- k** : float  
System gain.
- pairing** : {'nearest', 'keep\_odd'}, optional  
The method to use to combine pairs of poles and zeros into sections. See Notes below.

**Returns**

- sos** : ndarray

Array of second-order filter coefficients, with shape `(n_sections, 6)`. See `sosfilt` for the SOS filter format specification.

**See also:**

`sosfilt`

**Notes**

The algorithm used to convert ZPK to SOS format is designed to minimize errors due to numerical precision issues. The pairing algorithm attempts to minimize the peak gain of each biquadratic section. This is done by pairing poles with the nearest zeros, starting with the poles closest to the unit circle.

**Algorithms**

The current algorithms are designed specifically for use with digital filters. (The output coefficients are not correct for analog filters.)

The steps in the `pairing='nearest'` and `pairing='keep_odd'` algorithms are mostly shared. The `nearest` algorithm attempts to minimize the peak gain, while `'keep_odd'` minimizes peak gain under the constraint that odd-order systems should retain one section as first order. The algorithm steps and are as follows:

As a pre-processing step, add poles or zeros to the origin as necessary to obtain the same number of poles and zeros for pairing. If `pairing == 'nearest'` and there are an odd number of poles, add an additional pole and a zero at the origin.

The following steps are then iterated over until no more poles or zeros remain:

1. Take the (next remaining) pole (complex or real) closest to the unit circle to begin a new filter section.
2. If the pole is real and there are no other remaining real poles<sup>1</sup>, add the closest real zero to the section and leave it as a first order section. Note that after this step we are guaranteed to be left with an even number of real poles, complex poles, real zeros, and complex zeros for subsequent pairing iterations.
3. Else:
  - (a) If the pole is complex and the zero is the only remaining real zero\*, then pair the pole with the *next* closest zero (guaranteed to be complex). This is necessary to ensure that there will be a real zero remaining to eventually create a first-order section (thus keeping the odd order).
  - (b) Else pair the pole with the closest remaining zero (complex or real).
  - (c) Proceed to complete the second-order section by adding another pole and zero to the current pole and zero in the section:
    - i. If the current pole and zero are both complex, add their conjugates.
    - ii. Else if the pole is complex and the zero is real, add the conjugate pole and the next closest real zero.
    - iii. Else if the pole is real and the zero is complex, add the conjugate zero and the real pole closest to those zeros.
    - iv. Else (we must have a real pole and real zero) add the next real pole closest to the unit circle, and then add the real zero closest to that pole.

New in version 0.16.0.

**Examples**

Design a 6th order low-pass elliptic digital filter for a system with a sampling rate of 8000 Hz that has a pass-band corner frequency of 1000 Hz. The ripple in the pass-band should not exceed 0.087 dB, and the attenuation in the stop-band should be at least 90 dB.

In the following call to `signal.ellip`, we could use `output='sos'`, but for this example, we'll use `output='zpk'`, and then convert to SOS format with `zpk2sos`:

```
>>> from scipy import signal
>>> z, p, k = signal.ellip(6, 0.087, 90, 1000/(0.5*8000), output='zpk')
```

<sup>1</sup> This conditional can only be met for specific odd-order inputs with the `pairing == 'keep_odd'` method.

Now convert to SOS format.

```
>>> sos = signal.zpk2sos(z, p, k)
```

The coefficients of the numerators of the sections:

```
>>> sos[:, :3]
array([[ 0.0014154 ,  0.00248707,  0.0014154 ],
       [ 1.          ,  0.72965193,  1.          ],
       [ 1.          ,  0.17594966,  1.          ]])
```

The symmetry in the coefficients occurs because all the zeros are on the unit circle.

The coefficients of the denominators of the sections:

```
>>> sos[:, 3:]
array([[ 1.          , -1.32543251,  0.46989499],
       [ 1.          , -1.26117915,  0.6262586 ],
       [ 1.          , -1.25707217,  0.86199667]])
```

The next example shows the effect of the *pairing* option. We have a system with three poles and three zeros, so the SOS array will have shape (2, 6). This means there is, in effect, an extra pole and an extra zero at the origin in the SOS representation.

```
>>> z1 = np.array([-1, -0.5-0.5j, -0.5+0.5j])
>>> p1 = np.array([0.75, 0.8+0.1j, 0.8-0.1j])
```

With `pairing='nearest'` (the default), we obtain

```
>>> signal.zpk2sos(z1, p1, 1)
array([[ 1. ,  1. ,  0.5 ,  1. , -0.75,  0. ],
       [ 1. ,  1. ,  0. ,  1. , -1.6 ,  0.65]])
```

The first section has the zeros  $\{-0.5-0.05j, -0.5+0.5j\}$  and the poles  $\{0, 0.75\}$ , and the second section has the zeros  $\{-1, 0\}$  and poles  $\{0.8+0.1j, 0.8-0.1j\}$ . Note that the extra pole and zero at the origin have been assigned to different sections.

With `pairing='keep_odd'`, we obtain:

```
>>> signal.zpk2sos(z1, p1, 1, pairing='keep_odd')
array([[ 1. ,  1. ,  0. ,  1. , -0.75,  0. ],
       [ 1. ,  1. ,  0.5 ,  1. , -1.6 ,  0.65]])
```

The extra pole and zero at the origin are in the same section. The first section is, in effect, a first-order section.

`scipy.signal.zpk2ss(z, p, k)`

Zero-pole-gain representation to state-space representation

**Parameters** **z, p**: sequence  
Zeros and poles.

**k**: float

**Returns** **A, B, C, D**: ndarray  
System gain.  
State space representation of the system, in controller canonical form.

`scipy.signal.ss2tf(A, B, C, D, input=0)`

State-space to transfer function.

A, B, C, D defines a linear state-space system with  $p$  inputs,  $q$  outputs, and  $n$  state variables.

**Parameters** **A**: array\_like

State (or system) matrix of shape  $(n, n)$

**B** : array\_like  
Input matrix of shape  $(n, p)$

**C** : array\_like  
Output matrix of shape  $(q, n)$

**D** : array\_like  
Feedthrough (or feedforward) matrix of shape  $(q, p)$

**input** : int, optional  
For multiple-input systems, the index of the input to use.

**Returns**

**num** : 2-D ndarray  
Numerator(s) of the resulting transfer function(s). *num* has one row for each of the system's outputs. Each row is a sequence representation of the numerator polynomial.

**den** : 1-D ndarray  
Denominator of the resulting transfer function(s). *den* is a sequence representation of the denominator polynomial.

### Examples

Convert the state-space representation:

$$\dot{\mathbf{x}}(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \mathbf{u}(t)$$

$$\mathbf{y}(t) = [1 \ 2] \mathbf{x}(t) + [1] \mathbf{u}(t)$$

```
>>> A = [[-2, -1], [1, 0]]
>>> B = [[1], [0]] # 2-dimensional column vector
>>> C = [[1, 2]] # 2-dimensional row vector
>>> D = 1
```

to the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```
>>> from scipy.signal import ss2tf
>>> ss2tf(A, B, C, D)
(array([[1, 3, 3]]), array([ 1., 2., 1.]))
```

`scipy.signal.ss2zpk(A, B, C, D, input=0)`

State-space representation to zero-pole-gain representation.

A, B, C, D defines a linear state-space system with  $p$  inputs,  $q$  outputs, and  $n$  state variables.

**Parameters**

**A** : array\_like  
State (or system) matrix of shape  $(n, n)$

**B** : array\_like  
Input matrix of shape  $(n, p)$

**C** : array\_like  
Output matrix of shape  $(q, n)$

**D** : array\_like  
Feedthrough (or feedforward) matrix of shape  $(q, p)$

**input** : int, optional  
For multiple-input systems, the index of the input to use.

**Returns**

**z, p** : sequence

**k** : float  
Zeros and poles.  
System gain.

`scipy.signal.sos2zpk` (*sos*)

Return zeros, poles, and gain of a series of second-order sections

**Parameters** **sos** : array\_like  
Array of second-order filter coefficients, must have shape  $(n\_sections, 6)$ . See `sosfilt` for the SOS filter format specification.

**Returns** **z** : ndarray  
Zeros of the transfer function.

**p** : ndarray  
Poles of the transfer function.

**k** : float  
System gain.

#### Notes

New in version 0.16.0.

`scipy.signal.sos2tf` (*sos*)

Return a single transfer function from a series of second-order sections

**Parameters** **sos** : array\_like  
Array of second-order filter coefficients, must have shape  $(n\_sections, 6)$ . See `sosfilt` for the SOS filter format specification.

**Returns** **b** : ndarray  
Numerator polynomial coefficients.

**a** : ndarray  
Denominator polynomial coefficients.

#### Notes

New in version 0.16.0.

`scipy.signal.cont2discrete` (*system, dt, method='zoh', alpha=None*)

Transform a continuous to a discrete state-space system.

**Parameters** **system** : a tuple describing the system or an instance of `lti`  
The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `lti`)
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

**dt** : float  
The discretization time step.

**method** : {"gbt", "bilinear", "euler", "backward\_diff", "zoh"}, optional  
Which method to use:

- gbt: generalized bilinear transformation
- bilinear: Tustin's approximation ("gbt" with `alpha=0.5`)
- euler: Euler (or forward differencing) method ("gbt" with `alpha=0`)
- backward\_diff: Backwards differencing ("gbt" with `alpha=1.0`)
- zoh: zero-order hold (default)

**alpha** : float within [0, 1], optional  
The generalized bilinear transformation weighting parameter, which should only be specified with `method="gbt"`, and is ignored otherwise

**Returns** **sysd** : tuple containing the discrete system  
Based on the input type, the output will be of the form

- (num, den, dt) for transfer function input.
- (zeros, poles, gain, dt) for zeros-poles-gain input

•(A, B, C, D, dt) for state-space system input

**Notes**

By default, the routine uses a Zero-Order Hold (zoh) method to perform the transformation. Alternatively, a generalized bilinear transformation may be used, which includes the common Tustin's bilinear approximation, an Euler's method technique, or a backwards differencing technique.

The Zero-Order Hold (zoh) method is based on [R246], the generalized bilinear approximation is based on [R247] and [R248].

**References**

[R246], [R247], [R248]

`scipy.signal.place_poles(A, B, poles, method='YT', rtol=0.001, maxiter=30)`

Compute K such that eigenvalues  $(A - B \cdot K) = \text{poles}$ .

K is the gain matrix such as the plant described by the linear system  $AX + BU$  will have its closed-loop poles, i.e the eigenvalues  $A - B \cdot K$ , as close as possible to those asked for in poles.

SISO, MISO and MIMO systems are supported.

**Parameters** **A, B** : ndarray

State-space representation of linear system  $AX + BU$ .

**poles** : array\_like

Desired real poles and/or complex conjugates poles. Complex poles are only supported with `method="YT"` (default).

**method**: {'YT', 'KNV0'}, optional

Which method to choose to find the gain matrix K. One of:

- 'YT': Yang Tits
- 'KNV0': Kautsky, Nichols, Van Dooren update method 0

See References and Notes for details on the algorithms.

**rtol**: float, optional

After each iteration the determinant of the eigenvectors of  $A - B \cdot K$  is compared to its previous value, when the relative error between these two values becomes lower than `rtol` the algorithm stops. Default is  $1e-3$ .

**maxiter**: int, optional

Maximum number of iterations to compute the gain matrix. Default is 30.

**Returns**

**full\_state\_feedback** : Bunch object

*full\_state\_feedback is composed of:*

**gain\_matrix** [1-D ndarray] The closed loop matrix K such as the eigenvalues of  $A - BK$  are as close as possible to the requested poles.

**computed\_poles**

[1-D ndarray] The poles corresponding to  $A - BK$  sorted as first the real poles in increasing order, then the complex conjugates in lexicographic order.

**requested\_poles**

[1-D ndarray] The poles the algorithm was asked to place sorted as above, they may differ from what was achieved.

**X**

[2-D ndarray] The transfer matrix such as  $X * \text{diag}(\text{poles}) = (A - B \cdot K) * X$  (see Notes)

<b><i>rtol</i></b>	[float] The relative tolerance achieved on $\det(X)$ (see Notes). <i>rtol</i> will be NaN if it is possible to solve the system $\text{diag}(\text{poles}) = (A - B*K)$ , or 0 when the optimization algorithms can't do anything i.e when $B.\text{shape}[1] == 1$ .
<b><i>nb_iter</i></b>	[int] The number of iterations performed before converging. <i>nb_iter</i> will be NaN if it is possible to solve the system $\text{diag}(\text{poles}) = (A - B*K)$ , or 0 when the optimization algorithms can't do anything i.e when $B.\text{shape}[1] == 1$ .

### Notes

The Tits and Yang (YT), [R295] paper is an update of the original Kautsky et al. (KNV) paper [R294]. KNV relies on rank-1 updates to find the transfer matrix  $X$  such that  $X * \text{diag}(\text{poles}) = (A - B*K)*X$ , whereas YT uses rank-2 updates. This yields on average more robust solutions (see [R295] pp 21-22), furthermore the YT algorithm supports complex poles whereas KNV does not in its original version. Only update method 0 proposed by KNV has been implemented here, hence the name 'KNV0'.

KNV extended to complex poles is used in Matlab's `place` function, YT is distributed under a non-free licence by Slicot under the name `robpole`. It is unclear and undocumented how KNV0 has been extended to complex poles (Tits and Yang claim on page 14 of their paper that their method can not be used to extend KNV to complex poles), therefore only YT supports them in this implementation.

As the solution to the problem of pole placement is not unique for MIMO systems, both methods start with a tentative transfer matrix which is altered in various way to increase its determinant. Both methods have been proven to converge to a stable solution, however depending on the way the initial transfer matrix is chosen they will converge to different solutions and therefore there is absolutely no guarantee that using 'KNV0' will yield results similar to Matlab's or any other implementation of these algorithms.

Using the default method 'YT' should be fine in most cases; 'KNV0' is only provided because it is needed by 'YT' in some specific cases. Furthermore 'YT' gives on average more robust results than 'KNV0' when  $\text{abs}(\det(X))$  is used as a robustness indicator.

[R295] is available as a technical report on the following URL: <http://drum.lib.umd.edu/handle/1903/5598>

### References

[R294], [R295]

### Examples

A simple example demonstrating real pole placement using both KNV and YT algorithms. This is example number 1 from section 4 of the reference KNV publication ([R294]):

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> A = np.array([[ 1.380,  -0.2077,  6.715,  -5.676  ],
...              [-0.5814, -4.290,   0,      0.6750  ],
...              [ 1.067,   4.273,  -6.654,  5.893  ],
...              [ 0.0480,  4.273,   1.343, -2.104  ]])
>>> B = np.array([[ 0,   5.679  ],
...              [ 1.136,  1.136  ],
...              [ 0,   0,   ]])
```

```
...          [-3.146,  0      ]])
>>> P = np.array([-0.2, -0.5, -5.0566, -8.6659])
```

Now compute  $K$  with KNV method 0, with the default YT method and with the YT method while forcing 100 iterations of the algorithm and print some results after each call.

```
>>> fsf1 = signal.place_poles(A, B, P, method='KNV0')
>>> fsf1.gain_matrix
array([[ 0.20071427, -0.96665799,  0.24066128, -0.10279785],
       [ 0.50587268,  0.57779091,  0.51795763, -0.41991442]])
```

```
>>> fsf2 = signal.place_poles(A, B, P) # uses YT method
>>> fsf2.computed_poles
array([-8.6659, -5.0566, -0.5      , -0.2     ])
```

```
>>> fsf3 = signal.place_poles(A, B, P, rtol=-1, maxiter=100)
>>> fsf3.X
array([[ 0.52072442+0.j, -0.08409372+0.j, -0.56847937+0.j,  0.74823657+0.j],
       [-0.04977751+0.j, -0.80872954+0.j,  0.13566234+0.j, -0.29322906+0.j],
       [-0.82266932+0.j, -0.19168026+0.j, -0.56348322+0.j, -0.43815060+0.j],
       [ 0.22267347+0.j,  0.54967577+0.j, -0.58387806+0.j, -0.40271926+0.j]])
```

The absolute value of the determinant of  $X$  is a good indicator to check the robustness of the results, both 'KNV0' and 'YT' aim at maximizing it. Below a comparison of the robustness of the results above:

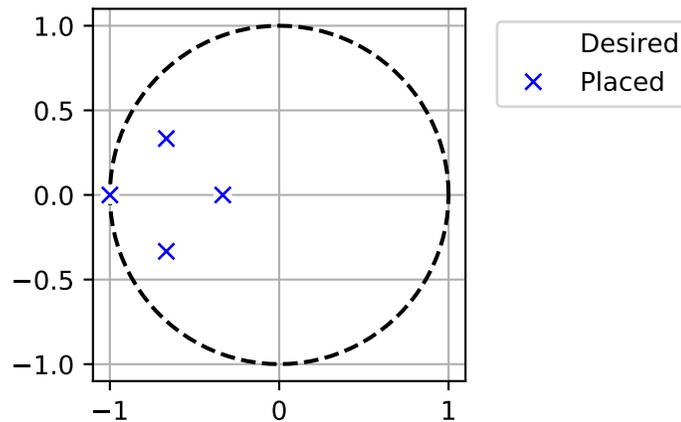

```
>>> abs(np.linalg.det(fsf1.X)) < abs(np.linalg.det(fsf2.X))
True
>>> abs(np.linalg.det(fsf2.X)) < abs(np.linalg.det(fsf3.X))
True
```

Now a simple example for complex poles:

```
>>> A = np.array([[ 0,  7/3.,  0,  0 ],
...             [ 0,  0,  0,  7/9. ],
...             [ 0,  0,  0,  0 ],
...             [ 0,  0,  0,  0 ]])
>>> B = np.array([[ 0,  0 ],
...             [ 0,  0 ],
...             [ 1,  0 ],
...             [ 0,  1 ]])
>>> P = np.array([-3, -1, -2-1j, -2+1j]) / 3.
>>> fsf = signal.place_poles(A, B, P, method='YT')
```

We can plot the desired and computed poles in the complex plane:

```
>>> t = np.linspace(0, 2*np.pi, 401)
>>> plt.plot(np.cos(t), np.sin(t), 'k--') # unit circle
>>> plt.plot(fsf.requested_poles.real, fsf.requested_poles.imag,
...         'wo', label='Desired')
>>> plt.plot(fsf.computed_poles.real, fsf.computed_poles.imag, 'bx',
...         label='Placed')
>>> plt.grid()
>>> plt.axis('image')
>>> plt.axis([-1.1, 1.1, -1.1, 1.1])
>>> plt.legend(bbox_to_anchor=(1.05, 1), loc=2, numpoints=1)
```

### 5.20.9 Waveforms

<code>chirp(t, f0, t1, f1[, method, phi, vertex_zero])</code>	Frequency-swept cosine generator.
<code>gausspulse(t[, fc, bw, bwr, tpr, retquad, ...])</code>	Return a Gaussian modulated sinusoid:
<code>max_len_seq(nbites[, state, length, taps])</code>	Maximum length sequence (MLS) generator.
<code>sawtooth(t[, width])</code>	Return a periodic sawtooth or triangle waveform.
<code>square(t[, duty])</code>	Return a periodic square-wave waveform.
<code>sweep_poly(t, poly[, phi])</code>	Frequency-swept cosine generator, with a time-dependent frequency.
<code>unit_impulse(shape[, idx, dtype])</code>	Unit impulse signal (discrete delta function) or unit basis vector.

`scipy.signal.chirp(t, f0, t1, f1, method='linear', phi=0, vertex_zero=True)`

Frequency-swept cosine generator.

In the following, ‘Hz’ should be interpreted as ‘cycles per unit’; there is no requirement here that the unit is one second. The important distinction is that the units of rotation are cycles, not radians. Likewise,  $t$  could be a measurement of space instead of time.

<b>Parameters</b>	<b>t</b> : array_like	Times at which to evaluate the waveform.
	<b>f0</b> : float	Frequency (e.g. Hz) at time $t=0$ .
	<b>t1</b> : float	Time at which $f1$ is specified.
	<b>f1</b> : float	Frequency (e.g. Hz) of the waveform at time $t1$ .
	<b>method</b> : {‘linear’, ‘quadratic’, ‘logarithmic’, ‘hyperbolic’}, optional	Kind of frequency sweep. If not given, <i>linear</i> is assumed. See Notes below for more details.
	<b>phi</b> : float, optional	Phase offset, in degrees. Default is 0.
	<b>vertex_zero</b> : bool, optional	

**Returns** `y` : ndarray

This parameter is only used when *method* is 'quadratic'. It determines whether the vertex of the parabola that is the graph of the frequency is at  $t=0$  or  $t=t1$ .

A numpy array containing the signal evaluated at  $t$  with the requested time-varying frequency. More precisely, the function returns  $\cos(\text{phase} + (\pi/180) * \text{phi})$  where *phase* is the integral (from 0 to  $t$ ) of  $2 * \pi * f(t)$ .  $f(t)$  is defined below.

**See also:**

`sweep_poly`

**Notes**

There are four options for the *method*. The following formulas give the instantaneous frequency (in Hz) of the signal generated by `chirp()`. For convenience, the shorter names shown below may also be used.

linear, lin, li:

$$f(t) = f0 + (f1 - f0) * t / t1$$

quadratic, quad, q:

The graph of the frequency  $f(t)$  is a parabola through  $(0, f0)$  and  $(t1, f1)$ . By default, the vertex of the parabola is at  $(0, f0)$ . If *vertex\_zero* is False, then the vertex is at  $(t1, f1)$ . The formula is:

if *vertex\_zero* is True:

$$f(t) = f0 + (f1 - f0) * t**2 / t1**2$$

else:

$$f(t) = f1 - (f1 - f0) * (t1 - t)**2 / t1**2$$

To use a more general quadratic function, or an arbitrary polynomial, use the function `scipy.signal.waveforms.sweep_poly`.

logarithmic, log, lo:

$$f(t) = f0 * (f1/f0)**(t/t1)$$

$f0$  and  $f1$  must be nonzero and have the same sign.

This signal is also known as a geometric or exponential chirp.

hyperbolic, hyp:

$$f(t) = f0 * f1 * t1 / ((f0 - f1) * t + f1 * t1)$$

$f0$  and  $f1$  must be nonzero.

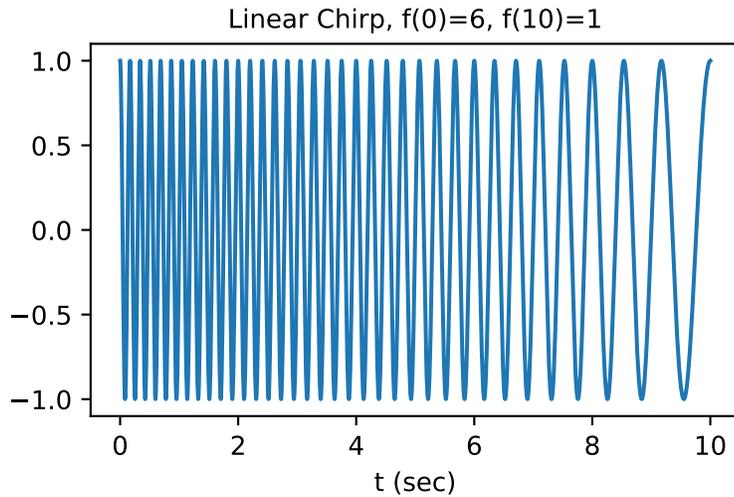

**Examples**

The following will be used in the examples:

```
>>> from scipy.signal import chirp, spectrogram
>>> import matplotlib.pyplot as plt
```

For the first example, we'll plot the waveform for a linear chirp from 6 Hz to 1 Hz over 10 seconds:

```
>>> t = np.linspace(0, 10, 5001)
>>> w = chirp(t, f0=6, f1=1, t1=10, method='linear')
>>> plt.plot(t, w)
>>> plt.title("Linear Chirp, f(0)=6, f(10)=1")
>>> plt.xlabel('t (sec)')
>>> plt.show()
```

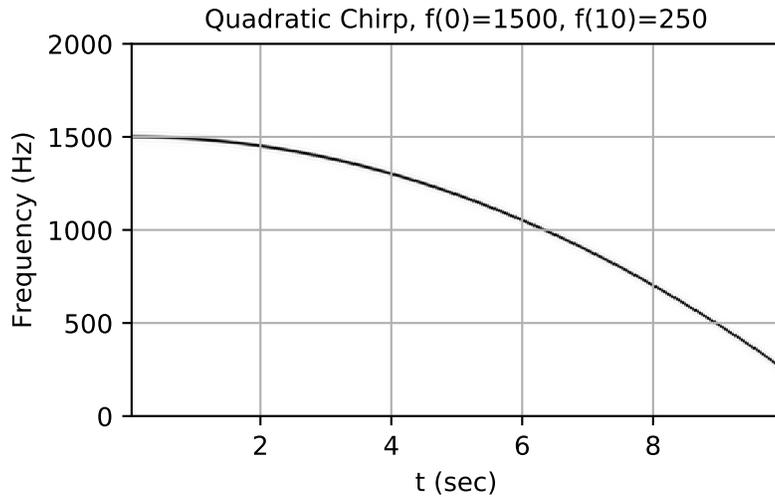

For the remaining examples, we'll use higher frequency ranges, and demonstrate the result using `scipy.signal.spectrogram`. We'll use a 10 second interval sampled at 8000 Hz.

```
>>> fs = 8000
>>> T = 10
>>> t = np.linspace(0, T, T*fs, endpoint=False)
```

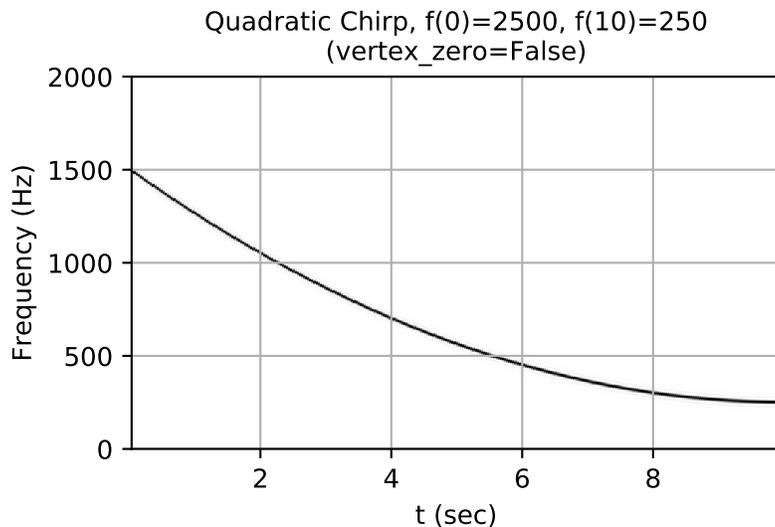

Quadratic chirp from 1500 Hz to 250 Hz over 10 seconds (vertex of the parabolic curve of the frequency is at  $t=0$ ):

```
>>> w = chirp(t, f0=1500, f1=250, t1=10, method='quadratic')
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512,
...                           nfft=2048)
>>> plt.pcolormesh(tt, ff[:513], Sxx[:513], cmap='gray_r')
>>> plt.title('Quadratic Chirp, f(0)=1500, f(10)=250')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()
```

Quadratic chirp from 1500 Hz to 250 Hz over 10 seconds (vertex of the parabolic curve of the frequency is at  $t=10$ ):

```
>>> w = chirp(t, f0=1500, f1=250, t1=10, method='quadratic',
...          vertex_zero=False)
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512,
...                            nfft=2048)
>>> plt.pcolormesh(tt, ff[:513], Sxx[:513], cmap='gray_r')
>>> plt.title('Quadratic Chirp, f(0)=2500, f(10)=250\n' +
...          '(vertex_zero=False)')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()
```

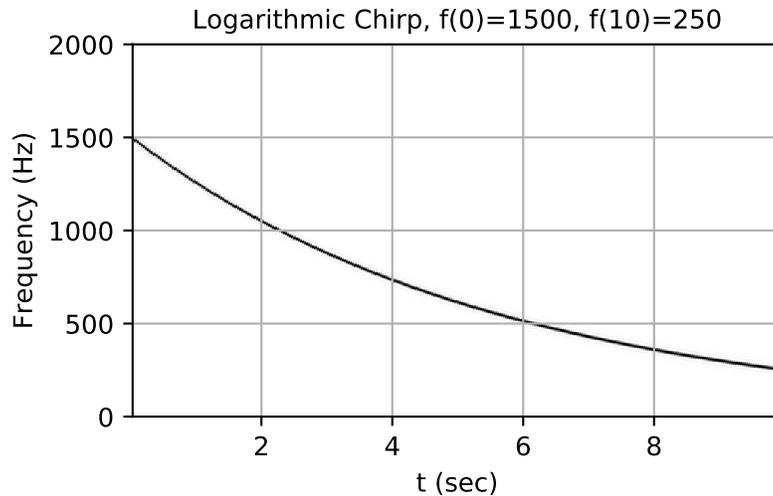

Logarithmic chirp from 1500 Hz to 250 Hz over 10 seconds:

```

>>> w = chirp(t, f0=1500, f1=250, t1=10, method='logarithmic')
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512,
...                             nfft=2048)
>>> plt.pcolormesh(tt, ff[:513], Sxx[:513], cmap='gray_r')
>>> plt.title('Logarithmic Chirp, f(0)=1500, f(10)=250')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()

```

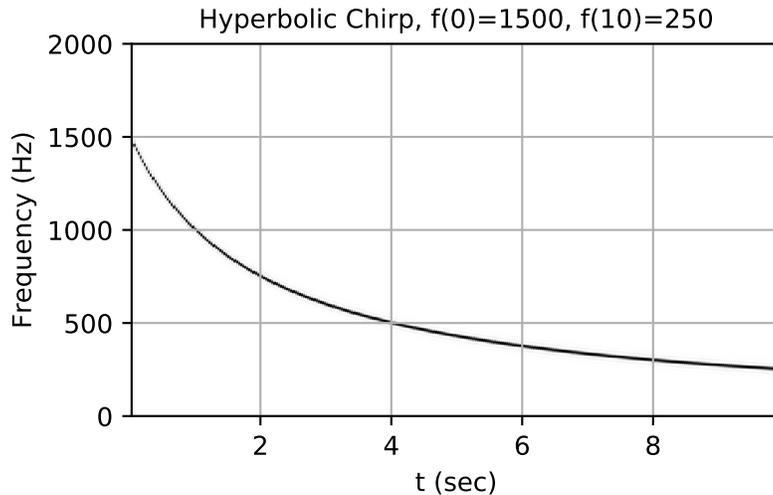

Hyperbolic chirp from 1500 Hz to 250 Hz over 10 seconds:

```

>>> w = chirp(t, f0=1500, f1=250, t1=10, method='hyperbolic')
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512,
...                             nfft=2048)
>>> plt.pcolormesh(tt, ff[:513], Sxx[:513], cmap='gray_r')
>>> plt.title('Hyperbolic Chirp, f(0)=1500, f(10)=250')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()

```

`scipy.signal.gausspulse` (*t*, *fc*=1000, *bw*=0.5, *bwr*=-6, *tpr*=-60, *retquad*=False, *retenv*=False)

Return a Gaussian modulated sinusoid:

$$\exp(-a t^2) \exp(1j \cdot 2 \cdot \pi \cdot f_c \cdot t).$$

If *retquad* is True, then return the real and imaginary parts (in-phase and quadrature). If *retenv* is True, then return the envelope (unmodulated signal). Otherwise, return the real part of the modulated sinusoid.

**Parameters**

- t** : ndarray or the string 'cutoff'  
Input array.
- fc** : int, optional  
Center frequency (e.g. Hz). Default is 1000.
- bw** : float, optional  
Fractional bandwidth in frequency domain of pulse (e.g. Hz). Default is 0.5.
- bwr** : float, optional  
Reference level at which fractional bandwidth is calculated (dB). Default is -6.
- tpr** : float, optional  
If *t* is 'cutoff', then the function returns the cutoff time for when the pulse amplitude falls below *tpr* (in dB). Default is -60.
- retquad** : bool, optional  
If True, return the quadrature (imaginary) as well as the real part of the signal. Default is False.
- retenv** : bool, optional  
If True, return the envelope of the signal. Default is False.

**Returns**

- yI** : ndarray  
Real part of signal. Always returned.
- yQ** : ndarray  
Imaginary part of signal. Only returned if *retquad* is True.
- yenv** : ndarray  
Envelope of signal. Only returned if *retenv* is True.

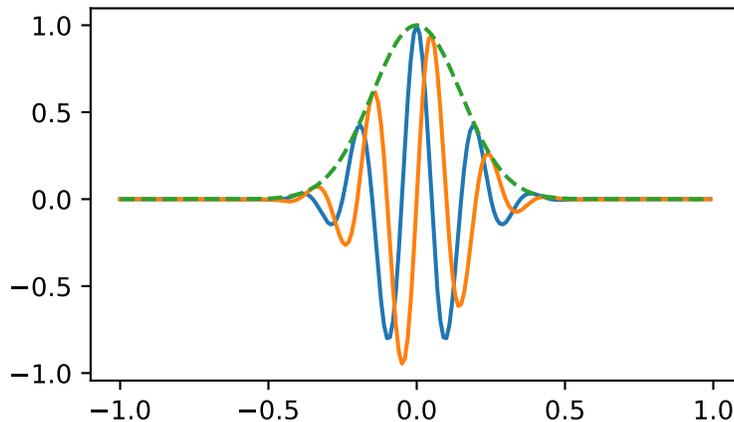

**See also:**

`scipy.signal.morlet`

**Examples**

Plot real component, imaginary component, and envelope for a 5 Hz pulse, sampled at 100 Hz for 2 seconds:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 2 * 100, endpoint=False)
>>> i, q, e = signal.gausspulse(t, fc=5, retquad=True, retenv=True)
>>> plt.plot(t, i, t, q, t, e, '--')
```

`scipy.signal.max_len_seq` (*nbits*, *state=None*, *length=None*, *taps=None*)

Maximum length sequence (MLS) generator.

**Parameters** **nbits** : int

Number of bits to use. Length of the resulting sequence will be  $(2^{**nbits}) - 1$ . Note that generating long sequences (e.g., greater than `nbits == 16`) can take a long time.

**state** : array\_like, optional

If array, must be of length `nbits`, and will be cast to binary (bool) representation. If `None`, a seed of ones will be used, producing a repeatable representation. If `state` is all zeros, an error is raised as this is invalid. Default: `None`.

**length** : int, optional

Number of samples to compute. If `None`, the entire length  $(2^{**nbits}) - 1$  is computed.

**taps** : array\_like, optional

Polynomial taps to use (e.g., `[7, 6, 1]` for an 8-bit sequence). If `None`, taps will be automatically selected (for up to `nbits == 32`).

**Returns**

**seq** : array

Resulting MLS sequence of 0's and 1's.

**state** : array

The final state of the shift register.

**Notes**

The algorithm for MLS generation is generically described in:

[https://en.wikipedia.org/wiki/Maximum\\_length\\_sequence](https://en.wikipedia.org/wiki/Maximum_length_sequence)

The default values for taps are specifically taken from the first option listed for each value of `nbits` in:

[http://www.newwaveinstruments.com/resources/articles/m\\_sequence\\_linear\\_feedback\\_shift\\_register\\_lfsr.htm](http://www.newwaveinstruments.com/resources/articles/m_sequence_linear_feedback_shift_register_lfsr.htm)

New in version 0.15.0.

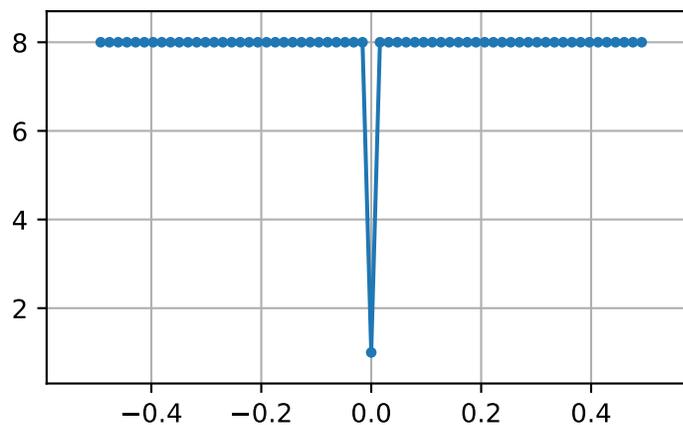

### Examples

MLS uses binary convention:

```
>>> from scipy.signal import max_len_seq
>>> max_len_seq(4)[0]
array([1, 1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0], dtype=int8)
```

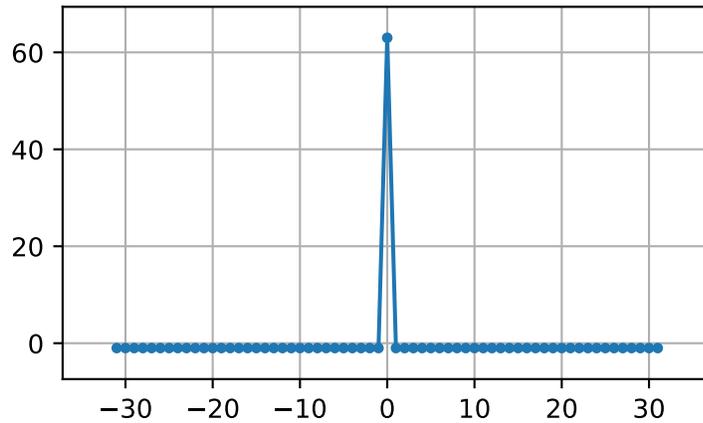

MLS has a white spectrum (except for DC):

```
>>> import matplotlib.pyplot as plt
>>> from numpy.fft import fft, ifft, fftshift, fftfreq
>>> seq = max_len_seq(6)[0]*2-1 # +1 and -1
>>> spec = fft(seq)
>>> N = len(seq)
>>> plt.plot(fftshift(fftfreq(N)), fftshift(np.abs(spec)), '-.')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

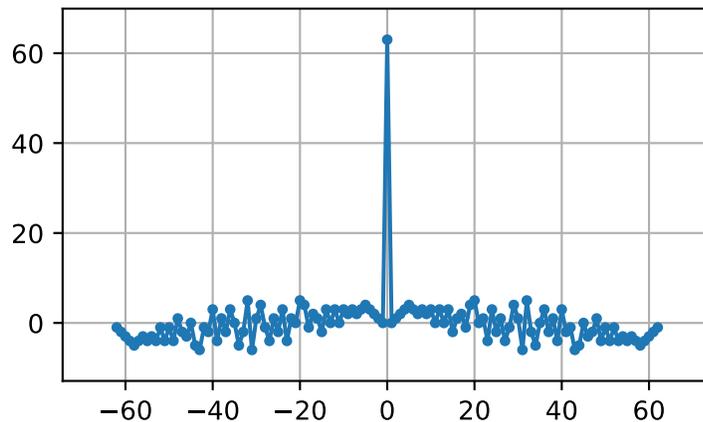

Circular autocorrelation of MLS is an impulse:

```
>>> acorrirc = ifft(spec * np.conj(spec)).real
>>> plt.figure()
>>> plt.plot(np.arange(-N/2+1, N/2+1), fftshift(acorrirc), '-.')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

Linear autocorrelation of MLS is approximately an impulse:

```
>>> acorr = np.correlate(seq, seq, 'full')
>>> plt.figure()
>>> plt.plot(np.arange(-N+1, N), acorr, '-.')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

`scipy.signal.sawtooth`(*t*, *width*=1)

Return a periodic sawtooth or triangle waveform.

The sawtooth waveform has a period  $2\pi$ , rises from -1 to 1 on the interval 0 to  $\text{width}\cdot 2\pi$ , then drops from 1 to -1 on the interval  $\text{width}\cdot 2\pi$  to  $2\pi$ . *width* must be in the interval [0, 1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

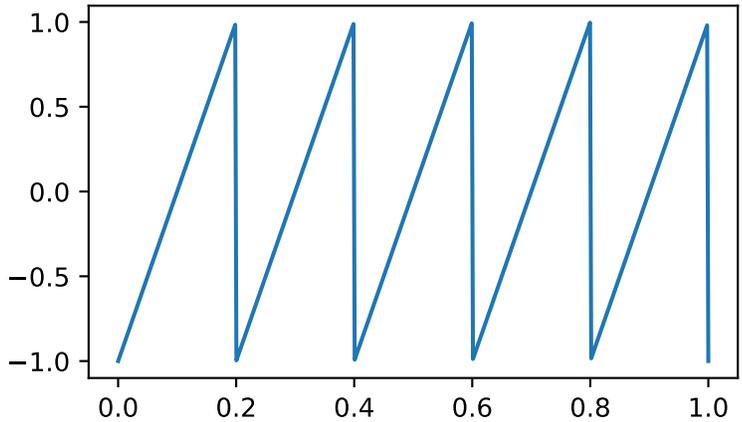

*Parameters*    *t*: array\_like

Time.  
**width** : array\_like, optional  
 Width of the rising ramp as a proportion of the total cycle. Default is 1, producing a rising ramp, while 0 produces a falling ramp. *width* = 0.5 produces a triangle wave. If an array, causes wave shape to change over time, and must be the same length as *t*.  
**Returns** *y* : ndarray  
 Output array containing the sawtooth waveform.

**Examples**

A 5 Hz waveform sampled at 500 Hz for 1 second:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500)
>>> plt.plot(t, signal.sawtooth(2 * np.pi * 5 * t))
```

`scipy.signal.square(t, duty=0.5)`  
 Return a periodic square-wave waveform.

The square wave has a period  $2\pi$ , has value +1 from 0 to  $2\pi \cdot \text{duty}$  and -1 from  $2\pi \cdot \text{duty}$  to  $2\pi$ . *duty* must be in the interval [0,1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

**Parameters** *t* : array\_like  
 The input time array.  
*duty* : array\_like, optional  
 Duty cycle. Default is 0.5 (50% duty cycle). If an array, causes wave shape to change over time, and must be the same length as *t*.  
**Returns** *y* : ndarray  
 Output array containing the square waveform.

**Examples**

A 5 Hz waveform sampled at 500 Hz for 1 second:

```

>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500, endpoint=False)
>>> plt.plot(t, signal.square(2 * np.pi * 5 * t))
>>> plt.ylim(-2, 2)

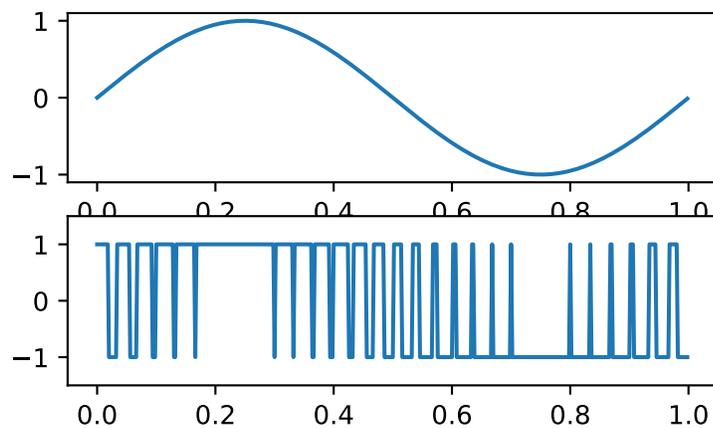

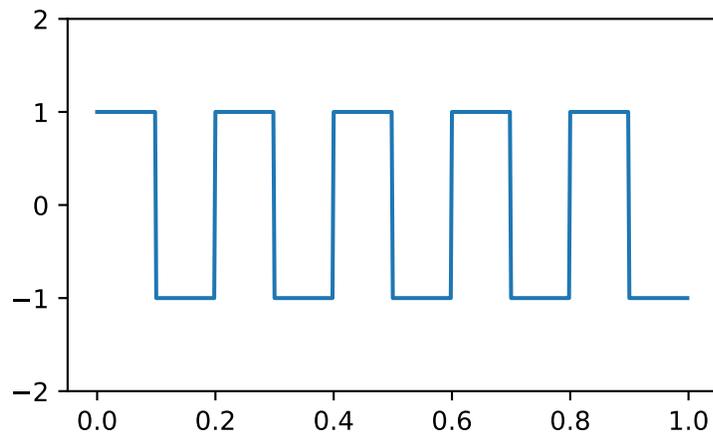

```

A pulse-width modulated sine wave:

```

>>> plt.figure()
>>> sig = np.sin(2 * np.pi * t)
>>> pwm = signal.square(2 * np.pi * 30 * t, duty=(sig + 1)/2)
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, sig)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, pwm)
>>> plt.ylim(-1.5, 1.5)

```

`scipy.signal.sweep_poly(t, poly, phi=0)`

Frequency-swept cosine generator, with a time-dependent frequency.

This function generates a sinusoidal function whose instantaneous frequency varies with time. The frequency at time  $t$  is given by the polynomial  $poly$ .

**Parameters** `t` : ndarray

Times at which to evaluate the waveform.

**poly** : 1-D array\_like or instance of `numpy.poly1d`

The desired frequency expressed as a polynomial. If  $poly$  is a list or ndarray of length  $n$ , then the elements of  $poly$  are the coefficients of the polynomial, and the instantaneous frequency is

$$f(t) = poly[0]*t^{n-1} + poly[1]*t^{n-2} + \dots + poly[n-1]$$

If  $poly$  is an instance of `numpy.poly1d`, then the instantaneous frequency is

$$f(t) = poly(t)$$

**phi** : float, optional

Phase offset, in degrees, Default: 0.

**Returns**

**sweep\_poly** : ndarray

A numpy array containing the signal evaluated at  $t$  with the requested time-varying frequency. More precisely, the function returns  $\cos(\text{phase} + (\pi/180)*\text{phi})$ , where  $phase$  is the integral (from 0 to  $t$ ) of  $2 * \pi * f(t)$ ;  $f(t)$  is defined above.

**See also:**

`chirp`

**Notes**

New in version 0.8.0.

If  $poly$  is a list or ndarray of length  $n$ , then the elements of  $poly$  are the coefficients of the polynomial, and the instantaneous frequency is:

$$f(t) = poly[0]*t^{n-1} + poly[1]*t^{n-2} + \dots + poly[n-1]$$

If  $poly$  is an instance of `numpy.poly1d`, then the instantaneous frequency is:

$$f(t) = poly(t)$$

Finally, the output  $s$  is:

$$\cos(\text{phase} + (\pi/180)*\text{phi})$$

where  $phase$  is the integral from 0 to  $t$  of  $2 * \pi * f(t)$ ,  $f(t)$  as defined above.

**Examples**

Compute the waveform with instantaneous frequency:

```
f(t) = 0.025*t**3 - 0.36*t**2 + 1.25*t + 2
```

over the interval  $0 \leq t \leq 10$ .

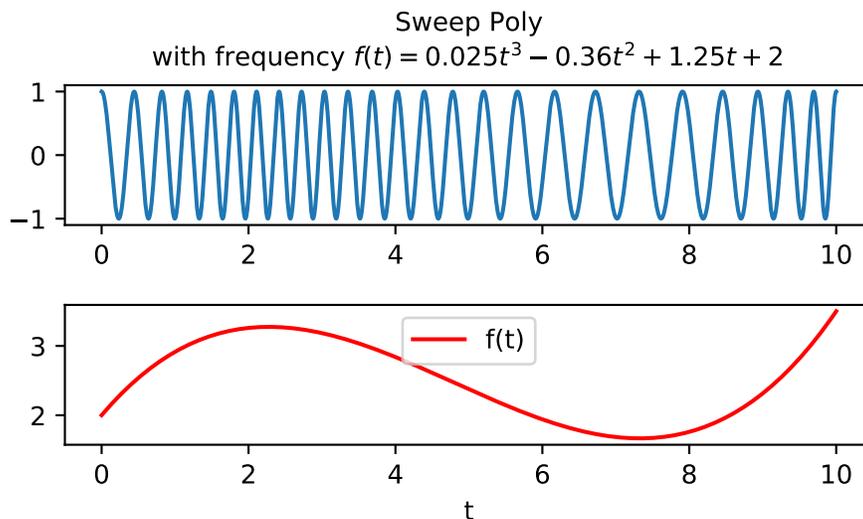

```
>>> from scipy.signal import sweep_poly
>>> p = np.poly1d([0.025, -0.36, 1.25, 2.0])
>>> t = np.linspace(0, 10, 5001)
>>> w = sweep_poly(t, p)
```

Plot it:

```

>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, w)
>>> plt.title("Sweep Poly\nwith frequency " +
...          "$f(t) = 0.025t^3 - 0.36t^2 + 1.25t + 2$")
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, p(t), 'r', label='f(t)')
>>> plt.legend()
>>> plt.xlabel('t')
>>> plt.tight_layout()
>>> plt.show()

```

`scipy.signal.unit_impulse` (*shape*, *idx=None*, *dtype=<type 'float'>*)

Unit impulse signal (discrete delta function) or unit basis vector.

**Parameters**    **shape** : int or tuple of int

Number of samples in the output (1-D), or a tuple that represents the shape of the output (N-D).

**idx** : None or int or tuple of int or 'mid', optional

Index at which the value is 1. If None, defaults to the 0th element. If `idx='mid'`, the impulse will be centered at `shape // 2` in all dimensions. If an int, the impulse will be at `idx` in all dimensions.

**dtype** : data-type, optional

The desired data-type for the array, e.g., `numpy.int8`. Default is `numpy.float64`.

**Returns**        **y** : ndarray

Output array containing an impulse signal.

### Notes

The 1D case is also known as the Kronecker delta.

New in version 0.19.0.

### Examples

An impulse at the 0th element ( $\delta[n]$ ):

```
>>> from scipy import signal
>>> signal.unit_impulse(8)
array([ 1.,  0.,  0.,  0.,  0.,  0.,  0.,  0.])
```

Impulse offset by 2 samples ( $\delta[n - 2]$ ):

```
>>> signal.unit_impulse(7, 2)
array([ 0.,  0.,  1.,  0.,  0.,  0.,  0.])
```

2-dimensional impulse, centered:

```
>>> signal.unit_impulse((3, 3), 'mid')
array([[ 0.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  0.]])
```

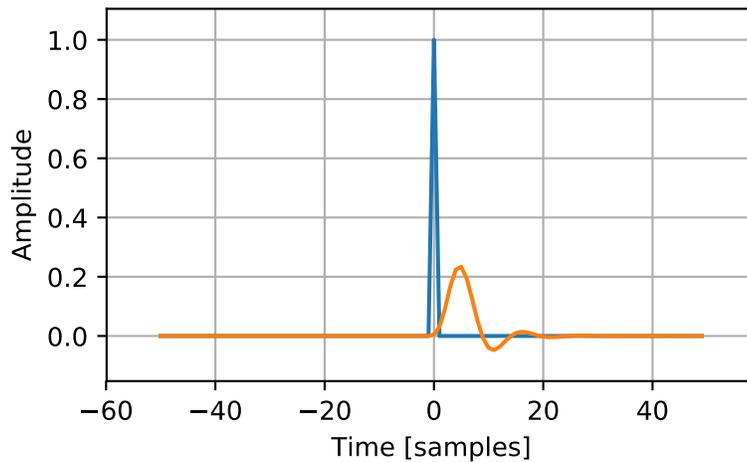

Impulse at (2, 2), using broadcasting:

```
>>> signal.unit_impulse((4, 4), 2)
array([[ 0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.],
       [ 0.,  0.,  0.,  0.]])
```

Plot the impulse response of a 4th-order Butterworth lowpass filter:

```
>>> imp = signal.unit_impulse(100, 'mid')
>>> b, a = signal.butter(4, 0.2)
>>> response = signal.lfilter(b, a, imp)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(np.arange(-50, 50), imp)
>>> plt.plot(np.arange(-50, 50), response)
>>> plt.margins(0.1, 0.1)
>>> plt.xlabel('Time [samples]')
>>> plt.ylabel('Amplitude')
>>> plt.grid(True)
>>> plt.show()
```

### 5.20.10 Window functions

<code>get_window(window, Nx[, fftbins])</code>	Return a window.
<code>barthann(M[, sym])</code>	Return a modified Bartlett-Hann window.
<code>bartlett(M[, sym])</code>	Return a Bartlett window.
<code>blackman(M[, sym])</code>	Return a Blackman window.
<code>blackmanharris(M[, sym])</code>	Return a minimum 4-term Blackman-Harris window.
<code>bohman(M[, sym])</code>	Return a Bohman window.
<code>boxcar(M[, sym])</code>	Return a boxcar or rectangular window.
<code>chebwin(M, at[, sym])</code>	Return a Dolph-Chebyshev window.
<code>cosine(M[, sym])</code>	Return a window with a simple cosine shape.
<code>exponential(M[, center, tau, sym])</code>	Return an exponential (or Poisson) window.
<code>flattop(M[, sym])</code>	Return a flat top window.
<code>gaussian(M, std[, sym])</code>	Return a Gaussian window.
<code>general_gaussian(M, p, sig[, sym])</code>	Return a window with a generalized Gaussian shape.
<code>hamming(M[, sym])</code>	Return a Hamming window.
<code>hann(M[, sym])</code>	Return a Hann window.
<code>hanning(M[, sym])</code>	Return a Hann window.
<code>kaiser(M, beta[, sym])</code>	Return a Kaiser window.
<code>nutall(M[, sym])</code>	Return a minimum 4-term Blackman-Harris window according to Nuttall.
<code>parzen(M[, sym])</code>	Return a Parzen window.
<code>slepian(M, width[, sym])</code>	Return a digital Slepian (DPSS) window.
<code>triang(M[, sym])</code>	Return a triangular window.
<code>tukey(M[, alpha, sym])</code>	Return a Tukey window, also known as a tapered cosine window.

`scipy.signal.get_window(window, Nx, fftbins=True)`

Return a window.

**Parameters** `window` : string, float, or tuple

The type of window to create. See below for more details.

**Nx** : int  
 The number of samples in the window.

**fftbins** : bool, optional  
 If True (default), create a “periodic” window, ready to use with *fftshift* and be multiplied by the result of an FFT (see also *fftpack.fftfreq*). If False, create a “symmetric” window, for use in filter design.

**Returns**     **get\_window** : ndarray  
 Returns a window of length *Nx* and type *window*

### Notes

Window types:

*boxcar*, *triang*, *blackman*, *hamming*, *hann*, *bartlett*, *flattop*, *parzen*, *bohman*, *blackmanharris*, *nutall*, *barthann*, *kaiser* (needs beta), *gaussian* (needs standard deviation), *general\_gaussian* (needs power, width), *slepian* (needs width), *chebwin* (needs attenuation), *exponential* (needs decay scale), *tukey* (needs taper fraction)

If the window requires no parameters, then *window* can be a string.

If the window requires parameters, then *window* must be a tuple with the first argument the string name of the window, and the next arguments the needed parameters.

If *window* is a floating point number, it is interpreted as the beta parameter of the *kaiser* window.

Each of the window types listed above is also the name of a function that can be called directly to create a window of that type.

### Examples

```

>>> from scipy import signal
>>> signal.get_window('triang', 7)
array([ 0.125,  0.375,  0.625,  0.875,  0.875,  0.625,  0.375])
>>> signal.get_window(('kaiser', 4.0), 9)
array([ 0.08848053,  0.29425961,  0.56437221,  0.82160913,  0.97885093,
        0.97885093,  0.82160913,  0.56437221,  0.29425961])
>>> signal.get_window(4.0, 9)
array([ 0.08848053,  0.29425961,  0.56437221,  0.82160913,  0.97885093,
        0.97885093,  0.82160913,  0.56437221,  0.29425961])
    
```

`scipy.signal.barthann` (*M*, *sym=True*)

Return a modified Bartlett-Hann window.

**Parameters**     **M** : int  
 Number of points in the output window. If zero or less, an empty array is returned.

**sym** : bool, optional  
 When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**     **w** : ndarray  
 The window, with the maximum value normalized to 1 (though the value 1 does not appear if *M* is even and *sym* is True).

### Examples

Plot the window and its frequency response:

```

>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
    
```

```

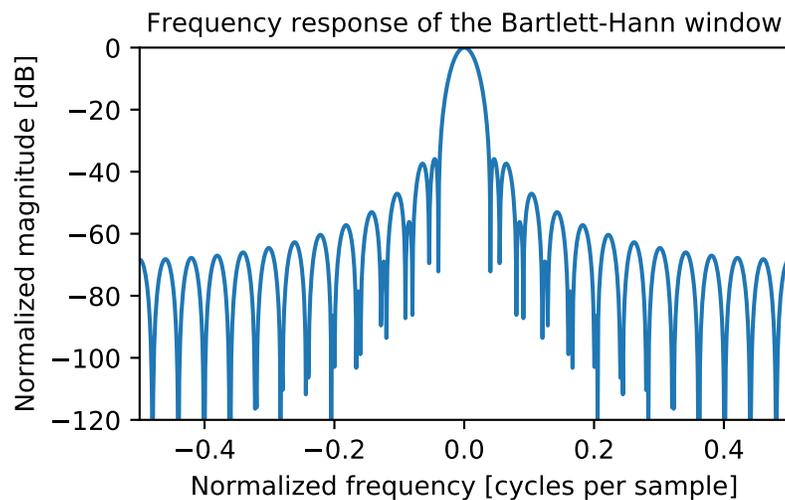

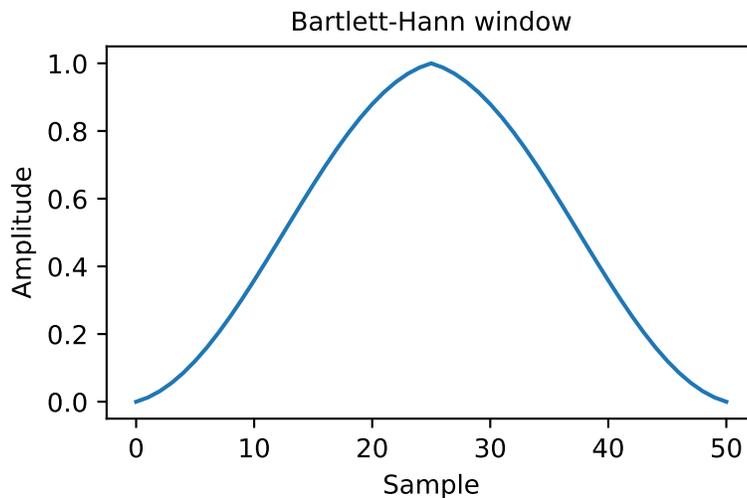

>>> window = signal.bartlett(51)
>>> plt.plot(window)
>>> plt.title("Bartlett-Hann window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

```

```

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Bartlett-Hann window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")

```

`scipy.signal.bartlett` ( $M$ ,  $sym=True$ )

Return a Bartlett window.

The Bartlett window is very similar to a triangular window, except that the end points are at zero. It is often used in signal processing for tapering a signal, without generating too much ripple in the frequency domain.

**Parameters**

**M** : int  
Number of points in the output window. If zero or less, an empty array is returned.

**sym** : bool, optional  
When True (default), generates a symmetric window, for use in filter design.  
When False, generates a periodic window, for use in spectral analysis.

**Returns**

**w** : ndarray  
The triangular window, with the first and last samples equal to zero and the maximum value normalized to 1 (though the value 1 does not appear if *M* is even and *sym* is True).

**See also:**

**triang** A triangular window that does not touch zero at the ends

**Notes**

The Bartlett window is defined as

$$w(n) = \frac{2}{M-1} \left( \frac{M-1}{2} - \left| n - \frac{M-1}{2} \right| \right)$$

Most references to the Bartlett window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. Note that convolution with this window produces linear interpolation. It is also known as an apodization (which means "removing the foot", i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function. The Fourier transform of the Bartlett is the product of two sinc functions. Note the excellent discussion in Kanasewich. [R225]

**References**

[R224], [R225], [R226], [R227], [R228]

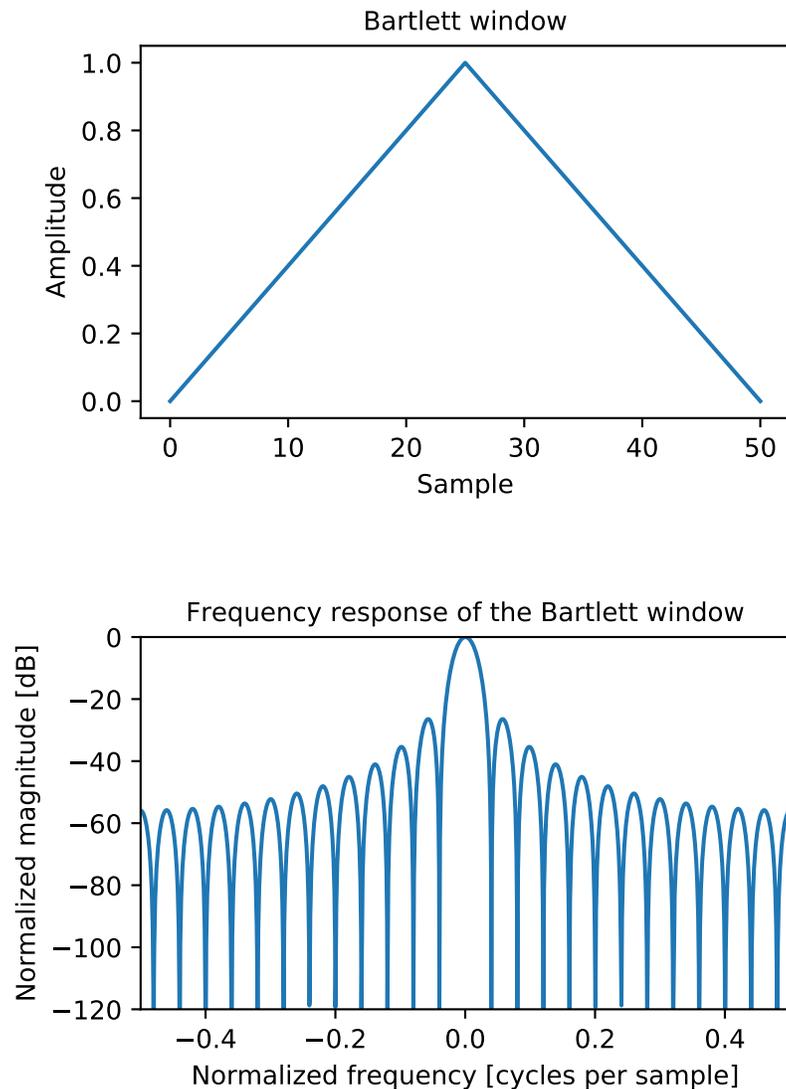

**Examples**

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.bartlett(51)
>>> plt.plot(window)
>>> plt.title("Bartlett window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Bartlett window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.blackman` ( $M$ ,  $sym=True$ )

Return a Blackman window.

The Blackman window is a taper formed by using the first three terms of a summation of cosines. It was designed to have close to the minimal leakage possible. It is close to optimal, only slightly worse than a Kaiser window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

The Blackman window is defined as

$$w(n) = 0.42 - 0.5 \cos(2\pi n/M) + 0.08 \cos(4\pi n/M)$$

The “exact Blackman” window was designed to null out the third and fourth sidelobes, but has discontinuities at the boundaries, resulting in a 6 dB/oct fall-off. This window is an approximation of the “exact” window, which does not null the sidelobes as well, but is smooth at the edges, improving the fall-off rate to 18 dB/oct. [R238]

Most references to the Blackman window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function. It is known as a “near optimal” tapering function, almost as good (by some measures) as the Kaiser window.

### References

[R236], [R237], [R238]

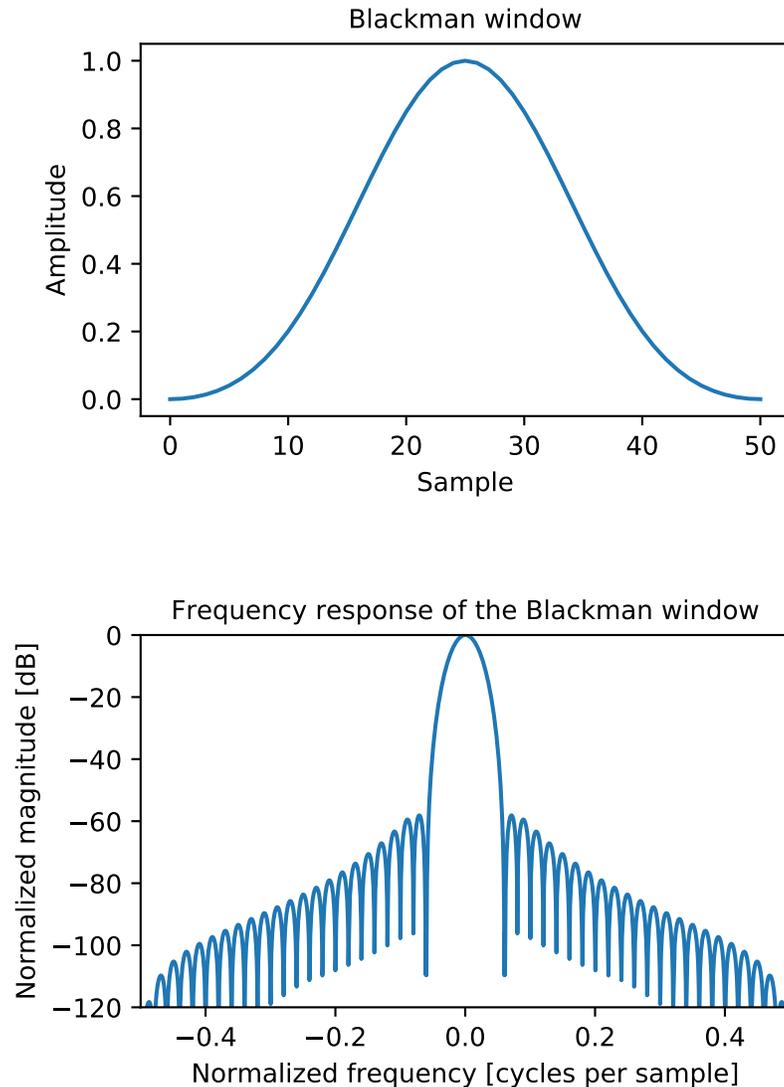

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.blackman(51)
>>> plt.plot(window)
>>> plt.title("Blackman window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Blackman window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.blackmanharris` ( $M$ ,  $sym=True$ )  
 Return a minimum 4-term Blackman-Harris window.

**Parameters**     $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**         $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

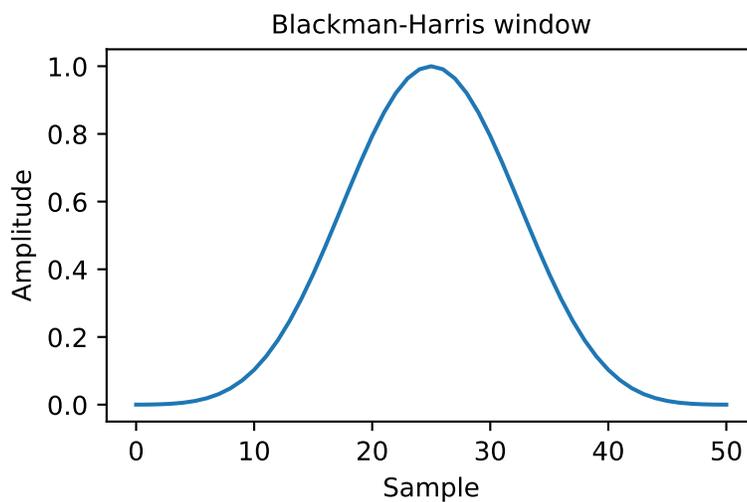

### Examples

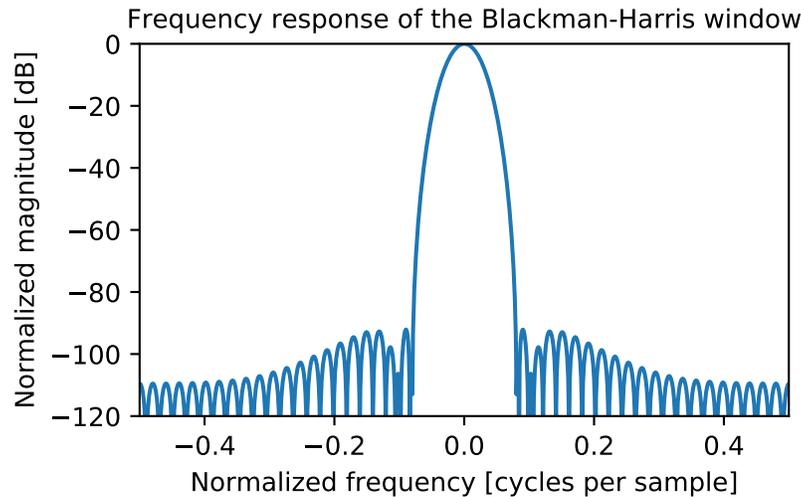

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.blackmanharris(51)
>>> plt.plot(window)
>>> plt.title("Blackman-Harris window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Blackman-Harris window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.bohman` ( $M$ ,  $sym=True$ )

Return a Bohman window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

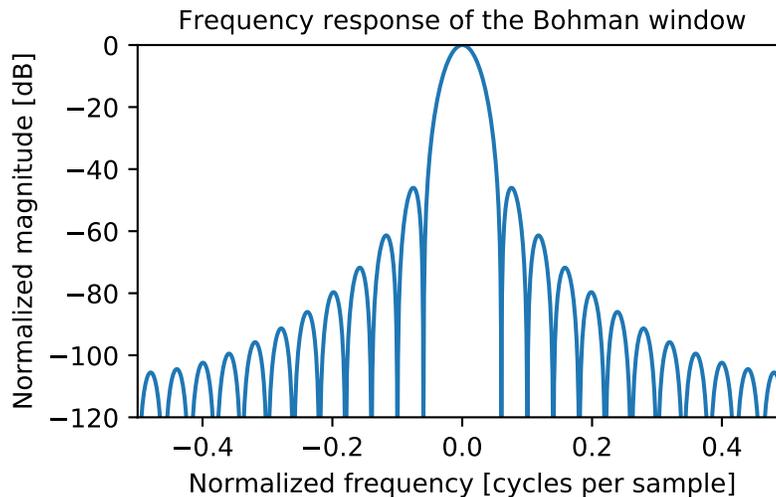

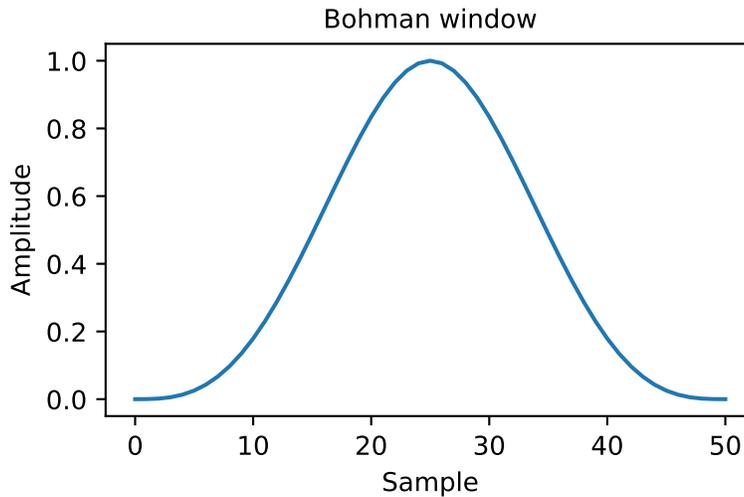

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.bohman(51)
>>> plt.plot(window)
>>> plt.title("Bohman window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Bohman window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.boxcar` ( $M$ ,  $sym=True$ )

Return a boxcar or rectangular window.

Also known as a rectangular window or Dirichlet window, this is equivalent to no window at all.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

Whether the window is symmetric. (Has no effect for boxcar.)

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1.

### Examples

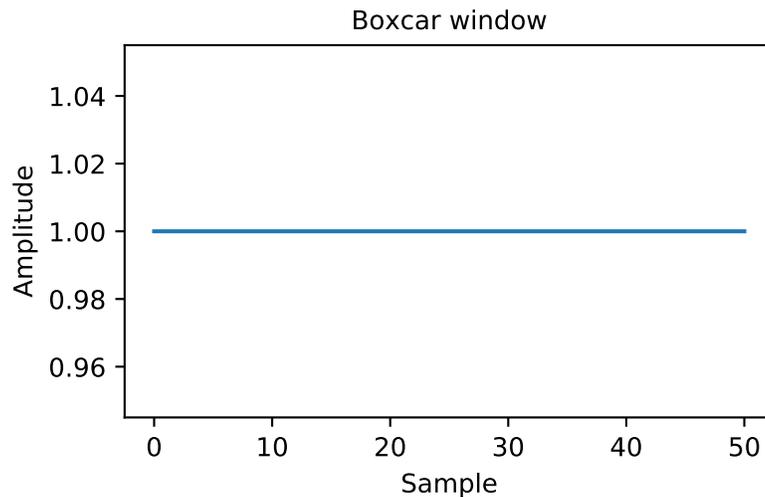

Plot the window and its frequency response:

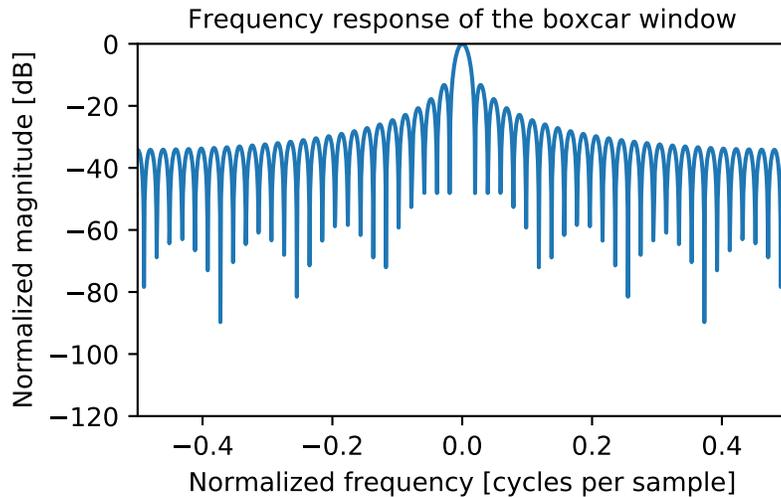

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
```

```
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.boxcar(51)
>>> plt.plot(window)
>>> plt.title("Boxcar window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the boxcar window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.chebwin` ( $M$ ,  $at$ ,  $sym=True$ )

Return a Dolph-Chebyshev window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$at$  : float

Attenuation (in dB).

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value always normalized to 1

### Notes

This window optimizes for the narrowest main lobe width for a given order  $M$  and sidelobe equiripple attenuation  $at$ , using Chebyshev polynomials. It was originally developed by Dolph to optimize the directionality of radio antenna arrays.

Unlike most windows, the Dolph-Chebyshev is defined in terms of its frequency response:

$$W(k) = \frac{\cos\{M \cos^{-1}[\beta \cos(\frac{\pi k}{M})]\}}{\cosh[M \cosh^{-1}(\beta)]}$$

where

$$\beta = \cosh \left[ \frac{1}{M} \cosh^{-1}(10^{\frac{A}{20}}) \right]$$

and  $0 \leq \text{abs}(k) \leq M-1$ .  $A$  is the attenuation in decibels ( $at$ ).

The time domain window is then generated using the IFFT, so power-of-two  $M$  are the fastest to generate, and prime number  $M$  are the slowest.

The equiripple condition in the frequency domain creates impulses in the time domain, which appear at the ends of the window.

### References

[R239], [R240], [R241]

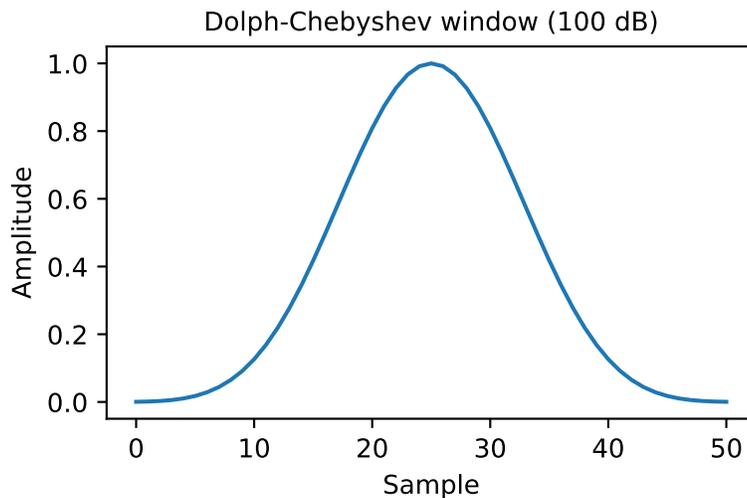

### Examples

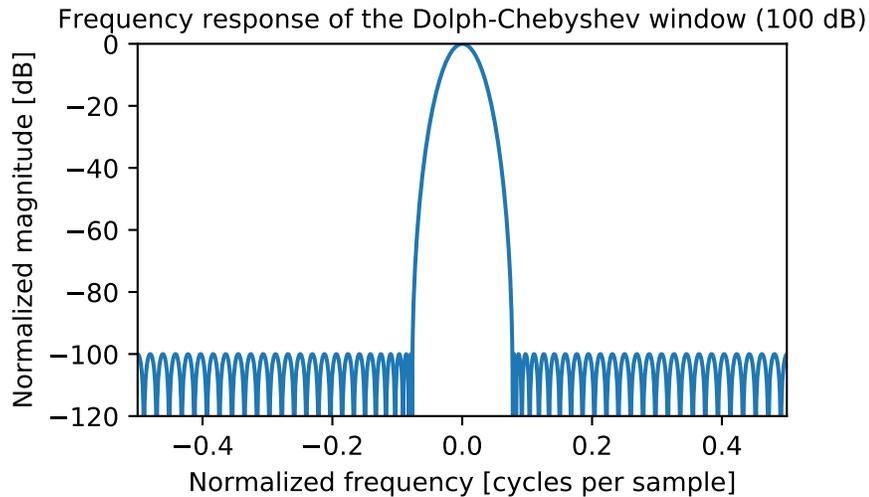

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.chebwin(51, at=100)
>>> plt.plot(window)
>>> plt.title("Dolph-Chebyshev window (100 dB)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Dolph-Chebyshev window (100 dB)")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.cosine` ( $M$ ,  $sym=True$ )

Return a window with a simple cosine shape.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

New in version 0.13.0.

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

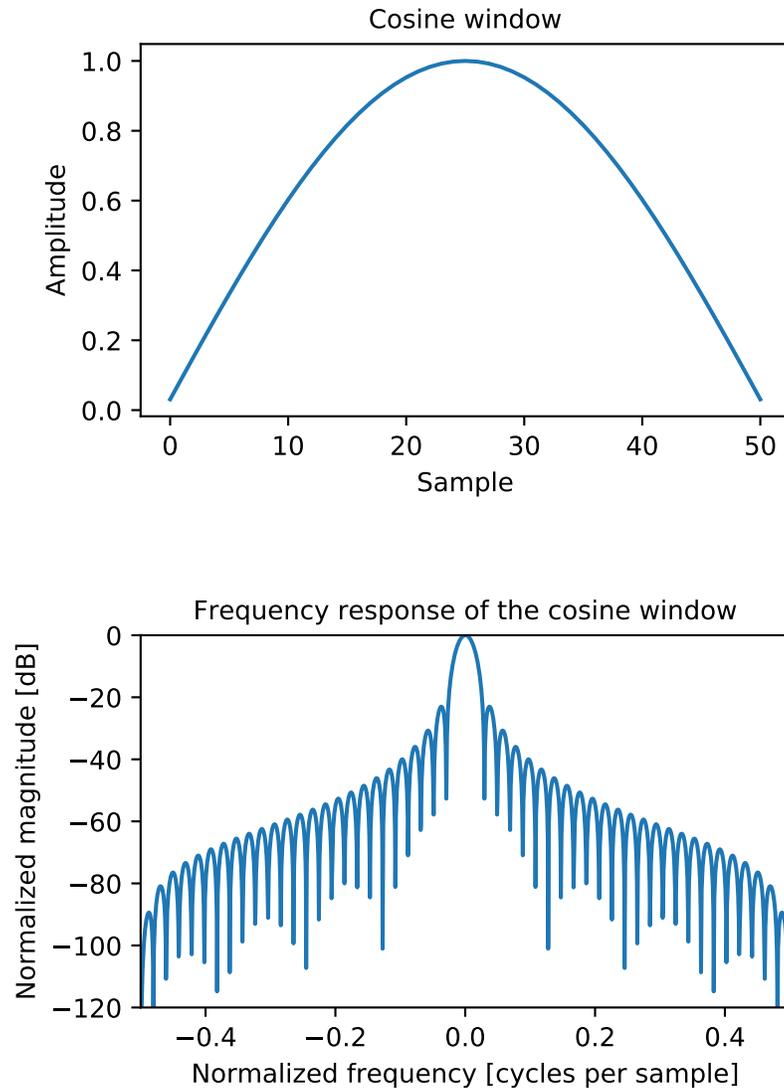

```
>>> window = signal.cosine(51)
>>> plt.plot(window)
>>> plt.title("Cosine window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the cosine window")
```

```

>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
>>> plt.show()

```

`scipy.signal.exponential` ( $M$ , *center=None*, *tau=1.0*, *sym=True*)

Return an exponential (or Poisson) window.

**Parameters**  $M$ : int

Number of points in the output window. If zero or less, an empty array is returned.

**center**: float, optional

Parameter defining the center location of the window function. The default value if not given is  $center = (M-1) / 2$ . This parameter must take its default value for symmetric windows.

**tau**: float, optional

Parameter defining the decay. For  $center = 0$  use  $tau = -(M-1) / \ln(x)$  if  $x$  is the fraction of the window remaining at the end.

**sym** : bool, optional  
 When True (default), generates a symmetric window, for use in filter design.  
 When False, generates a periodic window, for use in spectral analysis.

**Returns** **w** : ndarray  
 The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and *sym* is True).

**Notes**

The Exponential window is defined as

$$w(n) = e^{-|n-center|/\tau}$$

**References**

S. Gade and H. Herlufsen, “Windows to FFT analysis (Part I)”, Technical Review 3, Bruel & Kjaer, 1987.

**Examples**

Plot the symmetric window and its frequency response:

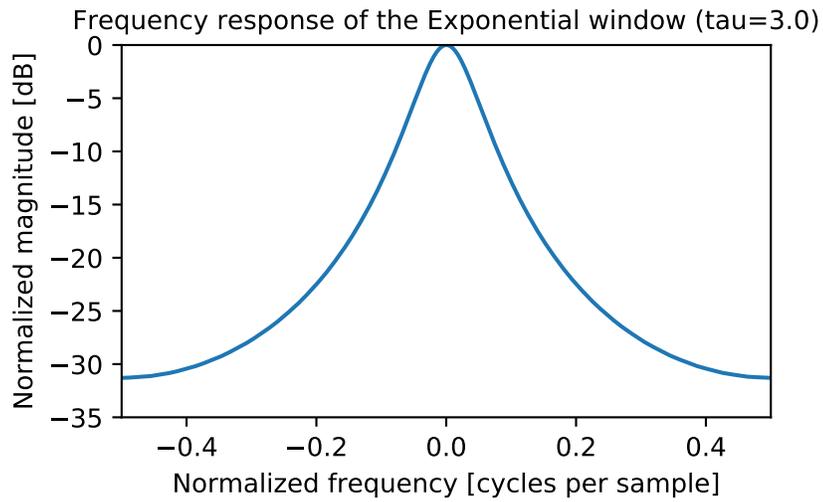

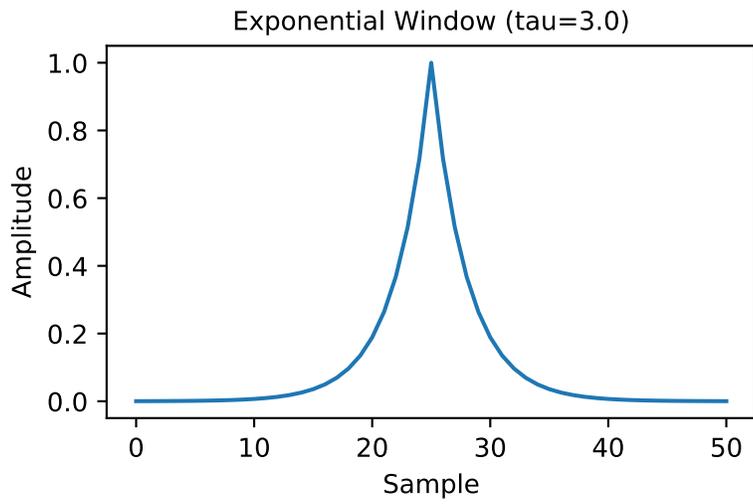

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

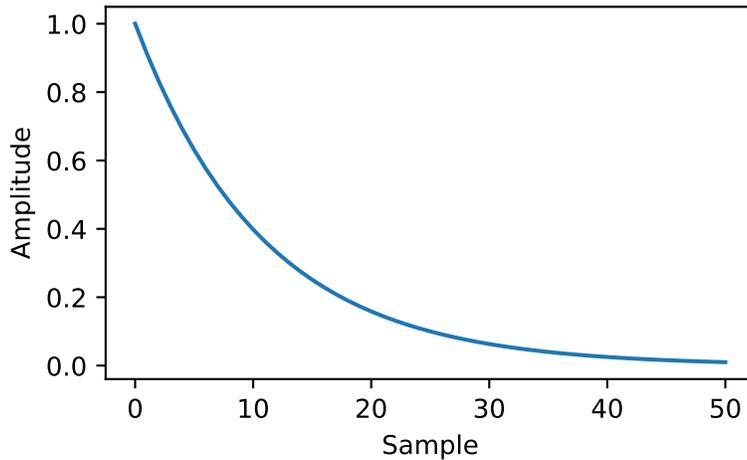

```
>>> M = 51
>>> tau = 3.0
>>> window = signal.exponential(M, tau=tau)
>>> plt.plot(window)
>>> plt.title("Exponential Window (tau=3.0)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -35, 0])
>>> plt.title("Frequency response of the Exponential window (tau=3.0)")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

This function can also generate non-symmetric windows:

```
>>> tau2 = -(M-1) / np.log(0.01)
>>> window2 = signal.exponential(M, 0, tau2, False)
>>> plt.figure()
>>> plt.plot(window2)
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

`scipy.signal.flattop` ( $M$ ,  $sym=True$ )

Return a flat top window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

Flat top windows are used for taking accurate measurements of signal amplitude in the frequency domain, with minimal scalloping error from the center of a frequency bin to its edges, compared to others. This is a 5th-order cosine window, with the 5 terms optimized to make the main lobe maximally flat. [R257]

### References

[R257]

### Examples

Plot the window and its frequency response:

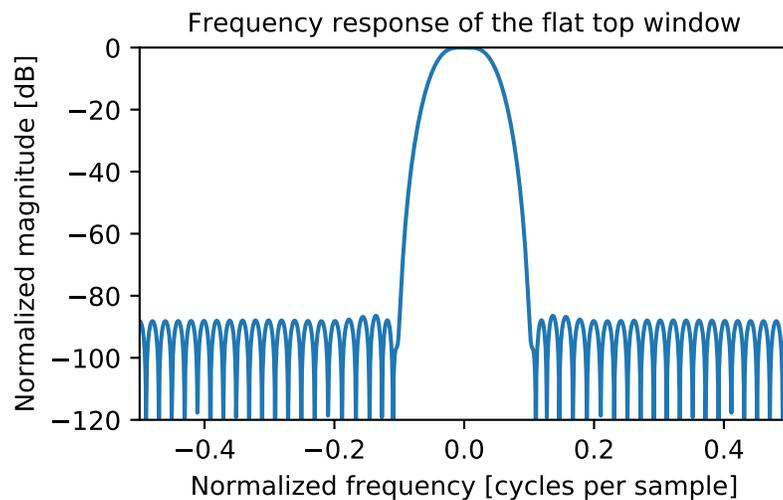

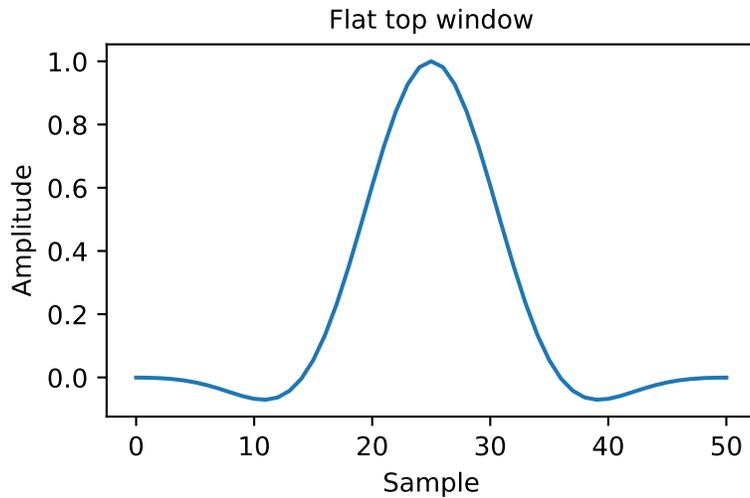

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.flattop(51)
>>> plt.plot(window)
>>> plt.title("Flat top window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the flat top window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")

```

`scipy.signal.gaussian` ( $M$ ,  $std$ ,  $sym=True$ )

Return a Gaussian window.

**Parameters**  $M$ : int

Number of points in the output window. If zero or less, an empty array is returned.

$std$ : float

The standard deviation, sigma.

**sym** : bool, optional  
 When True (default), generates a symmetric window, for use in filter design.  
 When False, generates a periodic window, for use in spectral analysis.

**Returns** **w** : ndarray  
 The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and *sym* is True).

**Notes**

The Gaussian window is defined as

$$w(n) = e^{-\frac{1}{2}\left(\frac{n}{\sigma}\right)^2}$$

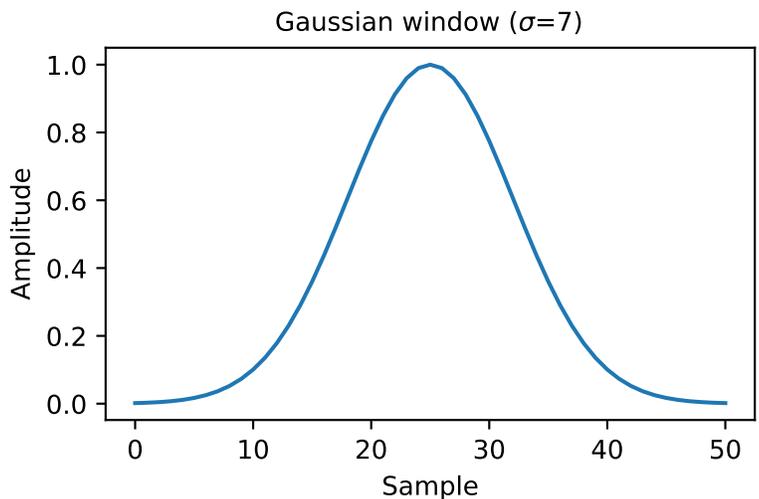

**Examples**

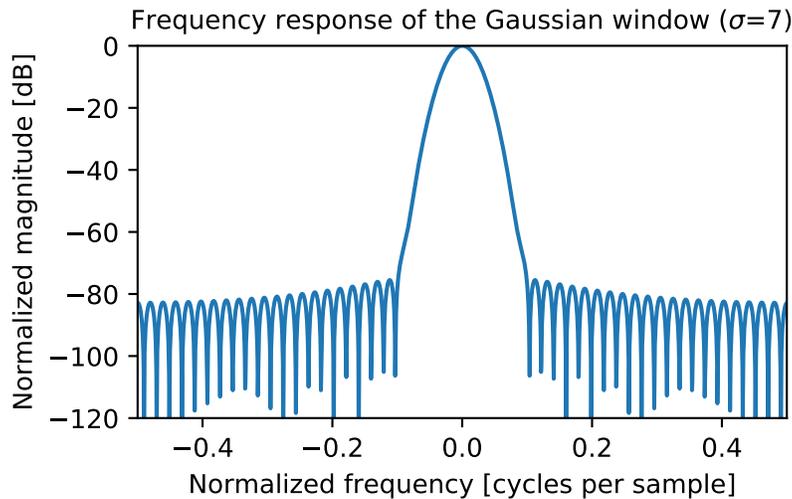

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.gaussian(51, std=7)
>>> plt.plot(window)
>>> plt.title(r"Gaussian window ( $\sigma=7$ )")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title(r"Frequency response of the Gaussian window ( $\sigma=7$ )")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.general_gaussian` ( $M, p, sig, sym=True$ )

Return a window with a generalized Gaussian shape.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$p$  : float

Shape parameter.  $p = 1$  is identical to *gaussian*,  $p = 0.5$  is the same shape as the Laplace distribution.

$sig$  : float

The standard deviation, sigma.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

The generalized Gaussian window is defined as

$$w(n) = e^{-\frac{1}{2} \left| \frac{n}{\sigma} \right|^{2p}}$$

the half-power point is at

$$(2 \log(2))^{1/(2p)} \sigma$$

### Examples

Plot the window and its frequency response:

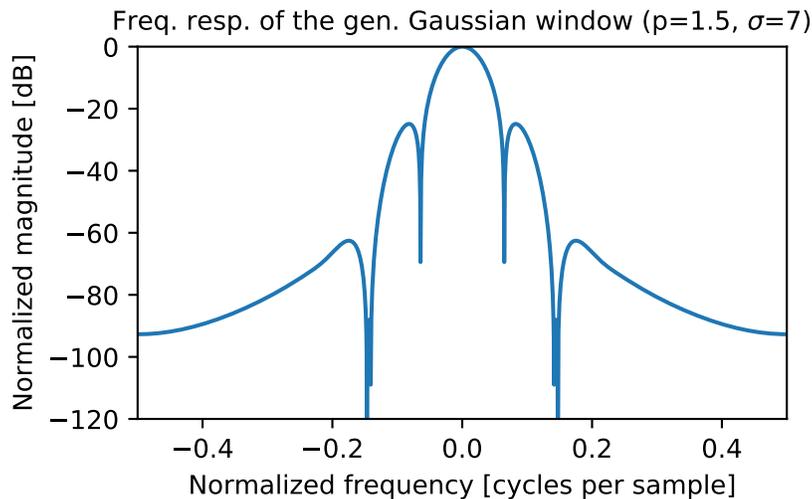

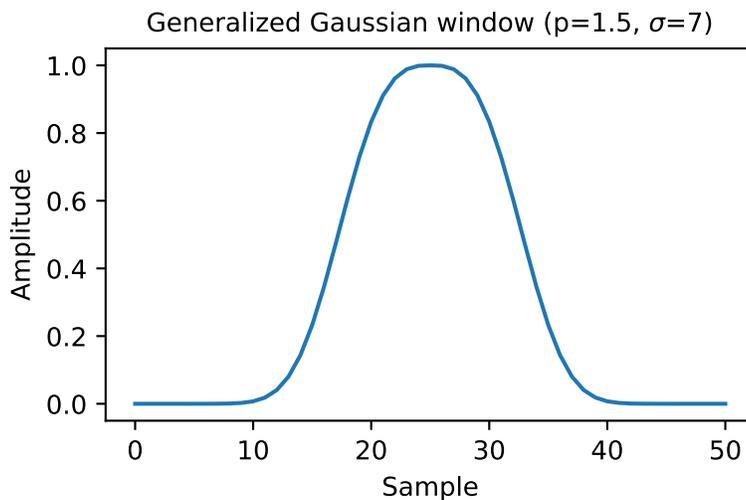

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```

>>> window = signal.general_gaussian(51, p=1.5, sig=7)
>>> plt.plot(window)
>>> plt.title(r"Generalized Gaussian window (p=1.5, $\sigma$=7)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
    
```

```

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max()))))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title(r"Freq. resp. of the gen. Gaussian "
...         r"window (p=1.5, $\sigma$=7)")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
    
```

`scipy.signal.hamming` ( $M$ ,  $sym=True$ )

Return a Hamming window.

The Hamming window is a taper formed by using a raised cosine with non-zero endpoints, optimized to minimize the nearest side lobe.

**Parameters**

- M** : int  
Number of points in the output window. If zero or less, an empty array is returned.
- sym** : bool, optional  
When True (default), generates a symmetric window, for use in filter design.  
When False, generates a periodic window, for use in spectral analysis.

**Returns**

- w** : ndarray  
The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

The Hamming window is defined as

$$w(n) = 0.54 - 0.46 \cos\left(\frac{2\pi n}{M-1}\right) \quad 0 \leq n \leq M-1$$

The Hamming was named for R. W. Hamming, an associate of J. W. Tukey and is described in Blackman and Tukey. It was recommended for smoothing the truncated autocovariance function in the time domain. Most references to the Hamming window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

### References

[R259], [R260], [R261], [R262]

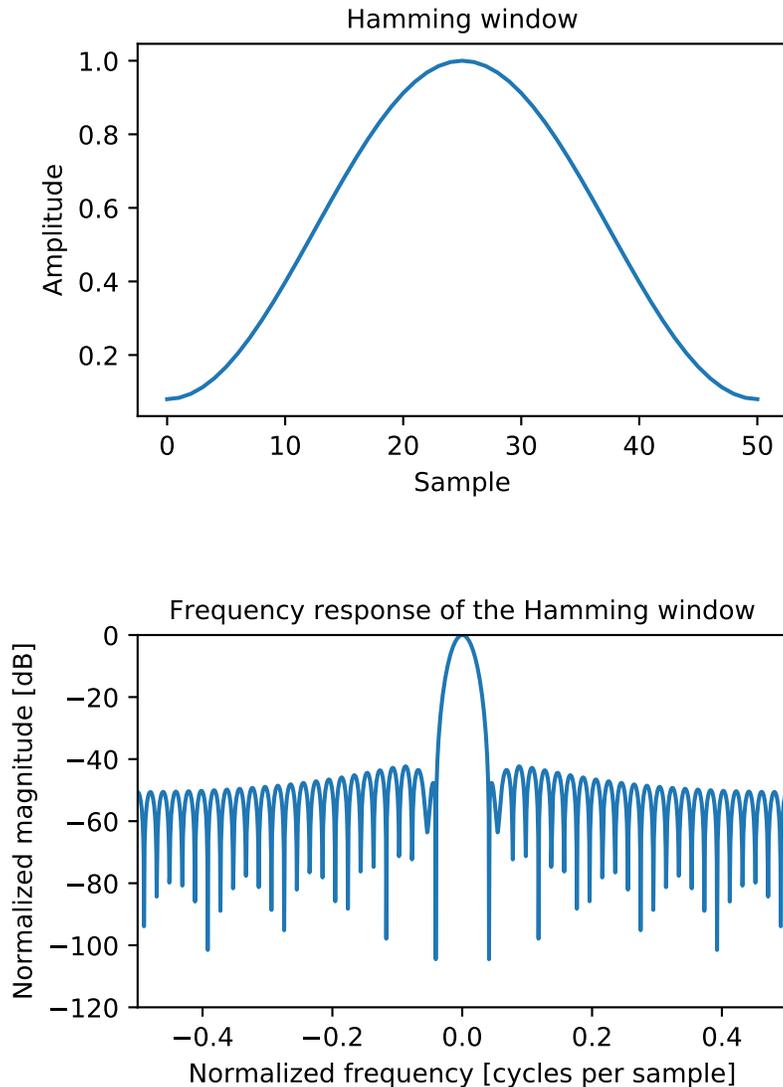

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.hamming(51)
>>> plt.plot(window)
>>> plt.title("Hamming window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Hamming window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.hann` ( $M$ ,  $sym=True$ )

Return a Hann window.

The Hann window is a taper formed by using a raised cosine or sine-squared with ends that touch zero.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

**Notes**

The Hann window is defined as

$$w(n) = 0.5 - 0.5 \cos\left(\frac{2\pi n}{M-1}\right) \quad 0 \leq n \leq M-1$$

The window was named for Julius von Hann, an Austrian meteorologist. It is also known as the Cosine Bell. It is sometimes erroneously referred to as the “Hanning” window, from the use of “hann” as a verb in the original paper and confusion with the very similar Hamming window.

Most references to the Hann window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

**References**

[R263], [R264], [R265], [R266]

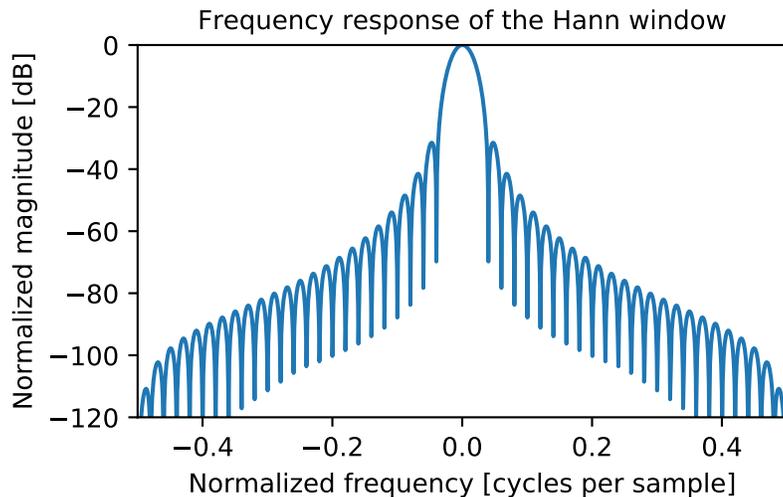

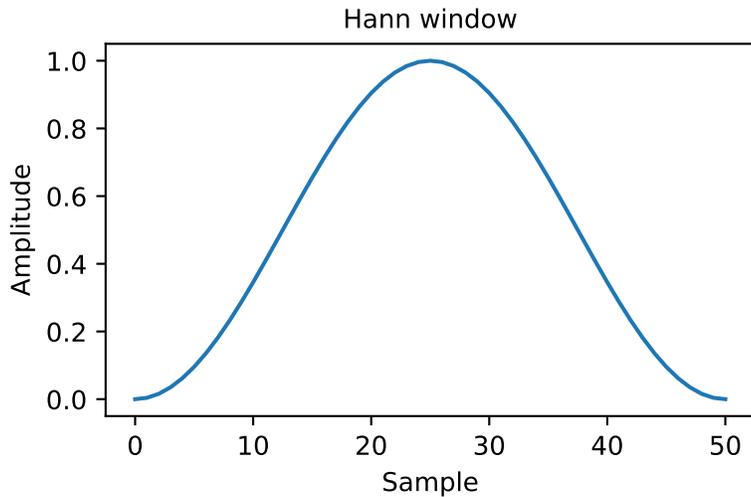

**Examples**

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.hann(51)
>>> plt.plot(window)
>>> plt.title("Hann window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Hann window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.hanning` ( $M$ ,  $sym=True$ )

Return a Hann window.

The Hann window is a taper formed by using a raised cosine or sine-squared with ends that touch zero.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

**Notes**

The Hann window is defined as

$$w(n) = 0.5 - 0.5 \cos\left(\frac{2\pi n}{M-1}\right) \quad 0 \leq n \leq M-1$$

The window was named for Julius von Hann, an Austrian meteorologist. It is also known as the Cosine Bell. It is sometimes erroneously referred to as the “Hanning” window, from the use of “hann” as a verb in the original paper and confusion with the very similar Hamming window.

Most references to the Hann window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

**References**

[R267], [R268], [R269], [R270]

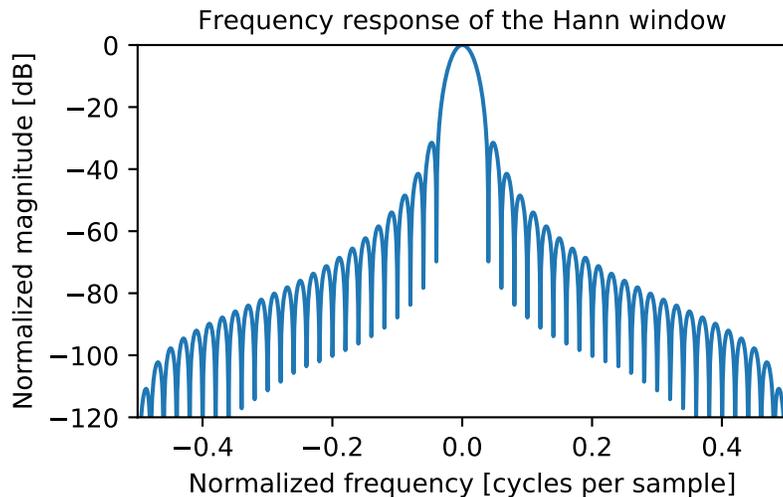

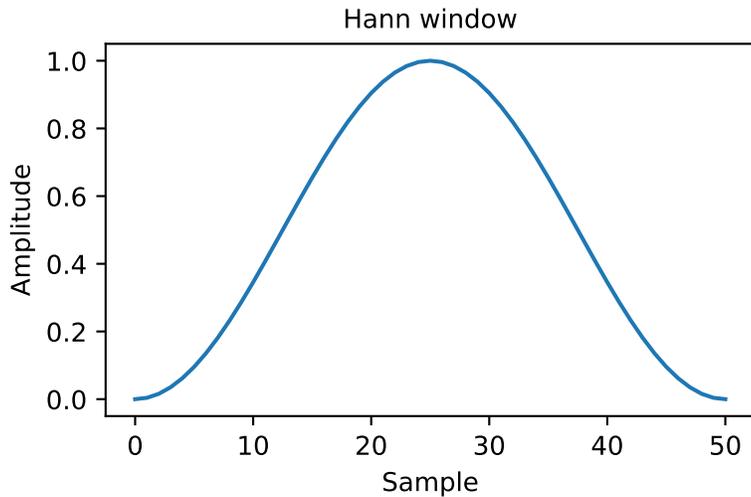

**Examples**

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.hann(51)
>>> plt.plot(window)
>>> plt.title("Hann window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Hann window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.kaiser` ( $M$ ,  $\beta$ ,  $\text{sym}=\text{True}$ )

Return a Kaiser window.

The Kaiser window is a taper formed by using a Bessel function.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$\beta$  : float

Shape parameter, determines trade-off between main-lobe width and side lobe level. As  $\beta$  gets large, the window narrows.

$\text{sym}$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $\text{sym}$  is True).

**Notes**

The Kaiser window is defined as

$$w(n) = I_0 \left( \beta \sqrt{1 - \frac{4n^2}{(M-1)^2}} \right) / I_0(\beta)$$

with

$$-\frac{M-1}{2} \leq n \leq \frac{M-1}{2},$$

where  $I_0$  is the modified zeroth-order Bessel function.

The Kaiser was named for Jim Kaiser, who discovered a simple approximation to the DPSS window based on Bessel functions. The Kaiser window is a very good approximation to the Digital Prolate Spheroidal Sequence, or Slepian window, which is the transform which maximizes the energy in the main lobe of the window relative to total energy.

The Kaiser can approximate other windows by varying the beta parameter. (Some literature uses alpha = beta/pi.) [R282]

beta	Window shape
0	Rectangular
5	Similar to a Hamming
6	Similar to a Hann
8.6	Similar to a Blackman

A beta value of 14 is probably a good starting point. Note that as beta gets large, the window narrows, and so the number of samples needs to be large enough to sample the increasingly narrow spike, otherwise NaNs will be returned.

Most references to the Kaiser window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

[R279], [R280], [R281], [R282]

**Examples**

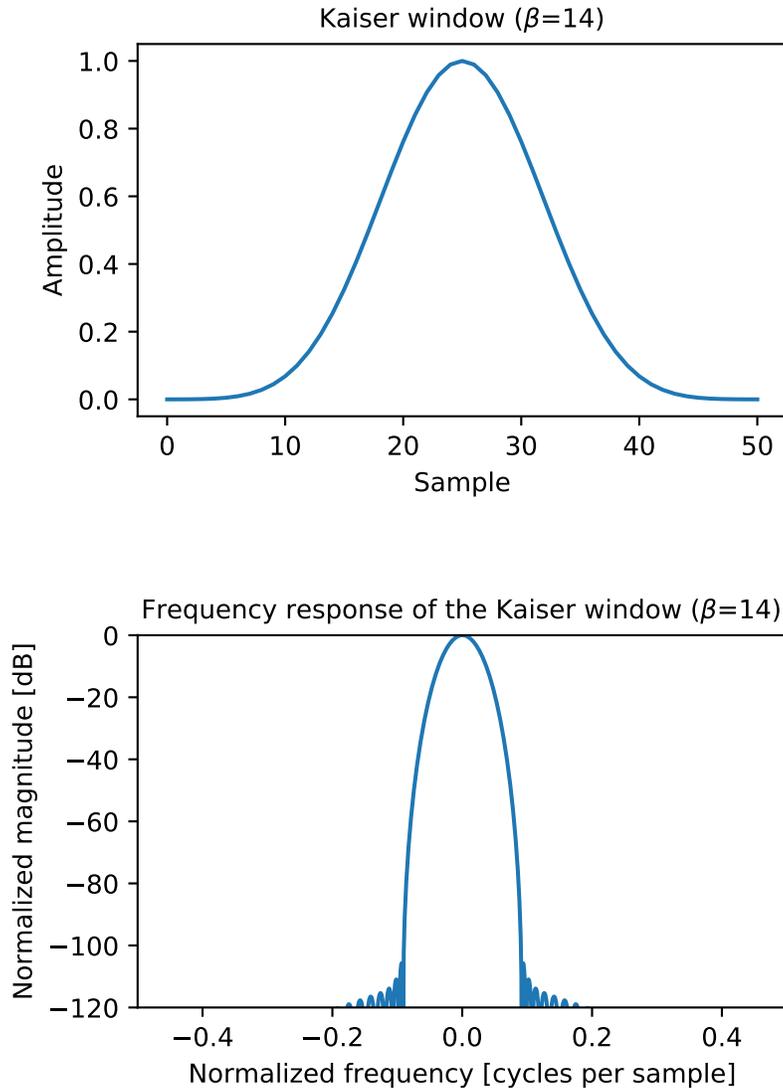

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.kaiser(51, beta=14)
>>> plt.plot(window)
>>> plt.title(r"Kaiser window (\beta=14)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
```

```
>>> plt.title(r"Frequency response of the Kaiser window ( $\beta=14$ )")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.nuttall` ( $M$ ,  $sym=True$ )

Return a minimum 4-term Blackman-Harris window according to Nuttall.

This variation is called “Nuttall4c” by Heinzel. [R292]

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design.

When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

## References

[R291], [R292]

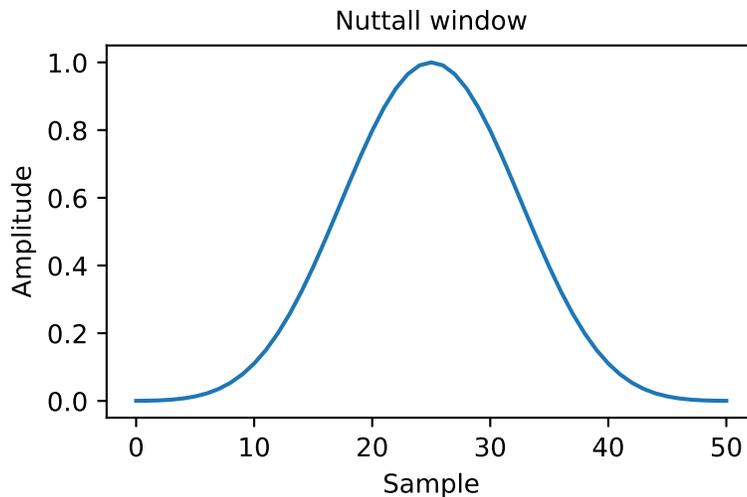

## Examples

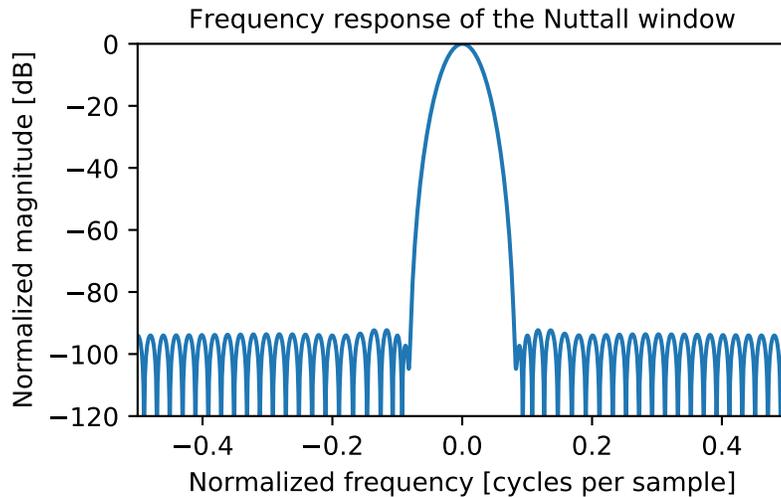

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.nuttall(51)
>>> plt.plot(window)
>>> plt.title("Nuttall window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Nuttall window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.parzen` ( $M$ ,  $sym=True$ )

Return a Parzen window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### References

[R293]

### Examples

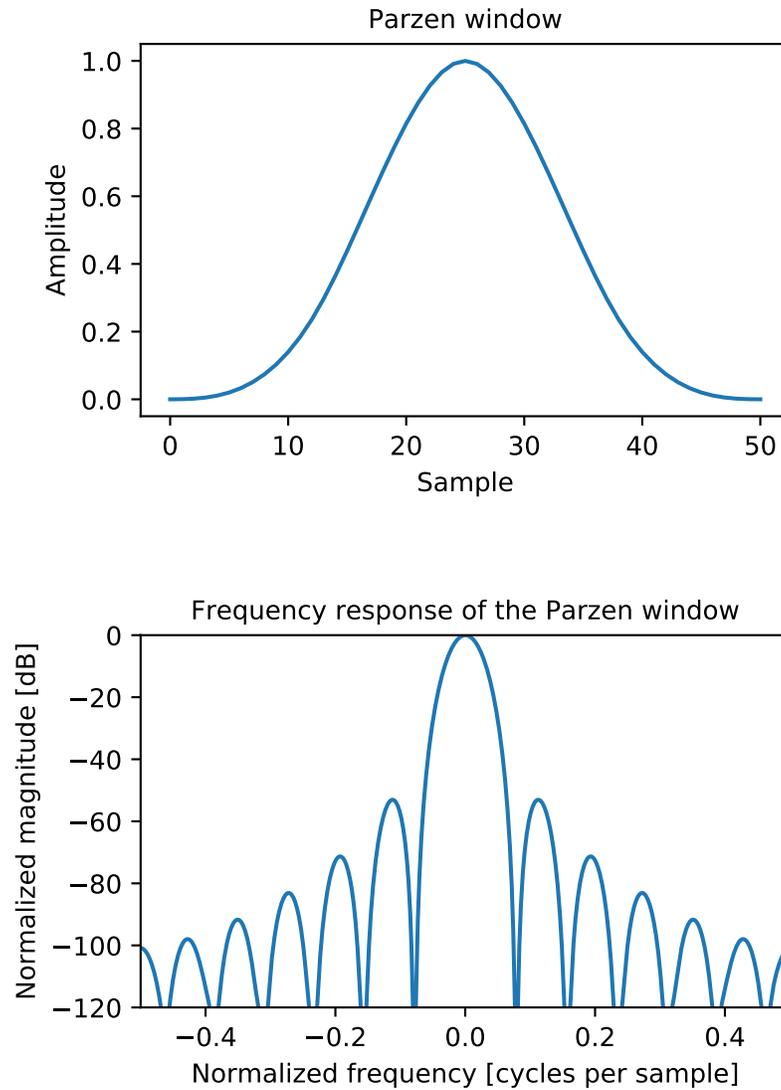

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.parzen(51)
>>> plt.plot(window)
>>> plt.title("Parzen window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Parzen window")
```

```
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.slepian` ( $M$ ,  $width$ ,  $sym=True$ )

Return a digital Slepian (DPSS) window.

Used to maximize the energy concentration in the main lobe. Also called the digital prolate spheroidal sequence (DPSS).

**Parameters**    **M** : int

Number of points in the output window. If zero or less, an empty array is returned.

**width** : float

Bandwidth

**sym** : bool, optional

When True (default), generates a symmetric window, for use in filter design.

When False, generates a periodic window, for use in spectral analysis.

**Returns**        **w** : ndarray

The window, with the maximum value always normalized to 1

### References

[R298], [R299]

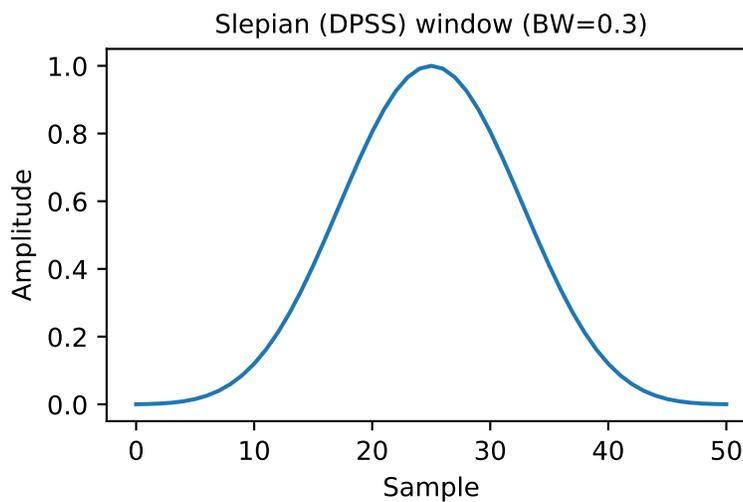

### Examples

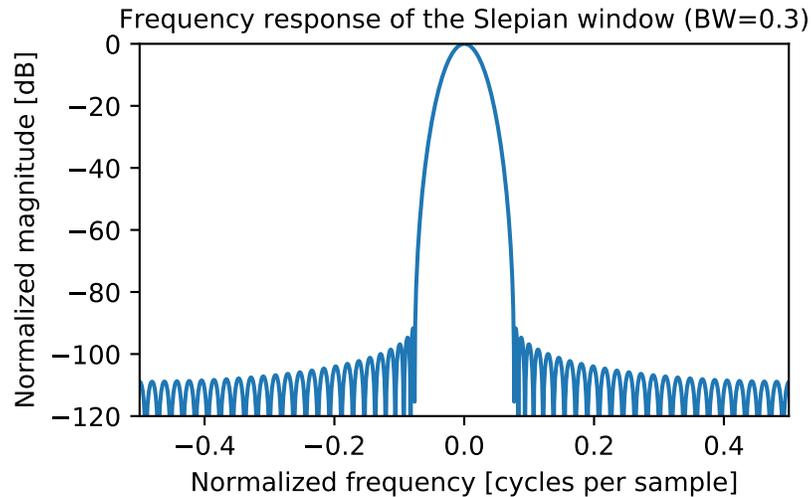

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.slepian(51, width=0.3)
>>> plt.plot(window)
>>> plt.title("Slepian (DPSS) window (BW=0.3)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Slepian window (BW=0.3)")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.triang` ( $M$ ,  $sym=True$ )

Return a triangular window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

**See also:**

**bartlett** A triangular window that touches zero

**Examples**

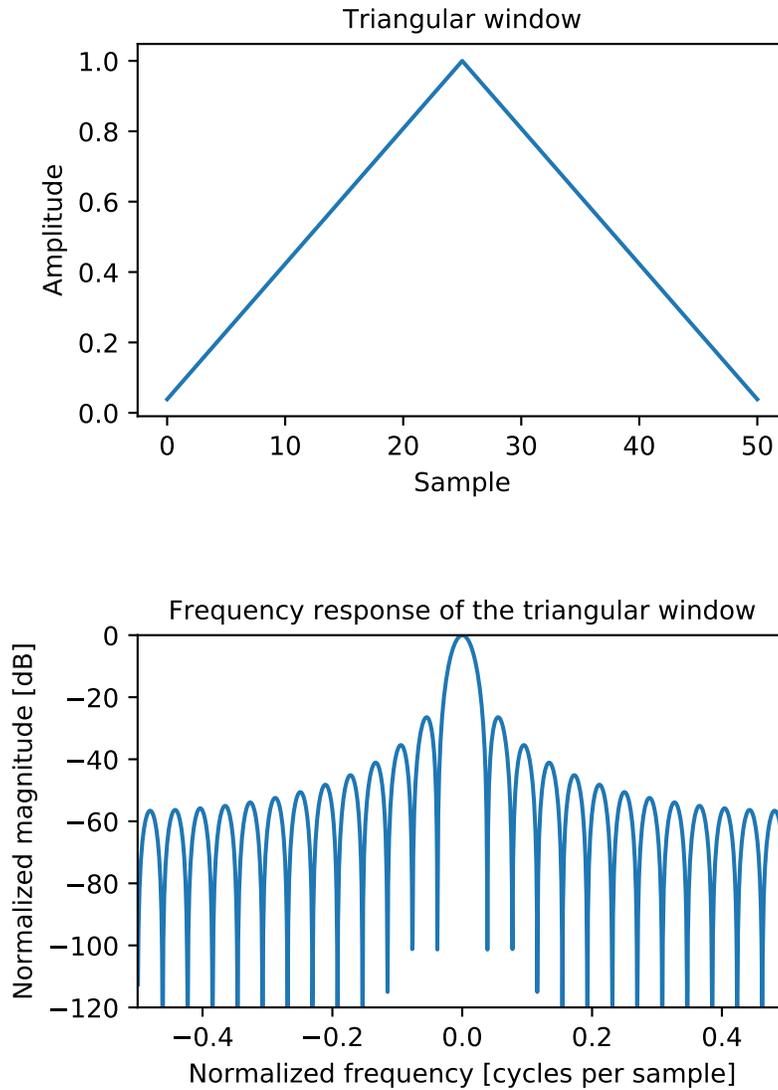

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.triang(51)
>>> plt.plot(window)
>>> plt.title("Triangular window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the triangular window")
```

```
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.tukey` ( $M$ ,  $\alpha=0.5$ ,  $\text{sym}=\text{True}$ )

Return a Tukey window, also known as a tapered cosine window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

**alpha** : float, optional

Shape parameter of the Tukey window, representing the fraction of the window inside the cosine tapered region. If zero, the Tukey window is equivalent to a rectangular window. If one, the Tukey window is equivalent to a Hann window.

**sym** : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns** `w` : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and `sym` is True).

### References

[R303], [R304]

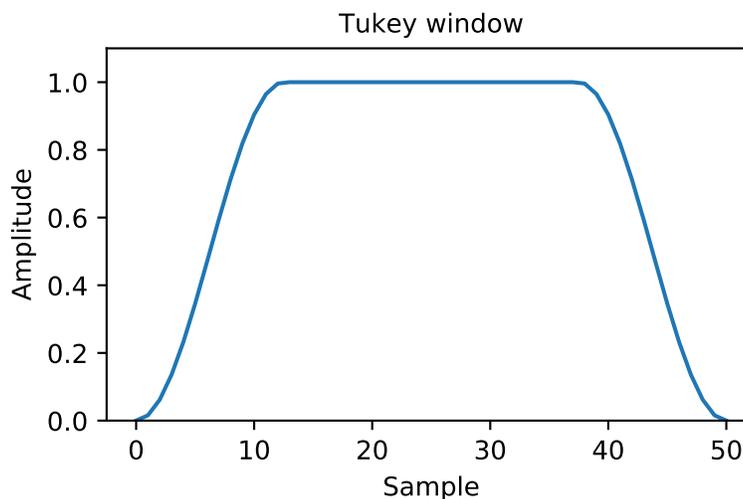

### Examples

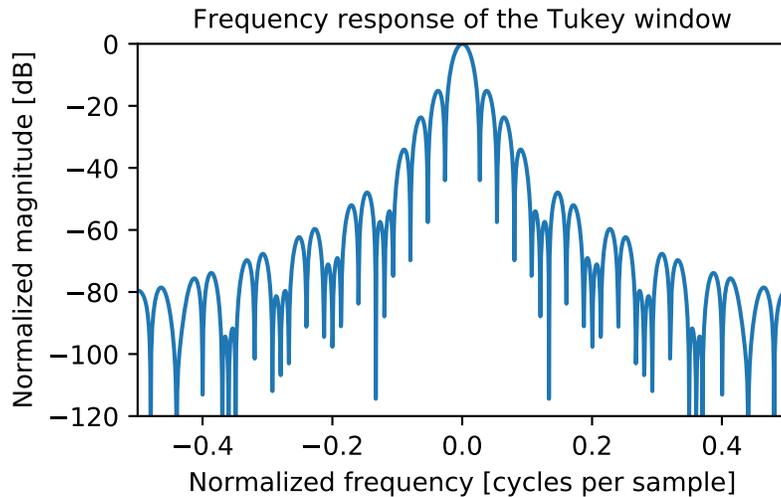

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```
>>> window = signal.tukey(51)
>>> plt.plot(window)
>>> plt.title("Tukey window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
>>> plt.ylim([0, 1.1])
```

```
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Tukey window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

## 5.20.11 Wavelets

<code>cascade(hk[, J])</code>	Return (x, phi, psi) at dyadic points $K/2^{**J}$ from filter coefficients.
<code>daub(p)</code>	The coefficients for the FIR low-pass filter producing Daubechies wavelets.
<code>morlet(M[, w, s, complete])</code>	Complex Morlet wavelet.
<code>qmf(hk)</code>	Return high-pass qmf filter from low-pass
<code>ricker(points, a)</code>	Return a Ricker wavelet, also known as the “Mexican hat wavelet”.
<code>cwt(data, wavelet, widths)</code>	Continuous wavelet transform.

`scipy.signal.cascade(hk, J=7)`

Return (x, phi, psi) at dyadic points  $K/2^{**J}$  from filter coefficients.

**Parameters** **hk** : array\_like

Coefficients of low-pass filter.

**J** : int, optional

Values will be computed at grid points  $K/2^{**J}$ . Default is 7.

**Returns**

**x** : ndarray

The dyadic points  $K/2^{**J}$  for  $K=0 \dots N * (2^{**J}) - 1$  where  $\text{len}(hk) = \text{len}(gk) = N+1$ .

**phi** : ndarray

The scaling function  $\text{phi}(x)$  at  $x$ :  $\text{phi}(x) = \text{sum}(hk * \text{phi}(2x-k))$ , where  $k$  is from 0 to  $N$ .

**psi** : ndarray, optional

The wavelet function  $\text{psi}(x)$  at  $x$ :  $\text{psi}(x) = \text{sum}(gk * \text{phi}(2x-k))$ , where  $k$  is from 0 to  $N$ . *psi* is only returned if *gk* is not None.

### Notes

The algorithm uses the vector cascade algorithm described by Strang and Nguyen in “Wavelets and Filter Banks”. It builds a dictionary of values and slices for quick reuse. Then inserts vectors into final vector at

where  $A = 2/\sqrt{3a}\pi^{1/4}$ .

**Parameters** **points** : int  
Number of points in *vector*. Will be centered around 0.

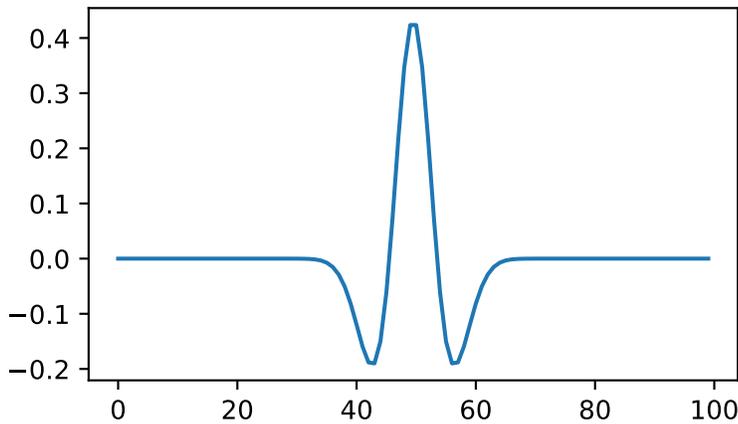

**a** : scalar  
Width parameter of the wavelet.

**Returns** **vector** : (N,) ndarray  
Array of length *points* in shape of ricker curve.

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> points = 100
>>> a = 4.0
>>> vec2 = signal.ricker(points, a)
>>> print(len(vec2))
100
>>> plt.plot(vec2)
>>> plt.show()
```

`scipy.signal.cwt` (*data*, *wavelet*, *widths*)

Continuous wavelet transform.

Performs a continuous wavelet transform on *data*, using the *wavelet* function. A CWT performs a convolution with *data* using the *wavelet* function, which is characterized by a width parameter and length parameter.

**Parameters** **data** : (N,) ndarray  
data on which to perform the transform.

**wavelet** : function  
Wavelet function, which should take 2 arguments. The first argument is the number of points that the returned vector will have (`len(wavelet(length,width)) == length`). The second is a width parameter, defining the size of the wavelet (e.g. standard deviation of a gaussian). See *ricker*, which satisfies these requirements.

**widths** : (M,) sequence  
Widths to use for transform.

**Returns** **cwt**: (M, N) ndarray

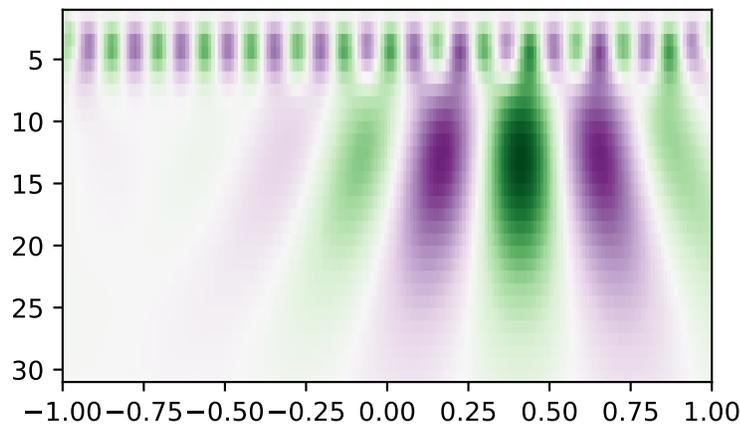

Will have shape of `(len(widths), len(data))`.

### Notes

```
length = min(10 * width[ii], len(data))
cwt[ii, :] = signal.convolve(data, wavelet(length,
                                         width[ii]), mode='same')
```

### Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 200, endpoint=False)
>>> sig = np.cos(2 * np.pi * 7 * t) + signal.gausspulse(t - 0.4, fc=2)
>>> widths = np.arange(1, 31)
>>> cwtmatr = signal.cwt(sig, signal.ricker, widths)
>>> plt.imshow(cwtmatr, extent=[-1, 1, 31, 1], cmap='PRGn', aspect='auto',
...           vmax=abs(cwtmatr).max(), vmin=-abs(cwtmatr).max())
>>> plt.show()
```

## 5.20.12 Peak finding

<code>find_peaks_cwt(vector, widths[, wavelet, ...])</code>	Attempt to find the peaks in a 1-D array.
<code>argrelnmin(data[, axis, order, mode])</code>	Calculate the relative minima of <i>data</i> .
<code>argrelnmax(data[, axis, order, mode])</code>	Calculate the relative maxima of <i>data</i> .
<code>argrelnrema(data, comparator[, axis, ...])</code>	Calculate the relative extrema of <i>data</i> .

`scipy.signal.find_peaks_cwt` (*vector*, *widths*, *wavelet=None*, *max\_distances=None*, *gap\_thresh=None*, *min\_length=None*, *min\_snr=1*, *noise\_perc=10*)  
 Attempt to find the peaks in a 1-D array.

The general approach is to smooth *vector* by convolving it with *wavelet(width)* for each width in *widths*. Relative maxima which appear at enough length scales, and with sufficiently high SNR, are accepted.

**Parameters** *vector* : ndarray

1-D array in which to find the peaks.

**widths** : sequence

1-D array of widths to use for calculating the CWT matrix. In general, this range should cover the expected width of peaks of interest.

**wavelet** : callable, optional

Should take two parameters and return a 1-D array to convolve with *vector*. The first parameter determines the number of points of the returned wavelet array, the second parameter is the scale (*width*) of the wavelet. Should be normalized and symmetric. Default is the ricker wavelet.

**max\_distances** : ndarray, optional

At each row, a ridge line is only connected if the relative max at row[n] is within `max_distances[n]` from the relative max at row[n+1]. Default value is `widths/4`.

**gap\_thresh** : float, optional

If a relative maximum is not found within *max\_distances*, there will be a gap. A ridge line is discontinued if there are more than *gap\_thresh* points without connecting a new relative maximum. Default is the first value of the widths array i.e. `widths[0]`.

**min\_length** : int, optional

Minimum length a ridge line needs to be acceptable. Default is `cwt.shape[0] / 4`, ie 1/4-th the number of widths.

**min\_snr** : float, optional

Minimum SNR ratio. Default 1. The signal is the value of the cwt matrix at the shortest length scale (`cwt[0, loc]`), the noise is the *noise\_perc*'th percentile of datapoints contained within a window of *window\_size* around `cwt[0, loc]`.

**noise\_perc** : float, optional

When calculating the noise floor, percentile of data points examined below which to consider noise. Calculated using *stats.scoreatpercentile*. Default is 10.

**Returns**

**peaks\_indices** : ndarray

Indices of the locations in the *vector* where peaks were found. The list is sorted.

**See also:**

*cwt*

**Notes**

This approach was designed for finding sharp peaks among noisy data, however with proper parameter selection it should function well for different peak shapes.

*The algorithm is as follows:*

1. Perform a continuous wavelet transform on *vector*, for the supplied *widths*. This is a convolution of *vector* with *wavelet(width)* for each width in *widths*. See *cwt*
2. Identify "ridge lines" in the cwt matrix. These are relative maxima at each row, connected across adjacent rows. See *identify\_ridge\_lines*
3. Filter the *ridge\_lines* using *filter\_ridge\_lines*.

New in version 0.11.0.

**References**

[R253]

**Examples**

```
>>> from scipy import signal
>>> xs = np.arange(0, np.pi, 0.05)
>>> data = np.sin(xs)
>>> peakind = signal.find_peaks_cwt(data, np.arange(1,10))
>>> peakind, xs[peakind], data[peakind]
([32], array([ 1.6]), array([ 0.9995736]))
```

`scipy.signal.argrelmin` (*data*, *axis=0*, *order=1*, *mode='clip'*)

Calculate the relative minima of *data*.

**Parameters**

- data** : ndarray  
Array in which to find the relative minima.
- axis** : int, optional  
Axis over which to select from *data*. Default is 0.
- order** : int, optional  
How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.
- mode** : str, optional  
How the edges of the vector are treated. Available options are 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default 'clip'. See `numpy.take`.

**Returns**

- extrema** : tuple of ndarrays  
Indices of the minima in arrays of integers. `extrema[k]` is the array of indices of axis *k* of *data*. Note that the return value is a tuple even when *data* is one-dimensional.

**See also:**

`argrelextrema`, `argrelmax`

**Notes**

This function uses `argrelextrema` with `np.less` as comparator.

New in version 0.11.0.

**Examples**

```
>>> from scipy.signal import argrelmin
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmin(x)
(array([1, 5]),)
>>> y = np.array([[1, 2, 1, 2],
...              [2, 2, 0, 0],
...              [5, 3, 4, 4]])
...
>>> argrelmin(y, axis=1)
(array([0, 2]), array([2, 1]))
```

`scipy.signal.argrelmax` (*data*, *axis=0*, *order=1*, *mode='clip'*)

Calculate the relative maxima of *data*.

**Parameters**

- data** : ndarray  
Array in which to find the relative maxima.
- axis** : int, optional  
Axis over which to select from *data*. Default is 0.
- order** : int, optional

How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.

**mode** : str, optional  
 How the edges of the vector are treated. Available options are ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element). Default ‘clip’. See `numpy.take`.

**Returns** **extrema** : tuple of ndarrays  
 Indices of the maxima in arrays of integers. `extrema[k]` is the array of indices of axis *k* of *data*. Note that the return value is a tuple even when *data* is one-dimensional.

**See also:**

`argrelextrema`, `argrelmin`

**Notes**

This function uses `argrelextrema` with `np.greater` as comparator.

New in version 0.11.0.

**Examples**

```
>>> from scipy.signal import argrelmax
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmax(x)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
...               [2, 2, 0, 0],
...               [5, 3, 4, 4]])
...
>>> argrelmax(y, axis=1)
(array([0]), array([1]))
```

`scipy.signal.argrelextrema` (*data*, *comparator*, *axis=0*, *order=1*, *mode='clip'*)

Calculate the relative extrema of *data*.

**Parameters** **data** : ndarray  
 Array in which to find the relative extrema.

**comparator** : callable  
 Function to use to compare two data points. Should take two arrays as arguments.

**axis** : int, optional  
 Axis over which to select from *data*. Default is 0.

**order** : int, optional  
 How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.

**mode** : str, optional  
 How the edges of the vector are treated. ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element). Default is ‘clip’.

**Returns** **extrema** : tuple of ndarrays  
 See `numpy.take`.  
 Indices of the maxima in arrays of integers. `extrema[k]` is the array of indices of axis *k* of *data*. Note that the return value is a tuple even when *data* is one-dimensional.

**See also:**

`argrelmin`, `argrelmax`

### Notes

New in version 0.11.0.

### Examples

```

>>> from scipy.signal import argrextrema
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrextrema(x, np.greater)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
...               [2, 2, 0, 0],
...               [5, 3, 4, 4]])
...
>>> argrextrema(y, np.less, axis=1)
(array([0, 2]), array([2, 1]))

```

## 5.20.13 Spectral Analysis

<code>periodogram(x[, fs, window, nfft, detrend, ...])</code>	Estimate power spectral density using a periodogram.
<code>welch(x[, fs, window, nperseg, noverlap, ...])</code>	Estimate power spectral density using Welch's method.
<code>csd(x, y[, fs, window, nperseg, noverlap, ...])</code>	Estimate the cross power spectral density, $P_{xy}$ , using Welch's method.
<code>coherence(x, y[, fs, window, nperseg, ...])</code>	Estimate the magnitude squared coherence estimate, $C_{xy}$ , of discrete-time signals $X$ and $Y$ using Welch's method.
<code>spectrogram(x[, fs, window, nperseg, ...])</code>	Compute a spectrogram with consecutive Fourier transforms.
<code>lombscargle(x, y, freqs)</code>	Computes the Lomb-Scargle periodogram.
<code>vectorstrength(events, period)</code>	Determine the vector strength of the events corresponding to the given period.
<code>stft(x[, fs, window, nperseg, noverlap, ...])</code>	Compute the Short Time Fourier Transform (STFT).
<code>istft(Zxx[, fs, window, nperseg, noverlap, ...])</code>	Perform the inverse Short Time Fourier transform (iSTFT).
<code>check_COLA(window, nperseg, noverlap[, tol])</code>	Check whether the Constant OverLap Add (COLA) constraint is met

`scipy.signal.periodogram(x, fs=1.0, window='boxcar', nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)`  
 Estimate power spectral density using a periodogram.

**Parameters** `x` : array\_like

Time series of measurement values

`fs` : float, optional

Sampling frequency of the  $x$  time series. Defaults to 1.0.

`window` : str or tuple or array\_like, optional

Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array\_like it will be used directly as the window and its length must be `nperseg`. Defaults to 'boxcar'.

`nfft` : int, optional

Length of the FFT used. If `None` the length of  $x$  will be used.

`detrend` : str or function or `False`, optional

Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the *detrend* function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is *False*, no detrending is done. Defaults to 'constant'.

**return\_onesided** : bool, optional

If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.

**scaling** : { 'density', 'spectrum' }, optional

Selects between computing the power spectral density ('density') where *Pxx* has units of  $V^{**2}/Hz$  and computing the power spectrum ('spectrum') where *Pxx* has units of  $V^{**2}$ , if *x* is measured in V and *fs* is measured in Hz. Defaults to 'density'

**axis** : int, optional

Axis along which the periodogram is computed; the default is over the last axis (i.e. *axis=-1*).

**Returns**

**f** : ndarray

Array of sample frequencies.

**Pxx** : ndarray

Power spectral density or power spectrum of *x*.

**See also:**

**welch** Estimate power spectral density using Welch's method

**lombscargle** Lomb-Scargle periodogram for unevenly sampled data

**Notes**

New in version 0.12.0.

**Examples**

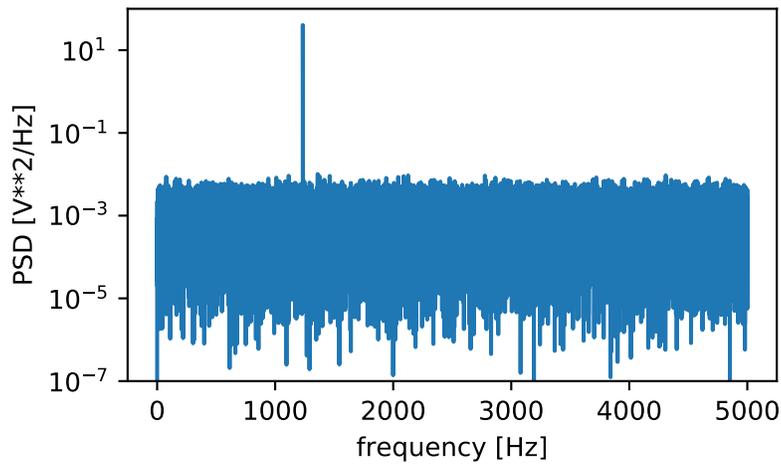

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)
```

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001  $V^{**2}/Hz$  of white noise sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
```

Compute and plot the power spectral density.

```
>>> f, Pxx_den = signal.periodogram(x, fs)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([1e-7, 1e2])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

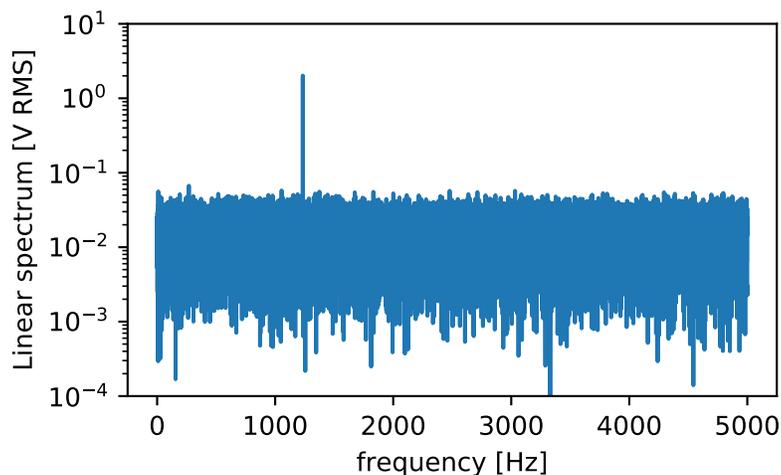

If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```
>>> np.mean(Pxx_den[25000:])
0.00099728892368242854
```

Now compute and plot the power spectrum.

```
>>> f, Pxx_spec = signal.periodogram(x, fs, 'flattop', scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.ylim([1e-4, 1e1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

The peak height in the power spectrum is an estimate of the RMS amplitude.

```
>>> np.sqrt(Pxx_spec.max())
2.0077340678640727
```

`scipy.signal.welch(x, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)`  
 Estimate power spectral density using Welch's method.

Welch's method [R306] computes an estimate of the power spectral density by dividing the data into overlapping segments, computing a modified periodogram for each segment and averaging the periodograms.

**Parameters**

- x** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the *x* time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. If *window* is a string or tuple, it is passed to *get\_window* to generate the window values, which are DFT-even by default. See *get\_window* for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Hann window.
- nperseg** : int, optional  
Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array\_like, is set to the length of the window.
- nooverlap** : int, optional  
Number of points to overlap between segments. If None, *nooverlap* = *nperseg* // 2. Defaults to None.
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is *nperseg*. Defaults to None.
- detrend** : str or function or False, optional  
Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the *detrend* function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is False, no detrending is done. Defaults to 'constant'.
- return\_onesided** : bool, optional  
If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.
- scaling** : { 'density', 'spectrum' }, optional  
Selects between computing the power spectral density ('density') where *Pxx* has units of V\*\*2/Hz and computing the power spectrum ('spectrum') where *Pxx* has units of V\*\*2, if *x* is measured in V and *fs* is measured in Hz. Defaults to 'density'
- axis** : int, optional  
Axis along which the periodogram is computed; the default is over the last axis (i.e. *axis*=-1).

**Returns**

- f** : ndarray  
Array of sample frequencies.
- Pxx** : ndarray  
Power spectral density or power spectrum of *x*.

See also:

**periodogram**  
 Simple, optionally modified periodogram

**lombscargle**

Lomb-Scargle periodogram for unevenly sampled data

**Notes**

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

If *noverlap* is 0, this method is equivalent to Bartlett's method [R307].

New in version 0.12.0.

**Examples**

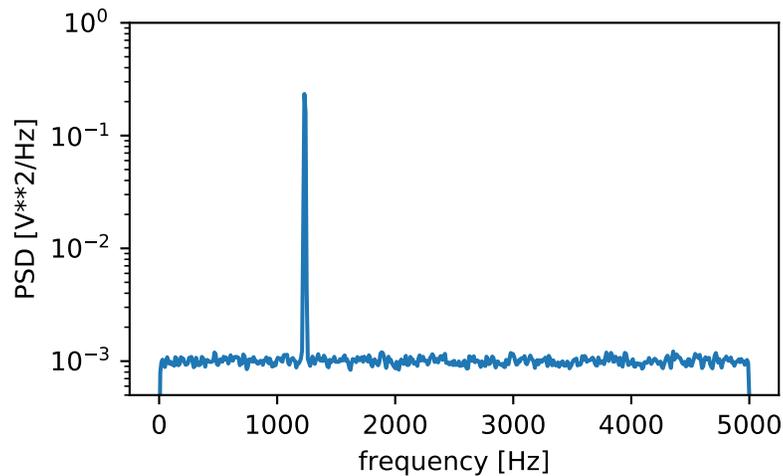

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)
```

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V\*\*2/Hz of white noise sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
```

Compute and plot the power spectral density.

```
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

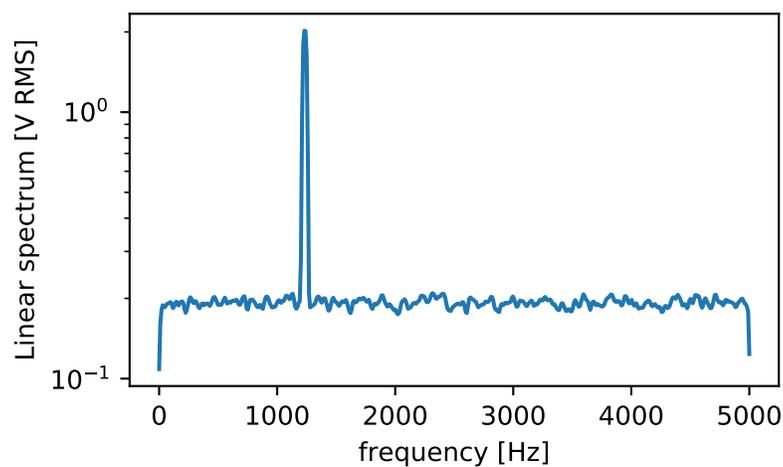

If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```
>>> np.mean(Pxx_den[256:])
0.0009924865443739191
```

Now compute and plot the power spectrum.

```
>>> f, Pxx_spec = signal.welch(x, fs, 'flattop', 1024, scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

The peak height in the power spectrum is an estimate of the RMS amplitude.

```
>>> np.sqrt(Pxx_spec.max())
2.0077340678640727
```

`scipy.signal.csd(x, y, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)`

Estimate the cross power spectral density,  $P_{xy}$ , using Welch's method.

**Parameters**

- x** : array\_like  
Time series of measurement values
- y** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the  $x$  and  $y$  time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. If *window* is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be `nperseg`. Defaults to a Hann window.
- nperseg** : int, optional  
Length of each segment. Defaults to `None`, but if *window* is str or tuple, is set to 256, and if *window* is array\_like, is set to the length of the window.
- noverlap** : int, optional  
Number of points to overlap between segments. If `None`, `noverlap = nperseg // 2`. Defaults to `None`.
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If `None`, the FFT length is `nperseg`. Defaults to `None`.
- detrend** : str or function or `False`, optional  
Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the *detrend* function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is `False`, no detrending is done. Defaults to 'constant'.
- return\_onesided** : bool, optional  
If `True`, return a one-sided spectrum for real data. If `False` return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.
- scaling** : { 'density', 'spectrum' }, optional  
Selects between computing the cross spectral density ('density') where  $P_{xy}$  has units of  $V^{**2}/Hz$  and computing the cross spectrum ('spectrum') where  $P_{xy}$  has units of  $V^{**2}$ , if  $x$  and  $y$  are measured in  $V$  and  $fs$  is measured in  $Hz$ . Defaults to 'density'
- axis** : int, optional  
Axis along which the CSD is computed for both inputs; the default is over the last axis (i.e. `axis=-1`).

**Returns**

- f** : ndarray  
Array of sample frequencies.
- Pxy** : ndarray  
Cross spectral density or cross power spectrum of  $x,y$ .

See also:

**periodogram**

Simple, optionally modified periodogram

**lombscargle**

Lomb-Scargle periodogram for unevenly sampled data

**welch** Power spectral density by Welch's method. [Equivalent to `csd(x,x)`]  
**coherence** Magnitude squared coherence by Welch's method.

### Notes

By convention, `Pxy` is computed with the conjugate FFT of `X` multiplied by the FFT of `Y`.

If the input series differ in length, the shorter series will be zero-padded to match.

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

New in version 0.16.0.

### Examples

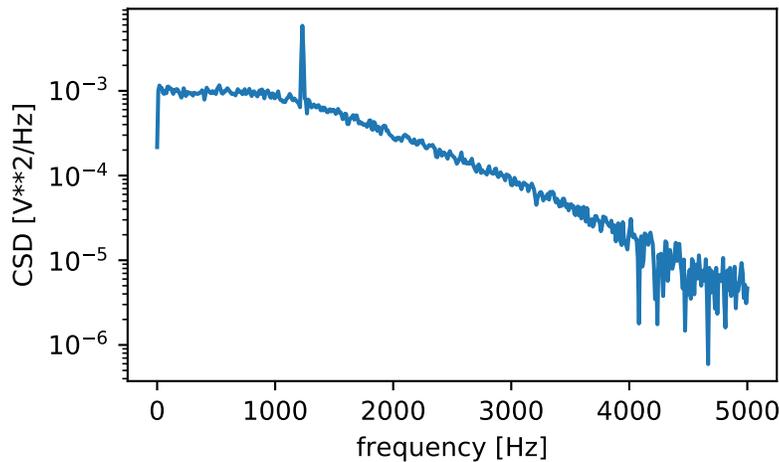

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate two test signals with some common features.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += np.random.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)
```

Compute and plot the magnitude of the cross spectral density.

```
>>> f, Pxy = signal.csd(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, np.abs(Pxy))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('CSD [V**2/Hz]')
>>> plt.show()
```

`scipy.signal.coherence` (*x*, *y*, *fs*=1.0, *window*='hann', *nperseg*=None, *noverlap*=None, *nfft*=None, *detrend*='constant', *axis*=-1)

Estimate the magnitude squared coherence estimate,  $C_{xy}$ , of discrete-time signals *X* and *Y* using Welch's method.

$C_{xy} = \text{abs}(P_{xy}) ** 2 / (P_{xx} * P_{yy})$ , where  $P_{xx}$  and  $P_{yy}$  are power spectral density estimates of *X* and *Y*, and  $P_{xy}$  is the cross spectral density estimate of *X* and *Y*.

**Parameters**

- x** : array\_like  
Time series of measurement values
- y** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the *x* and *y* time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. If *window* is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Hann window.
- nperseg** : int, optional  
Length of each segment. Defaults to None, but if *window* is str or tuple, is set to 256, and if *window* is array\_like, is set to the length of the window.
- noverlap**: int, optional  
Number of points to overlap between segments. If None, *noverlap* = *nperseg* // 2. Defaults to None.
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is *nperseg*. Defaults to None.
- detrend** : str or function or False, optional  
Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the *detrend* function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is False, no detrending is done. Defaults to 'constant'.
- axis** : int, optional

**Returns**

<b>f</b> : ndarray	Axis along which the coherence is computed for both inputs; the default is over the last axis (i.e. <code>axis=-1</code> ).
<b>Cxy</b> : ndarray	Array of sample frequencies. Magnitude squared coherence of x and y.

**Examples**

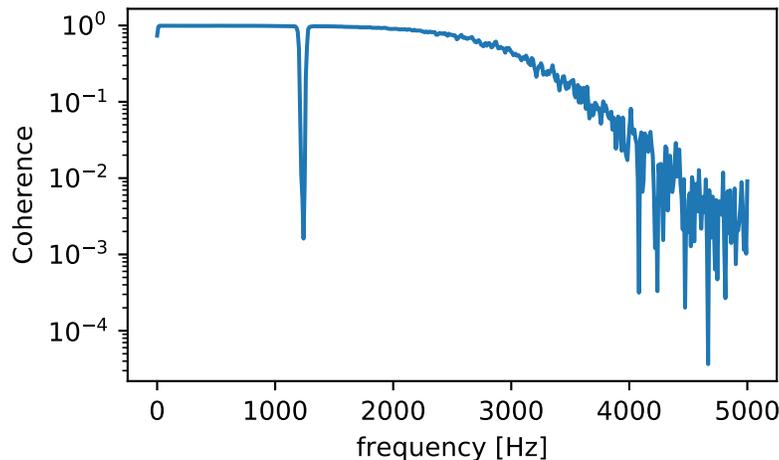

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate two test signals with some common features.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += np.random.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)
```

Compute and plot the coherence.

```
>>> f, Cxy = signal.coherence(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, Cxy)
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Coherence')
>>> plt.show()
```

```
scipy.signal.spectrogram(x, fs=1.0, window=('tukey', 0.25), nperseg=None, noverlap=None,
                        nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, mode='psd')
```

Compute a spectrogram with consecutive Fourier transforms.

Spectrograms can be used as a way of visualizing the change of a nonstationary signal's frequency content over time.

**Parameters**

- x** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the *x* time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. If *window* is a string or tuple, it is passed to *get\_window* to generate the window values, which are DFT-even by default. See *get\_window* for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Tukey window with shape parameter of 0.25.
- nperseg** : int, optional  
Length of each segment. Defaults to None, but if *window* is str or tuple, is set to 256, and if *window* is array\_like, is set to the length of the window.
- noverlap** : int, optional  
Number of points to overlap between segments. If None, *noverlap* = *nperseg* // 8. Defaults to None.
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is *nperseg*. Defaults to None.
- detrend** : str or function or False, optional  
Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the *detrend* function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is False, no detrending is done. Defaults to 'constant'.
- return\_onesided** : bool, optional  
If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.

**scaling** : { 'density', 'spectrum' }, optional  
 Selects between computing the power spectral density ('density') where  $S_{xx}$  has units of  $V^{**2}/\text{Hz}$  and computing the power spectrum ('spectrum') where  $S_{xx}$  has units of  $V^{**2}$ , if  $x$  is measured in  $V$  and  $fs$  is measured in  $\text{Hz}$ . Defaults to 'density'.

**axis** : int, optional  
 Axis along which the spectrogram is computed; the default is over the last axis (i.e. `axis=-1`).

**mode** : str, optional  
 Defines what kind of return values are expected. Options are ['psd', 'complex', 'magnitude', 'angle', 'phase']. 'complex' is equivalent to the output of `stft` with no padding or boundary extension. 'magnitude' returns the absolute magnitude of the STFT. 'angle' and 'phase' return the complex angle of the STFT, with and without unwrapping, respectively.

**Returns**

**f** : ndarray  
 Array of sample frequencies.

**t** : ndarray  
 Array of segment times.

**Sxx** : ndarray  
 Spectrogram of  $x$ . By default, the last axis of  $S_{xx}$  corresponds to the segment times.

**See also:**

**periodogram**

Simple, optionally modified periodogram

**lombscargle**

Lomb-Scargle periodogram for unevenly sampled data

**welch**

Power spectral density by Welch's method.

**csd**

Cross spectral density by Welch's method.

**Notes**

An appropriate amount of overlap will depend on the choice of window and on your requirements. In contrast to `welch`'s method, where the entire data stream is averaged over, one may wish to use a smaller overlap (or perhaps none at all) when computing a spectrogram, to maintain some statistical independence between individual segments. It is for this reason that the default window is a Tukey window with 1/8th of a window's length overlap at each end.

New in version 0.16.0.

**References**

[R300]

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
```

```

>>> mod = 500*np.cos(2*np.pi*0.25*time)
>>> carrier = amp * np.sin(2*np.pi*3e3*time + mod)
>>> noise = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise

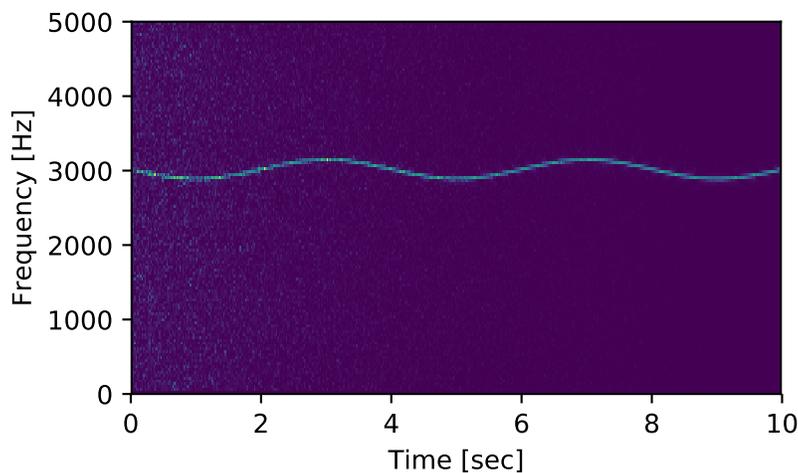

```

Compute and plot the spectrogram.

```

>>> f, t, Sxx = signal.spectrogram(x, fs)
>>> plt.pcolormesh(t, f, Sxx)
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()

```

`scipy.signal.lombscargle(x, y, freqs)`

Computes the Lomb-Scargle periodogram.

The Lomb-Scargle periodogram was developed by Lomb [R283] and further extended by Scargle [R284] to find, and test the significance of weak periodic signals with uneven temporal sampling.

When *normalize* is False (default) the computed periodogram is unnormalized, it takes the value  $(A^{**2}) * N/4$  for a harmonic signal with amplitude A for sufficiently large N.

When *normalize* is True the computed periodogram is normalized by the residuals of the data around a constant reference model (at zero).

Input arrays should be one-dimensional and will be cast to float64.

**Parameters**

- x** : array\_like  
Sample times.
- y** : array\_like  
Measurement values.
- freqs** : array\_like  
Angular frequencies for output periodogram.
- precenter** : bool, optional  
Pre-center amplitudes by subtracting the mean.
- normalize** : bool, optional  
Compute normalized periodogram.

**Returns**

- pgram** : array\_like

**Raises** **ValueError** Lomb-Scargle periodogram.  
If the input arrays  $x$  and  $y$  do not have the same shape.

**Notes**

This subroutine calculates the periodogram using a slightly modified algorithm due to Townsend [R285] which allows the periodogram to be calculated using only a single pass through the input arrays for each frequency.

The algorithm running time scales roughly as  $O(x * \text{freqs})$  or  $O(N^2)$  for a large number of samples and frequencies.

**References**

[R283], [R284], [R285]

**Examples**

```
>>> import scipy.signal
>>> import matplotlib.pyplot as plt
```

First define some input parameters for the signal:

```
>>> A = 2.
>>> w = 1.
>>> phi = 0.5 * np.pi
>>> nin = 1000
>>> nout = 100000
>>> frac_points = 0.9 # Fraction of points to select
```

Randomly select a fraction of an array with timesteps:

```
>>> r = np.random.rand(nin)
>>> x = np.linspace(0.01, 10*np.pi, nin)
>>> x = x[r >= frac_points]
```

Plot a sine wave for the selected times:

```
>>> y = A * np.sin(w*x+phi)
```

Define the array of frequencies for which to compute the periodogram:

```
>>> f = np.linspace(0.01, 10, nout)
```

Calculate Lomb-Scargle periodogram:

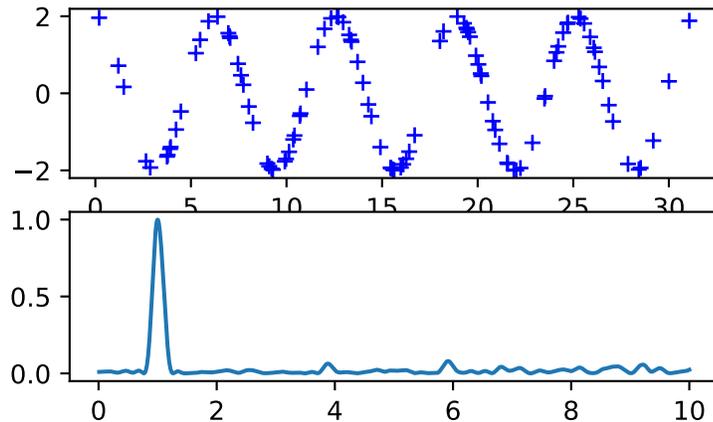

```
>>> import scipy.signal as signal
>>> pgram = signal.lombscargle(x, y, f, normalize=True)
```

Now make a plot of the input data:

```
>>> plt.subplot(2, 1, 1)
>>> plt.plot(x, y, 'b+')
```

Then plot the normalized periodogram:

```
>>> plt.subplot(2, 1, 2)
>>> plt.plot(f, pgram)
>>> plt.show()
```

`scipy.signal.vectorstrength(events, period)`

Determine the vector strength of the events corresponding to the given period.

The vector strength is a measure of phase synchrony, how well the timing of the events is synchronized to a single period of a periodic signal.

If multiple periods are used, calculate the vector strength of each. This is called the “resonating vector strength”.

**Parameters** **events** : 1D array\_like

An array of time points containing the timing of the events.

**period** : float or array\_like

The period of the signal that the events should synchronize to. The period is in the same units as *events*. It can also be an array of periods, in which case the outputs are arrays of the same length.

**Returns** **strength** : float or 1D array

The strength of the synchronization. 1.0 is perfect synchronization and 0.0 is no synchronization. If *period* is an array, this is also an array with each element containing the vector strength at the corresponding period.

**phase** : float or array

The phase that the events are most strongly synchronized to in radians. If *period* is an array, this is also an array with each element containing the phase for the corresponding period.

`scipy.signal.stft(x, fs=1.0, window='hann', nperseg=256, noverlap=None, nfft=None, detrend=False, return_onesided=True, boundary='zeros', padded=True, axis=-1)`  
Compute the Short Time Fourier Transform (STFT).

STFTs can be used as a way of quantifying the change of a nonstationary signal's frequency and phase content over time.

**Parameters**

- x** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the *x* time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. If *window* is a string or tuple, it is passed to *get\_window* to generate the window values, which are DFT-even by default. See *get\_window* for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Hann window.
- nperseg** : int, optional  
Length of each segment. Defaults to 256.
- noverlap** : int, optional  
Number of points to overlap between segments. If *None*, *noverlap* = *nperseg* // 2. Defaults to *None*. When specified, the COLA constraint must be met (see Notes below).
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is *nperseg*. Defaults to *None*.
- detrend** : str or function or *False*, optional  
Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the *detrend* function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is *False*, no detrending is done. Defaults to *False*.
- return\_onesided** : bool, optional  
If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned. Defaults to *True*.
- boundary** : str or *None*, optional  
Specifies whether the input signal is extended at both ends, and how to generate the new values, in order to center the first windowed segment on the first input point. This has the benefit of enabling reconstruction of the first input point when the employed window function starts at zero. Valid options are ['even', 'odd', 'constant', 'zeros', *None*]. Defaults to 'zeros', for zero padding extension. I.e. [1, 2, 3, 4] is extended to [0, 1, 2, 3, 4, 0] for *nperseg*=3.
- padded** : bool, optional  
Specifies whether the input signal is zero-padded at the end to make the signal fit exactly into an integer number of window segments, so that all of the signal is included in the output. Defaults to *True*. Padding occurs after boundary extension, if *boundary* is not *None*, and *padded* is *True*, as is the default.
- axis** : int, optional  
Axis along which the STFT is computed; the default is over the last axis (i.e. *axis*=-1).

**Returns**

- f** : ndarray  
Array of sample frequencies.
- t** : ndarray  
Array of segment times.
- Zxx** : ndarray

STFT of  $x$ . By default, the last axis of  $Z_{xx}$  corresponds to the segment times.

**See also:**

**istft** Inverse Short Time Fourier Transform  
**check\_COLA** Check whether the Constant OverLap Add (COLA) constraint is met  
**welch** Power spectral density by Welch's method.  
**spectrogram**  
 Spectrogram by Welch's method.  
**csd** Cross spectral density by Welch's method.  
**lombscargle**  
 Lomb-Scargle periodogram for unevenly sampled data

**Notes**

In order to enable inversion of an STFT via the inverse STFT in *istft*, the signal windowing must obey the constraint of “Constant OverLap Add” (COLA), and the input signal must have complete windowing coverage (i.e.  $(x.shape[axis] - nperseg) \% (nperseg - noverlap) == 0$ ). The *padded* argument may be used to accomplish this.

The COLA constraint ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction. Whether a choice of *window*, *nperseg*, and *noverlap* satisfy this constraint can be tested with *check\_COLA*.

New in version 0.19.0.

[R301], [R302]

**Examples**

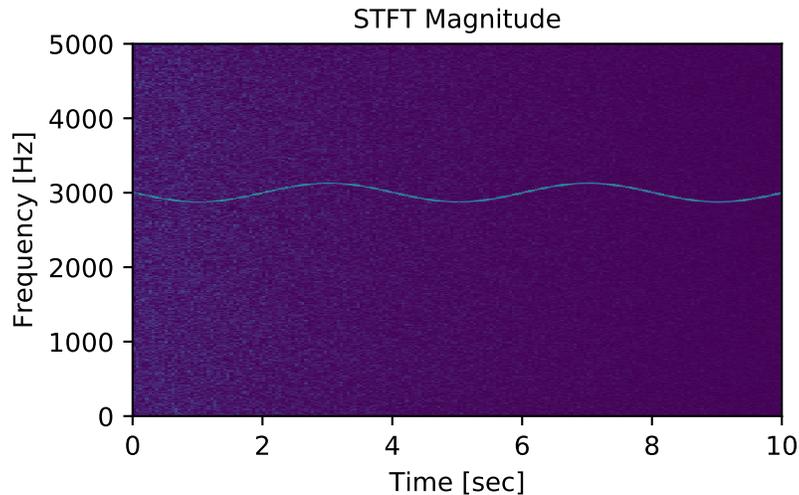

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500 * np.cos(2 * np.pi * 0.25 * time)
>>> carrier = amp * np.sin(2 * np.pi * 3e3 * time + mod)
>>> noise = np.random.normal(scale=np.sqrt(noise_power),
...                          size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

Compute and plot the STFT's magnitude.

```
>>> f, t, Zxx = signal.stft(x, fs, nperseg=1000)
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp)
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

`scipy.signal.istft` (*Zxx*, *fs=1.0*, *window='hann'*, *nperseg=None*, *noverlap=None*, *nfft=None*, *input\_onesided=True*, *boundary=True*, *time\_axis=-1*, *freq\_axis=-2*)  
 Perform the inverse Short Time Fourier transform (iSTFT).

**Parameters** *Zxx* : array\_like

STFT of the signal to be reconstructed. If a purely real array is passed, it will be cast to a complex data type.

*fs* : float, optional

Sampling frequency of the time series. Defaults to 1.0.

**window** : str or tuple or array\_like, optional

Desired window to use. If *window* is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Hann window. Must match the window used to generate the STFT for faithful inversion.

**nperseg** : int, optional

Number of data points corresponding to each STFT segment. This parameter must be specified if the number of data points per segment is odd, or if the STFT was padded via *nfft* > *nperseg*. If *None*, the value depends on the shape of *Zxx* and *input\_onesided*. If *input\_onesided* is *True*, *nperseg*=2\*(*Zxx*.shape[*freq\_axis*] - 1). Otherwise, *nperseg*=*Zxx*.shape[*freq\_axis*]. Defaults to *None*.

**noverlap** : int, optional

Number of points to overlap between segments. If *None*, half of the segment length. Defaults to *None*. When specified, the COLA constraint must be met (see Notes below), and should match the parameter used to generate the STFT. Defaults to *None*.

**nfft** : int, optional

Number of FFT points corresponding to each STFT segment. This parameter must be specified if the STFT was padded via *nfft* > *nperseg*. If *None*, the default values are the same as for *nperseg*, detailed above, with one exception: if *input\_onesided* is *True* and *nperseg*==2\**Zxx*.shape[*freq\_axis*] - 1, *nfft* also takes on that value. This case allows the proper inversion of an odd-length unpadded STFT using *nfft*=*None*. Defaults to *None*.

**input\_onesided** : bool, optional  
 If *True*, interpret the input array as one-sided FFTs, such as is returned by *stft* with `return_onesided=True` and `numpy.fft.rfft`. If *False*, interpret the input as a two-sided FFT. Defaults to *True*.

**boundary** : bool, optional  
 Specifies whether the input signal was extended at its boundaries by supplying a non-*None* boundary argument to *stft*. Defaults to *True*.

**time\_axis** : int, optional  
 Where the time segments of the STFT is located; the default is the last axis (i.e. `axis=-1`).

**freq\_axis** : int, optional  
 Where the frequency axis of the STFT is located; the default is the penultimate axis (i.e. `axis=-2`).

**Returns**

**t** : ndarray  
 Array of output data times.

**x** : ndarray  
 iSTFT of  $Z_{xx}$ .

**See also:**

**stft** Short Time Fourier Transform  
**check\_COLA** Check whether the Constant OverLap Add (COLA) constraint is met

**Notes**

In order to enable inversion of an STFT via the inverse STFT with *istft*, the signal windowing must obey the constraint of “Constant OverLap Add” (COLA). This ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction. Whether a choice of *window*, *nperseg*, and *noverlap* satisfy this constraint can be tested with *check\_COLA*, by using `nperseg = Zxx.shape[freq_axis]`.

An STFT which has been modified (via masking or otherwise) is not guaranteed to correspond to a exactly realizable signal. This function implements the iSTFT via the least-squares estimation algorithm detailed in [R278], which produces a signal that minimizes the mean squared error between the STFT of the returned signal and the modified STFT.

New in version 0.19.0.

**References**

[R277], [R278]

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

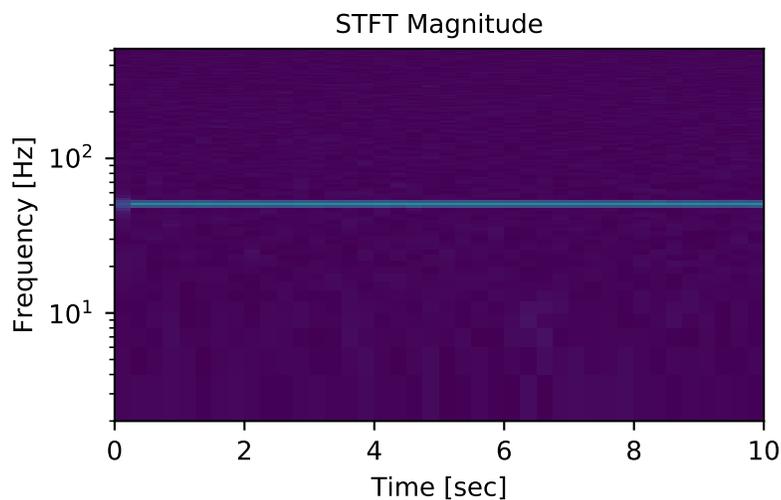

Generate a test signal, a 2 Vrms sine wave at 50Hz corrupted by 0.001 V\*\*2/Hz of white noise sampled at 1024 Hz.

```
>>> fs = 1024
>>> N = 10*fs
>>> nperseg = 512
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> carrier = amp * np.sin(2*np.pi*50*time)
>>> noise = np.random.normal(scale=np.sqrt(noise_power),
```

```
... size=time.shape)
>>> x = carrier + noise
```

Compute the STFT, and plot its magnitude

```
>>> f, t, Zxx = signal.stft(x, fs=fs, nperseg=nperseg)
>>> plt.figure()
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp)
>>> plt.ylim([f[1], f[-1]])
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.yscale('log')
>>> plt.show()
```

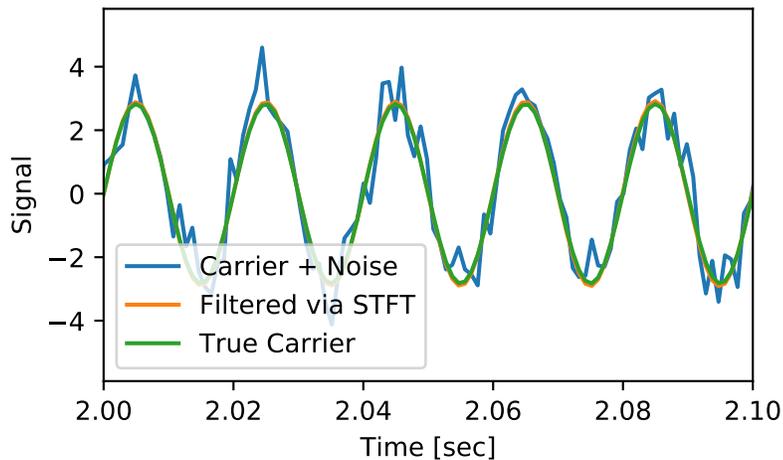

Zero the components that are 10% or less of the carrier magnitude, then convert back to a time series via inverse STFT

```
>>> Zxx = np.where(np.abs(Zxx) >= amp/10, Zxx, 0)
>>> _, xrec = signal.istft(Zxx, fs)
```

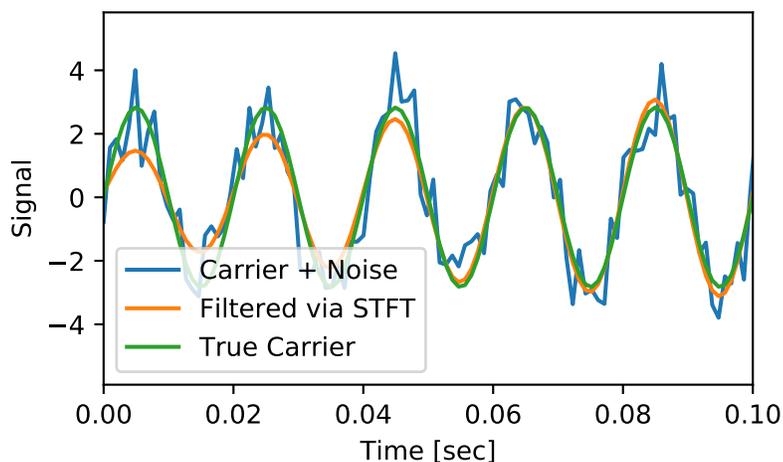

Compare the cleaned signal with the original and true carrier signals.

```
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([2, 2.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

Note that the cleaned signal does not start as abruptly as the original, since some of the coefficients of the transient were also removed:

```
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([0, 0.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

`scipy.signal.check_COLA(window, nperseg, noverlap, tol=1e-10)`

Check whether the Constant OverLap Add (COLA) constraint is met

**Parameters** **window** : str or tuple or array\_like

Desired window to use. If *window* is a string or tuple, it is passed to *get\_window* to generate the window values, which are DFT-even by default. See *get\_window* for a list of windows and required parameters. If

*window* is array\_like it will be used directly as the window and its length must be *nperseg*.

**nperseg** : int  
Length of each segment.

**noverlap** : int  
Number of points to overlap between segments.

**tol** : float, optional  
The allowed variance of a bin's weighted sum from the median bin sum.

**Returns** **verdict** : bool  
*True* if chosen combination satisfies COLA within *tol*, *False* otherwise

**See also:**

**stft** Short Time Fourier Transform  
**istft** Inverse Short Time Fourier Transform

**Notes**

In order to enable inversion of an STFT via the inverse STFT in *istft*, the signal windowing must obey the constraint of “Constant OverLap Add” (COLA). This ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction.

**Some examples of windows that satisfy COLA:**

- Rectangular window at overlap of 0, 1/2, 2/3, 3/4, ...
- Bartlett window at overlap of 1/2, 3/4, 5/6, ...
- Hann window at 1/2, 2/3, 3/4, ...
- Any Blackman family window at 2/3 overlap
- Any window with `noverlap = nperseg-1`

A very comprehensive list of other windows may be found in [R243], wherein the COLA condition is satisfied when the “Amplitude Flatness” is unity.

New in version 0.19.0.

**References**

[R242], [R243]

**Examples**

```
>>> from scipy import signal
```

Confirm COLA condition for rectangular window of 75% (3/4) overlap:

```
>>> signal.check_COLA(signal.boxcar(100), 100, 75)
True
```

COLA is not true for 25% (1/4) overlap, though:

```
>>> signal.check_COLA(signal.boxcar(100), 100, 25)
False
```

“Symmetrical” Hann window (for filter design) is not COLA:

```
>>> signal.check_COLA(signal.hann(120, sym=True), 120, 60)
False
```

“Periodic” or “DFT-even” Hann window (for FFT analysis) is COLA for overlap of 1/2, 2/3, 3/4, etc.:

```
>>> signal.check_COLA(signal.hann(120, sym=False), 120, 60)
True
```

```
>>> signal.check_COLA(signal.hann(120, sym=False), 120, 80)
True
```

```
>>> signal.check_COLA(signal.hann(120, sym=False), 120, 90)
True
```

## 5.21 Sparse matrices (scipy.sparse)

SciPy 2-D sparse matrix package for numeric data.

### 5.21.1 Contents

#### Sparse matrix classes

<code>bsr_matrix</code> (arg1[, shape, dtype, copy, blocksize])	Block Sparse Row matrix
<code>coo_matrix</code> (arg1[, shape, dtype, copy])	A sparse matrix in COOrdinate format.
<code>csc_matrix</code> (arg1[, shape, dtype, copy])	Compressed Sparse Column matrix
<code>csr_matrix</code> (arg1[, shape, dtype, copy])	Compressed Sparse Row matrix
<code>dia_matrix</code> (arg1[, shape, dtype, copy])	Sparse matrix with DIAGonal storage
<code>dok_matrix</code> (arg1[, shape, dtype, copy])	Dictionary Of Keys based sparse matrix.
<code>lil_matrix</code> (arg1[, shape, dtype, copy])	Row-based linked list sparse matrix
<code>spmatrix</code> ([maxprint])	This class provides a base class for all sparse matrices.

**class** `scipy.sparse.bsr_matrix` (*arg1*, *shape=None*, *dtype=None*, *copy=False*, *blocksize=None*)

Block Sparse Row matrix

*This can be instantiated in several ways:*

`bsr_matrix(D, [blocksize=(R,C)])`

where D is a dense matrix or 2-D ndarray.

`bsr_matrix(S, [blocksize=(R,C)])`

with another sparse matrix S (equivalent to S.tobsr())

`bsr_matrix((M, N), [blocksize=(R,C), dtype])`

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

`bsr_matrix((data, ij), [blocksize=(R,C), shape=(M, N)])`

where data and ij satisfy `a[ij[0, k], ij[1, k]] = data[k]`

`bsr_matrix((data, indices, indptr), [shape=(M, N)])`

is the standard BSR representation where the block column indices for row i are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding block values are stored in `data[indptr[i]: indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

*Notes*

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

**Summary of BSR format**

The Block Compressed Row (BSR) format is very similar to the Compressed Sparse Row (CSR) format. BSR is appropriate for sparse matrices with dense sub matrices like the last example below. Block matrices often arise in vector-valued finite element discretizations. In such cases, BSR is considerably more efficient than CSR and CSC for many sparse arithmetic operations.

**Blocksize**

The blocksize (R,C) must evenly divide the shape of the matrix (M,N). That is, R and C must satisfy the relationship  $M \% R = 0$  and  $N \% C = 0$ .

If no blocksize is specified, a simple heuristic is applied to determine an appropriate blocksize.

*Examples*

```
>>> from scipy.sparse import bsr_matrix
>>> bsr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> row = np.array([0, 0, 1, 2, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> bsr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

```
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6]).repeat(4).reshape(6, 2, 2)
>>> bsr_matrix((data, indices, indptr), shape=(6, 6)).toarray()
array([[1, 1, 0, 0, 2, 2],
       [1, 1, 0, 0, 2, 2],
       [0, 0, 0, 0, 3, 3],
       [0, 0, 0, 0, 3, 3],
       [4, 4, 5, 5, 6, 6],
       [4, 4, 5, 5, 6, 6]])
```

*Attributes*

<i>shape</i>	Get shape of a matrix.
<i>nnz</i>	Number of stored values, including explicit zeros.
<i>has_sorted_indices</i>	Determine whether the matrix has sorted indices

`bsr_matrix.shape`  
Get shape of a matrix.

`bsr_matrix.nnz`  
Number of stored values, including explicit zeros.

**See also:****count\_nonzero**

Number of non-zero entries

**bsr\_matrix.has\_sorted\_indices**

Determine whether the matrix has sorted indices

**Returns**

- True: if the indices of the matrix are in sorted order
- False: otherwise

<b>dtype</b>	(dtype) Data type of the matrix
<b>ndim</b>	(int) Number of dimensions (this is always 2)
<b>data</b>	Data array of the matrix
<b>indices</b>	BSR format index array
<b>indptr</b>	BSR format index pointer array
<b>blocksize</b>	Block size of the matrix

**Methods**

<i>arcsin()</i>	Element-wise arcsin.
<i>arcsinh()</i>	Element-wise arcsinh.
<i>arctan()</i>	Element-wise arctan.
<i>arctanh()</i>	Element-wise arctanh.
<i>argmax([axis, out])</i>	Return indices of maximum elements along an axis.
<i>argmin([axis, out])</i>	Return indices of minimum elements along an axis.
<i>asformat(format)</i>	Return this matrix in a given sparse format
<i>asfptype()</i>	Upcast matrix to a floating point format (if necessary)
<i>astype(dtype[, casting, copy])</i>	Cast the matrix elements to a specified type.
<i>ceil()</i>	Element-wise ceil.
<i>check_format([full_check])</i>	check whether the matrix format is valid
<i>conj()</i>	Element-wise complex conjugation.
<i>conjugate()</i>	Element-wise complex conjugation.
<i>copy()</i>	Returns a copy of this matrix.
<i>count_nonzero()</i>	Number of non-zero entries, equivalent to
<i>deg2rad()</i>	Element-wise deg2rad.
<i>diagonal([k])</i>	Returns the k-th diagonal of the matrix.
<i>dot(other)</i>	Ordinary dot product
<i>eliminate_zeros()</i>	Remove zero elements in-place.
<i>expm1()</i>	Element-wise expm1.
<i>floor()</i>	Element-wise floor.
<i>getH()</i>	Return the Hermitian transpose of this matrix.
<i>get_shape()</i>	Get shape of a matrix.
<i>getcol(j)</i>	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
<i>getformat()</i>	Format of a matrix representation as a string.
<i>getmaxprint()</i>	Maximum number of elements to display when printed.
<i>getnnz([axis])</i>	Number of stored values, including explicit zeros.
<i>getrow(i)</i>	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
<i>log1p()</i>	Element-wise log1p.
<i>matmat(*args, **kwargs)</i>	<i>matmat</i> is deprecated!
<i>matvec(*args, **kwargs)</i>	<i>matvec</i> is deprecated!

Continued on next page

Table 5.164 – continued from previous page

<code>max([axis, out])</code>	Return the maximum of the matrix or maximum along an axis.
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>min([axis, out])</code>	Return the minimum of the matrix or maximum along an axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix, vector, or scalar.
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	This function performs element-wise power.
<code>prune()</code>	Remove empty space after all non-zero elements.
<code>rad2deg()</code>	Element-wise rad2deg.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>rint()</code>	Element-wise rint.
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sign()</code>	Element-wise sign.
<code>sin()</code>	Element-wise sin.
<code>sinh()</code>	Element-wise sinh.
<code>sort_indices()</code>	Sort the indices of this matrix <i>in place</i>
<code>sorted_indices()</code>	Return a copy of this matrix with sorted indices
<code>sqrt()</code>	Element-wise sqrt.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>sum_duplicates()</code>	Eliminate duplicate matrix entries by adding them together
<code>tan()</code>	Element-wise tan.
<code>tanh()</code>	Element-wise tanh.
<code>toarray([order, out])</code>	Return a dense ndarray representation of this matrix.
<code>tobsr([blocksize, copy])</code>	Convert this matrix into Block Sparse Row Format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise trunc.

`bsr_matrix.arcsin()`

Element-wise arcsin.

See `numpy.arcsin` for more information.

`bsr_matrix.arcsinh()`

Element-wise arcsinh.

See `numpy.arcsinh` for more information.

`bsr_matrix.arctan()`  
Element-wise arctan.

See `numpy.arctan` for more information.

`bsr_matrix.arctanh()`  
Element-wise arctanh.

See `numpy.arctanh` for more information.

`bsr_matrix.argmax` (*axis=None, out=None*)  
Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters**    **axis** : {-2, -1, 0, 1, None}, optional  
Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

**out** : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**        **ind** : np.matrix or int  
Indices of maximum elements. If matrix, its size along *axis* is 1.

`bsr_matrix.argmin` (*axis=None, out=None*)  
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**    **axis** : {-2, -1, 0, 1, None}, optional  
Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

**out** : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**        **ind** : np.matrix or int  
Indices of minimum elements. If matrix, its size along *axis* is 1.

`bsr_matrix.asformat` (*format*)  
Return this matrix in a given sparse format

**Parameters**    **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for `csr_matrix` format
- “csc” for `csc_matrix` format
- “lil” for `lil_matrix` format
- “dok” for `dok_matrix` format and so on

`bsr_matrix.asfptype()`  
Upcast matrix to a floating point format (if necessary)

`bsr_matrix.astype` (*dtype, casting='unsafe', copy=True*)  
Cast the matrix elements to a specified type.

**Parameters**    **dtype** : string or numpy dtype  
Typecode or data-type to which to cast the data.

**casting** : { 'no', 'equiv', 'safe', 'same\_kind', 'unsafe' }, optional

Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same\_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

**copy** : bool, optional

If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

`bsr_matrix.ceil()`

Element-wise ceil.

See `numpy.ceil` for more information.

`bsr_matrix.check_format` (*full\_check=True*)

check whether the matrix format is valid

**Parameters:**

***full\_check***: True - rigorous check, O(N) operations : default False - basic check, O(1) operations

`bsr_matrix.conj()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`bsr_matrix.conjugate()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`bsr_matrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`bsr_matrix.count_nonzero()`

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`bsr_matrix.deg2rad()`

Element-wise deg2rad.

See `numpy.deg2rad` for more information.

`bsr_matrix.diagonal` (*k=0*)

Returns the k-th diagonal of the matrix.

**Parameters** **k** : int, optional

Which diagonal to set, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

**See also:**

[\*numpy.diagonal\*](#)

Equivalent numpy function.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

`bsr_matrix.dot(other)`  
Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`bsr_matrix.eliminate_zeros()`  
Remove zero elements in-place.

`bsr_matrix.expm1()`  
Element-wise `expm1`.

See `numpy.expm1` for more information.

`bsr_matrix.floor()`  
Element-wise floor.

See `numpy.floor` for more information.

`bsr_matrix.getH()`  
Return the Hermitian transpose of this matrix.

**See also:**

**`np.matrix.getH`**  
NumPy's implementation of `getH` for matrices

`bsr_matrix.get_shape()`  
Get shape of a matrix.

`bsr_matrix.getcol(j)`  
Returns a copy of column *j* of the matrix, as an (*m* x 1) sparse matrix (column vector).

`bsr_matrix.getformat()`  
Format of a matrix representation as a string.

`bsr_matrix.getmaxprint()`  
Maximum number of elements to display when printed.

`bsr_matrix.getnnz(axis=None)`  
Number of stored values, including explicit zeros.

**Parameters** `axis`: None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

**count\_nonzero**

Number of non-zero entries

`bsr_matrix.getrow(i)`

Returns a copy of row *i* of the matrix, as a (1 x n) sparse matrix (row vector).

`bsr_matrix.log1p()`

Element-wise log1p.

See `numpy.log1p` for more information.

`bsr_matrix.matmat(*args, **kws)`

*matmat* is deprecated! BSR *matmat* is deprecated in scipy 0.19.0. Use `*` operator instead.

Multiply this sparse matrix by other matrix.

`bsr_matrix.matvec(*args, **kws)`

*matvec* is deprecated! BSR *matvec* is deprecated in scipy 0.19.0. Use `*` operator instead.

Multiply matrix by vector.

`bsr_matrix.max(axis=None, out=None)`

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. *axis* = *None*).

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amax** : `coo_matrix` or scalar

Maximum of *a*. If *axis* is *None*, the result is a scalar value. If *axis* is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

**min** The minimum value of a sparse matrix along a given axis.

**`np.matrix.max`**

NumPy's implementation of 'max' for matrices

`bsr_matrix.maximum(other)`

Element-wise maximum between this and another matrix.

`bsr_matrix.mean(axis=None, dtype=None, out=None)`

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis* = *None*).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

**out** : `np.matrix`, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

**np.matrix.mean**

NumPy's implementation of 'mean' for matrices

**bsr\_matrix.min** (*axis=None, out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. *axis = None*).

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amin** : coo\_matrix or scalar

Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse.coo\_matrix of dimension `a.ndim - 1`.

**See also:**

**max** The maximum value of a sparse matrix along a given axis.

**np.matrix.min**

NumPy's implementation of 'min' for matrices

**bsr\_matrix.minimum** (*other*)

Element-wise minimum between this and another matrix.

**bsr\_matrix.multiply** (*other*)

Point-wise multiplication by another matrix, vector, or scalar.

**bsr\_matrix.nonzero** ()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**bsr\_matrix.power** (*n, dtype=None*)

This function performs element-wise power.

**Parameters** **n** : n is a scalar

**dtype** : If dtype is not specified, the current dtype will be preserved.

**bsr\_matrix.prune** ()

Remove empty space after all non-zero elements.

**bsr\_matrix.rad2deg** ()

Element-wise rad2deg.

See `numpy.rad2deg` for more information.

**bsr\_matrix.reshape** (*shape, order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints  
 The new shape should be compatible with the original shape.  
**order** : 'C', optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.  
**Returns** **reshaped\_matrix** : *self* with the new dimensions of *shape*

**See also:**

**`np.matrix.reshape`**  
 NumPy's implementation of 'reshape' for matrices

`bsr_matrix.rint()`  
 Element-wise rint.

See `numpy rint` for more information.

`bsr_matrix.set_shape(shape)`  
 See *reshape*.

`bsr_matrix.setdiag(values, k=0)`  
 Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : array\_like  
 New values of the diagonal elements.  
 Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.  
 If a scalar value is given, all of the diagonal is set to it.  
**k** : int, optional  
 Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

`bsr_matrix.sign()`  
 Element-wise sign.

See `numpy.sign` for more information.

`bsr_matrix.sin()`  
 Element-wise sin.

See `numpy.sin` for more information.

`bsr_matrix.sinh()`  
 Element-wise sinh.

See `numpy.sinh` for more information.

`bsr_matrix.sort_indices()`  
 Sort the indices of this matrix *in place*

`bsr_matrix.sorted_indices()`  
 Return a copy of this matrix with sorted indices

`bsr_matrix.sqrt()`  
 Element-wise sqrt.

See `numpy.sqrt` for more information.

`bsr_matrix.sum(axis=None, dtype=None, out=None)`  
 Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).

**dtype** : dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

**sum\_along\_axis** : np.matrix

A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

***np.matrix.sum***

NumPy's implementation of 'sum' for matrices

***bsr\_matrix.sum\_duplicates()***

Eliminate duplicate matrix entries by adding them together

The is an *in place* operation

***bsr\_matrix.tan()***

Element-wise tan.

See `numpy.tan` for more information.

***bsr\_matrix.tanh()***

Element-wise tanh.

See `numpy.tanh` for more information.

***bsr\_matrix.toarray (order=None, out=None)***

Return a dense ndarray representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns**

**arr** : ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

***bsr\_matrix.tobsr (blocksize=None, copy=False)***

Convert this matrix into Block Sparse Row Format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

If `blocksize=(R, C)` is provided, it will be used for determining block size of the `bsr_matrix`.

`bsr_matrix.tocoo (copy=True)`

Convert this matrix to COOrdinate format.

When `copy=False` the data array will be shared between this matrix and the resultant `coo_matrix`.

`bsr_matrix.tocsc (copy=False)`

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`bsr_matrix.tocsr (copy=False)`

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`bsr_matrix.todense (order=None, out=None)`

Return a dense matrix representation of this matrix.

**Parameters** `order` : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

`out` : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns** `arr` : numpy.matrix, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`bsr_matrix.todia (copy=False)`

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`bsr_matrix.todok (copy=False)`

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`bsr_matrix.tolil (copy=False)`

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`bsr_matrix.ttranspose (axes=None, copy=False)`

Reverses the dimensions of the sparse matrix.

**Parameters** `axes` : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

`copy` : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending

**Returns** `p` : *self* with the dimensions reversed.

See also:

**`np.matrix.transpose`**

NumPy's implementation of 'transpose' for matrices

`bsr_matrix.trunc()`

Element-wise trunc.

See `numpy.trunc` for more information.

**class** `scipy.sparse.coo_matrix` (*arg1*, *shape=None*, *dtype=None*, *copy=False*)  
A sparse matrix in COOrdinate format.

Also known as the 'ijv' or 'triplet' format.

*This can be instantiated in several ways:*

**`coo_matrix(D)`**

with a dense matrix D

**`coo_matrix(S)`** with another sparse matrix S (equivalent to `S.tocoo()`)

**`coo_matrix((M, N), [dtype])`**

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

**`coo_matrix((data, (i, j)), [shape=(M, N)])`**

*to construct from three arrays:*

1.`data[:]` the entries of the matrix, in any order

2.`i[:]` the row indices of the matrix entries

3.`j[:]` the column indices of the matrix entries

Where  $A[i[k], j[k]] = data[k]$ . When shape is not specified, it is inferred from the index arrays

### Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

### Advantages of the COO format

- facilitates fast conversion among sparse formats
- permits duplicate entries (see example)
- very fast conversion to and from CSR/CSC formats

### Disadvantages of the COO format

• *does not directly support:*

–arithmetic operations

–slicing

### Intended Usage

- COO is a fast format for constructing sparse matrices
- Once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
- By default when converting to CSR or CSC format, duplicate (i,j) entries will be summed together. This facilitates efficient construction of finite element matrices and the like. (see example)

**Examples**

```
>>> # Constructing an empty matrix
>>> from scipy.sparse import coo_matrix
>>> coo_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> # Constructing a matrix using ijv format
>>> row = np.array([0, 3, 1, 0])
>>> col = np.array([0, 3, 1, 2])
>>> data = np.array([4, 5, 7, 9])
>>> coo_matrix((data, (row, col)), shape=(4, 4)).toarray()
array([[4, 0, 9, 0],
       [0, 7, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 5]])
```

```
>>> # Constructing a matrix with duplicate indices
>>> row = np.array([0, 0, 1, 3, 1, 0, 0])
>>> col = np.array([0, 2, 1, 3, 1, 0, 0])
>>> data = np.array([1, 1, 1, 1, 1, 1, 1])
>>> coo = coo_matrix((data, (row, col)), shape=(4, 4))
>>> # Duplicate indices are maintained until implicitly or explicitly summed
>>> np.max(coo.data)
1
>>> coo.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

**Attributes**

<i>shape</i>	Get shape of a matrix.
<i>nnz</i>	Number of stored values, including explicit zeros.

`coo_matrix.shape`  
Get shape of a matrix.

`coo_matrix.nnz`  
Number of stored values, including explicit zeros.

**See also:**

`count_nonzero`  
Number of non-zero entries

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	COO format data array of the matrix
<code>row</code>	COO format row index array of the matrix
<code>col</code>	COO format column index array of the matrix

**Methods**

<i>arcsin()</i>	Element-wise arcsin.
<i>arcsinh()</i>	Element-wise arcsinh.
<i>arctan()</i>	Element-wise arctan.
<i>arctanh()</i>	Element-wise arctanh.
<i>argmax</i> ([axis, out])	Return indices of maximum elements along an axis.
<i>argmin</i> ([axis, out])	Return indices of minimum elements along an axis.
<i>asformat</i> (format)	Return this matrix in a given sparse format
<i>asfptype</i> ()	Upcast matrix to a floating point format (if necessary)
<i>astype</i> (dtype[, casting, copy])	Cast the matrix elements to a specified type.
<i>ceil</i> ()	Element-wise ceil.
<i>conj</i> ()	Element-wise complex conjugation.
<i>conjugate</i> ()	Element-wise complex conjugation.
<i>copy</i> ()	Returns a copy of this matrix.
<i>count_nonzero</i> ()	Number of non-zero entries, equivalent to
<i>deg2rad</i> ()	Element-wise deg2rad.
<i>diagonal</i> ([k])	Returns the k-th diagonal of the matrix.
<i>dot</i> (other)	Ordinary dot product
<i>eliminate_zeros</i> ()	Remove zero entries from the matrix
<i>expm1</i> ()	Element-wise expm1.
<i>floor</i> ()	Element-wise floor.
<i>getH</i> ()	Return the Hermitian transpose of this matrix.
<i>get_shape</i> ()	Get shape of a matrix.
<i>getcol</i> (j)	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
<i>getformat</i> ()	Format of a matrix representation as a string.
<i>getmaxprint</i> ()	Maximum number of elements to display when printed.
<i>getnnz</i> ([axis])	Number of stored values, including explicit zeros.
<i>getrow</i> (i)	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
<i>log1p</i> ()	Element-wise log1p.
<i>max</i> ([axis, out])	Return the maximum of the matrix or maximum along an axis.
<i>maximum</i> (other)	Element-wise maximum between this and another matrix.
<i>mean</i> ([axis, dtype, out])	Compute the arithmetic mean along the specified axis.
<i>min</i> ([axis, out])	Return the minimum of the matrix or maximum along an axis.
<i>minimum</i> (other)	Element-wise minimum between this and another matrix.
<i>multiply</i> (other)	Point-wise multiplication by another matrix
<i>nonzero</i> ()	nonzero indices
<i>power</i> (n[, dtype])	This function performs element-wise power.
<i>rad2deg</i> ()	Element-wise rad2deg.
<i>reshape</i> (shape[, order])	Gives a new shape to a sparse matrix without changing its data.
<i>rint</i> ()	Element-wise rint.
<i>set_shape</i> (shape)	See <i>reshape</i> .
<i>setdiag</i> (values[, k])	Set diagonal or off-diagonal elements of the array.
<i>sign</i> ()	Element-wise sign.
<i>sin</i> ()	Element-wise sin.

Continued on next page

Table 5.166 – continued from previous page

<code>sinh()</code>	Element-wise sinh.
<code>sqrt()</code>	Element-wise sqrt.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>sum_duplicates()</code>	Eliminate duplicate matrix entries by adding them together
<code>tan()</code>	Element-wise tan.
<code>tanh()</code>	Element-wise tanh.
<code>toarray([order, out])</code>	See the docstring for <code>spmatrix.toarray</code> .
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAGONAL format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LIInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise trunc.

`coo_matrix.arcsin()`  
Element-wise arcsin.

See `numpy.arcsin` for more information.

`coo_matrix.arcsinh()`  
Element-wise arcsinh.

See `numpy.arcsinh` for more information.

`coo_matrix.arctan()`  
Element-wise arctan.

See `numpy.arctan` for more information.

`coo_matrix.arctanh()`  
Element-wise arctanh.

See `numpy.arctanh` for more information.

`coo_matrix.argmax(axis=None, out=None)`  
Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.

**out** : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix of int  
Indices of maximum elements. If matrix, its size along *axis* is 1.

`coo_matrix.argmin(axis=None, out=None)`  
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
 Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

**out** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
 Indices of minimum elements. If matrix, its size along *axis* is 1.

`coo_matrix.asformat` (*format*)

Return this matrix in a given sparse format

**Parameters** **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for csr\_matrix format
- “csc” for csc\_matrix format
- “lil” for lil\_matrix format
- “dok” for dok\_matrix format and so on

`coo_matrix.asfptype` ()

Upcast matrix to a floating point format (if necessary)

`coo_matrix.astype` (*dtype*, *casting*='unsafe', *copy*=True)

Cast the matrix elements to a specified type.

**Parameters** **dtype** : string or numpy dtype  
 Typecode or data-type to which to cast the data.

**casting** : {'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional  
 Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same\_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

**copy** : bool, optional  
 If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

`coo_matrix.ceil` ()

Element-wise ceil.

See `numpy.ceil` for more information.

`coo_matrix.conj` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`coo_matrix.conjugate` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`coo_matrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`coo_matrix.count_nonzero()`

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`coo_matrix.deg2rad()`

Element-wise `deg2rad`.

See `numpy.deg2rad` for more information.

`coo_matrix.diagonal(k=0)`

Returns the k-th diagonal of the matrix.

**Parameters** `k` : int, optional

Which diagonal to set, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

**See also:**

[\*numpy.diagonal\*](#)

Equivalent numpy function.

#### Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

`coo_matrix.dot(other)`

Ordinary dot product

#### Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`coo_matrix.eliminate_zeros()`

Remove zero entries from the matrix

This is an *in place* operation

`coo_matrix.expm1()`

Element-wise `expm1`.

See `numpy.expm1` for more information.

`coo_matrix.floor()`

Element-wise floor.

See `numpy.floor` for more information.

`coo_matrix.getH()`

Return the Hermitian transpose of this matrix.

**See also:**

**`np.matrix.getH`**

NumPy's implementation of `getH` for matrices

`coo_matrix.get_shape()`

Get shape of a matrix.

`coo_matrix.getcol(j)`

Returns a copy of column `j` of the matrix, as an  $(m \times 1)$  sparse matrix (column vector).

`coo_matrix.getformat()`

Format of a matrix representation as a string.

`coo_matrix.getmaxprint()`

Maximum number of elements to display when printed.

`coo_matrix.getnnz(axis=None)`

Number of stored values, including explicit zeros.

**Parameters** **axis** : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

**`count_nonzero`**

Number of non-zero entries

`coo_matrix.getrow(i)`

Returns a copy of row `i` of the matrix, as a  $(1 \times n)$  sparse matrix (row vector).

`coo_matrix.log1p()`

Element-wise `log1p`.

See `numpy.log1p` for more information.

`coo_matrix.max(axis=None, out=None)`

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. `axis = None`).

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amax** : `coo_matrix` or scalar

Maximum of `a`. If `axis` is None, the result is a scalar value. If `axis` is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

**`min`** The minimum value of a sparse matrix along a given axis.

**`np.matrix.max`**

NumPy's implementation of 'max' for matrices

`coo_matrix.maximum` (*other*)

Element-wise maximum between this and another matrix.

`coo_matrix.mean` (*axis=None, dtype=None, out=None*)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters**

- axis** : {-2, -1, 0, 1, None} optional  
Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).
- dtype** : data-type, optional  
Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
- out** : np.matrix, optional  
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

**`np.matrix.mean`**

NumPy's implementation of 'mean' for matrices

`coo_matrix.min` (*axis=None, out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- axis** : {-2, -1, 0, 1, None} optional  
Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. *axis = None*).
- out** : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amin** : `coo_matrix` or scalar  
Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

**max** The maximum value of a sparse matrix along a given axis.

**`np.matrix.min`**

NumPy's implementation of 'min' for matrices

`coo_matrix.minimum` (*other*)

Element-wise minimum between this and another matrix.

`coo_matrix.multiply` (*other*)

Point-wise multiplication by another matrix

`coo_matrix.nonzero` ()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`coo_matrix.power` (*n*, *dtype=None*)

This function performs element-wise power.

**Parameters** **n** : *n* is a scalar  
**dtype** : If *dtype* is not specified, the current *dtype* will be preserved.

`coo_matrix.rad2deg` ()

Element-wise `rad2deg`.

See `numpy.rad2deg` for more information.

`coo_matrix.reshape` (*shape*, *order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints  
 The new shape should be compatible with the original shape.  
**order** : 'C', optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **reshaped\_matrix** : *self* with the new dimensions of *shape*

**See also:**

**`np.matrix.reshape`**

NumPy's implementation of 'reshape' for matrices

`coo_matrix.rint` ()

Element-wise `rint`.

See `numpy.rint` for more information.

`coo_matrix.set_shape` (*shape*)

See `reshape`.

`coo_matrix.setdiag` (*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : *array\_like*  
 New values of the diagonal elements.  
 Values may have any length. If the diagonal is longer than *values*, then the remaining diagonal entries will not be set. If *values* is longer than the diagonal, then the remaining values are ignored.  
 If a scalar value is given, all of the diagonal is set to it.

**k** : int, optional

Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

`coo_matrix.sign` ()

Element-wise `sign`.

See `numpy.sign` for more information.

`coo_matrix.sin` ()

Element-wise `sin`.

See `numpy.sin` for more information.

`coo_matrix.sinh()`  
Element-wise `sinh`.

See `numpy.sinh` for more information.

`coo_matrix.sqrt()`  
Element-wise `sqrt`.

See `numpy.sqrt` for more information.

`coo_matrix.sum(axis=None, dtype=None, out=None)`  
Sum the matrix elements over a given axis.

**Parameters**

- axis** : {-2, -1, 0, 1, None} optional  
Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).
- dtype** : dtype, optional  
The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
- out** : np.matrix, optional  
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

**sum\_along\_axis** : np.matrix  
A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

**`np.matrix.sum`**  
NumPy's implementation of 'sum' for matrices

`coo_matrix.sum_duplicates()`  
Eliminate duplicate matrix entries by adding them together

This is an *in place* operation

`coo_matrix.tan()`  
Element-wise `tan`.

See `numpy.tan` for more information.

`coo_matrix.tanh()`  
Element-wise `tanh`.

See `numpy.tanh` for more information.

`coo_matrix.toarray(order=None, out=None)`  
See the docstring for `spmatrix.toarray`.

`coo_matrix.tobsr(blocksize=None, copy=False)`  
Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

`coo_matrix.tocoo` (*copy=False*)  
Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`coo_matrix.tocsc` (*copy=False*)  
Convert this matrix to Compressed Sparse Column format

Duplicate entries will be summed together.

### Examples

```
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsc()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

`coo_matrix.tocsr` (*copy=False*)  
Convert this matrix to Compressed Sparse Row format

Duplicate entries will be summed together.

### Examples

```
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsr()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

`coo_matrix.todense` (*order=None, out=None*)  
Return a dense matrix representation of this matrix.

**Parameters**    **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**        **arr** : `numpy.matrix`, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory

order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`coo_matrix.todia (copy=False)`

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`coo_matrix.todok (copy=False)`

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`coo_matrix.tolil (copy=False)`

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`coo_matrix.transpose (axes=None, copy=False)`

Reverses the dimensions of the sparse matrix.

**Parameters** `axes` : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

`copy` : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns** `p` : *self* with the dimensions reversed.

**See also:**

**`np.matrix.transpose`**

NumPy's implementation of 'transpose' for matrices

`coo_matrix.trunc ()`

Element-wise trunc.

See `numpy.trunc` for more information.

**class** `scipy.sparse.csc_matrix (arg1, shape=None, dtype=None, copy=False)`

Compressed Sparse Column matrix

This can be instantiated in several ways:

`csc_matrix(D)` with a dense matrix or rank-2 ndarray *D*  
`csc_matrix(S)` with another sparse matrix *S* (equivalent to `S.tocsc()`)  
`csc_matrix((M, N), [dtype])`

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.  
`csc_matrix((data, (row_ind, col_ind)), [shape=(M, N)])`

where `data`, `row_ind` and `col_ind` satisfy the relationship `a[row_ind[k],`

`col_ind[k]] = data[k]`.  
`csc_matrix((data, indices, indptr), [shape=(M, N)])`

is the standard CSC representation where the row indices for column *i* are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding values are stored in `data[indptr[i]:indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

### Advantages of the CSC format

- efficient arithmetic operations  $CSC + CSC$ ,  $CSC * CSC$ , etc.
- efficient column slicing
- fast matrix vector products (CSR, BSR may be faster)

### Disadvantages of the CSC format

- slow row slicing operations (consider CSR)
- changes to the sparsity structure are expensive (consider LIL or DOK)

### Examples

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix
>>> csc_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> row = np.array([0, 2, 2, 0, 1, 2])
>>> col = np.array([0, 0, 1, 2, 2, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

```
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

### Attributes

<code>shape</code>	Get shape of a matrix.
<code>nnz</code>	Number of stored values, including explicit zeros.
<code>has_sorted_indices</code>	Determine whether the matrix has sorted indices

`csc_matrix.shape`  
Get shape of a matrix.

`csc_matrix.nnz`  
Number of stored values, including explicit zeros.

#### See also:

`count_nonzero`  
Number of non-zero entries

`csc_matrix.has_sorted_indices`  
Determine whether the matrix has sorted indices

#### Returns

- True: if the indices of the matrix are in sorted order

•False: otherwise

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	Data array of the matrix
<code>indices</code>	CSC format index array
<code>indptr</code>	CSC format index pointer array

**Methods**

<code>arcsin()</code>	Element-wise arcsin.
<code>arcsinh()</code>	Element-wise arcsinh.
<code>arctan()</code>	Element-wise arctan.
<code>arctanh()</code>	Element-wise arctanh.
<code>argmax([axis, out])</code>	Return indices of maximum elements along an axis.
<code>argmin([axis, out])</code>	Return indices of minimum elements along an axis.
<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(dtype[, casting, copy])</code>	Cast the matrix elements to a specified type.
<code>ceil()</code>	Element-wise ceil.
<code>check_format([full_check])</code>	check whether the matrix format is valid
<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>deg2rad()</code>	Element-wise deg2rad.
<code>diagonal([k])</code>	Returns the k-th diagonal of the matrix.
<code>dot(other)</code>	Ordinary dot product
<code>eliminate_zeros()</code>	Remove zero entries from the matrix
<code>expm1()</code>	Element-wise expm1.
<code>floor()</code>	Element-wise floor.
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(i)</code>	Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
<code>log1p()</code>	Element-wise log1p.
<code>max([axis, out])</code>	Return the maximum of the matrix or maximum along an axis.
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>min([axis, out])</code>	Return the minimum of the matrix or maximum along an axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix, vector, or scalar.

Continued on next page

Table 5.168 – continued from previous page

<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	This function performs element-wise power.
<code>prune()</code>	Remove empty space after all non-zero elements.
<code>rad2deg()</code>	Element-wise rad2deg.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>rint()</code>	Element-wise rint.
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sign()</code>	Element-wise sign.
<code>sin()</code>	Element-wise sin.
<code>sinh()</code>	Element-wise sinh.
<code>sort_indices()</code>	Sort the indices of this matrix <i>in place</i>
<code>sorted_indices()</code>	Return a copy of this matrix with sorted indices
<code>sqrt()</code>	Element-wise sqrt.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>sum_duplicates()</code>	Eliminate duplicate matrix entries by adding them together
<code>tan()</code>	Element-wise tan.
<code>tanh()</code>	Element-wise tanh.
<code>toarray([order, out])</code>	Return a dense ndarray representation of this matrix.
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise trunc.

`csc_matrix.arcsin()`

Element-wise arcsin.

See `numpy.arcsin` for more information.

`csc_matrix.arcsinh()`

Element-wise arcsinh.

See `numpy.arcsinh` for more information.

`csc_matrix.arctan()`

Element-wise arctan.

See `numpy.arctan` for more information.

`csc_matrix.arctanh()`

Element-wise arctanh.

See `numpy.arctanh` for more information.

`csc_matrix.argmax(axis=None, out=None)`

Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
 Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

**out** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
 Indices of maximum elements. If matrix, its size along *axis* is 1.

`csc_matrix.argmax` (*axis=None, out=None*)

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
 Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

**out** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
 Indices of minimum elements. If matrix, its size along *axis* is 1.

`csc_matrix.asformat` (*format*)

Return this matrix in a given sparse format

**Parameters** **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for csr\_matrix format
- “csc” for csc\_matrix format
- “lil” for lil\_matrix format
- “dok” for dok\_matrix format and so on

`csc_matrix.asfptype` ()

Upcast matrix to a floating point format (if necessary)

`csc_matrix.astype` (*dtype, casting='unsafe', copy=True*)

Cast the matrix elements to a specified type.

**Parameters** **dtype** : string or numpy dtype  
 Typecode or data-type to which to cast the data.

**casting** : {'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional  
 Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same\_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

**copy** : bool, optional

If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

`csc_matrix.ceil()`  
Element-wise ceil.

See `numpy.ceil` for more information.

`csc_matrix.check_format` (*full\_check=True*)  
check whether the matrix format is valid

**Parameters** **full\_check** : bool, optional  
If *True*, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default *True*).

`csc_matrix.conj()`  
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`csc_matrix.conjugate()`  
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`csc_matrix.copy()`  
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`csc_matrix.count_nonzero()`  
Number of non-zero entries, equivalent to  
`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`csc_matrix.deg2rad()`  
Element-wise `deg2rad`.

See `numpy.deg2rad` for more information.

`csc_matrix.diagonal` (*k=0*)  
Returns the *k*-th diagonal of the matrix.

**Parameters** **k** : int, optional  
Which diagonal to set, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

**See also:**

[\*numpy.diagonal\*](#)  
Equivalent `numpy` function.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

`csc_matrix.dot` (*other*)  
 Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`csc_matrix.eliminate_zeros` ()  
 Remove zero entries from the matrix

This is an *in place* operation

`csc_matrix.expm1` ()  
 Element-wise expm1.

See `numpy.expm1` for more information.

`csc_matrix.floor` ()  
 Element-wise floor.

See `numpy.floor` for more information.

`csc_matrix.getH` ()  
 Return the Hermitian transpose of this matrix.

**See also:**

`np.matrix.getH`  
 NumPy's implementation of *getH* for matrices

`csc_matrix.get_shape` ()  
 Get shape of a matrix.

`csc_matrix.getcol` (*i*)  
 Returns a copy of column *i* of the matrix, as a (m x 1) CSC matrix (column vector).

`csc_matrix.getformat` ()  
 Format of a matrix representation as a string.

`csc_matrix.getmaxprint` ()  
 Maximum number of elements to display when printed.

`csc_matrix.getnnz` (*axis=None*)  
 Number of stored values, including explicit zeros.

**Parameters** `axis` : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

`count_nonzero`  
 Number of non-zero entries

`csc_matrix.getrow` (*i*)  
 Returns a copy of row *i* of the matrix, as a (1 x n) CSR matrix (row vector).

`csc_matrix.log1p()`  
Element-wise log1p.

See `numpy.log1p` for more information.

`csc_matrix.max` (*axis=None, out=None*)

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional  
Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. *axis = None*).

**out** : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amax** : `coo_matrix` or scalar  
Maximum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

**min** The minimum value of a sparse matrix along a given axis.

**`np.matrix.max`**

NumPy's implementation of 'max' for matrices

`csc_matrix.maximum` (*other*)

Element-wise maximum between this and another matrix.

`csc_matrix.mean` (*axis=None, dtype=None, out=None*)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional  
Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional  
Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.

**out** : `np.matrix`, optional  
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : `np.matrix`

**See also:**

**`np.matrix.mean`**

NumPy's implementation of 'mean' for matrices

`csc_matrix.min` (*axis=None, out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional  
Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. *axis = None*).

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

**amin** : `coo_matrix` or scalar

Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

**max** The maximum value of a sparse matrix along a given axis.

**`np.matrix.min`**

NumPy's implementation of 'min' for matrices

`csc_matrix.minimum` (*other*)

Element-wise minimum between this and another matrix.

`csc_matrix.multiply` (*other*)

Point-wise multiplication by another matrix, vector, or scalar.

`csc_matrix.nonzero` ()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`csc_matrix.power` (*n*, *dtype=None*)

This function performs element-wise power.

**Parameters** **n** : *n* is a scalar

**dtype** : If *dtype* is not specified, the current *dtype* will be preserved.

`csc_matrix.prune` ()

Remove empty space after all non-zero elements.

`csc_matrix.rad2deg` ()

Element-wise rad2deg.

See `numpy.rad2deg` for more information.

`csc_matrix.reshape` (*shape*, *order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints

The new shape should be compatible with the original shape.

**order** : 'C', optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **reshaped\_matrix** : *self* with the new dimensions of *shape*

**See also:**

**`np.matrix.reshape`**

NumPy's implementation of 'reshape' for matrices

`csc_matrix.rint()`

Element-wise rint.

See `numpy rint` for more information.

`csc_matrix.set_shape(shape)`

See `reshape`.

`csc_matrix.setdiag(values, k=0)`

Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : array\_like

New values of the diagonal elements.

Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values is longer than the diagonal, then the remaining values are ignored.

If a scalar value is given, all of the diagonal is set to it.

**k** : int, optional

Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

`csc_matrix.sign()`

Element-wise sign.

See `numpy.sign` for more information.

`csc_matrix.sin()`

Element-wise sin.

See `numpy.sin` for more information.

`csc_matrix.sinh()`

Element-wise sinh.

See `numpy.sinh` for more information.

`csc_matrix.sort_indices()`

Sort the indices of this matrix *in place*

`csc_matrix.sorted_indices()`

Return a copy of this matrix with sorted indices

`csc_matrix.sqrt()`

Element-wise sqrt.

See `numpy.sqrt` for more information.

`csc_matrix.sum(axis=None, dtype=None, out=None)`

Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. `axis = None`).

**dtype** : dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of `a` is used by default unless `a` has an integer dtype of less precision than the default platform integer. In that case, if `a` is signed then the platform integer is used while if `a` is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional

**Returns** `sum_along_axis`: `np.matrix`  
 Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
 A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

`np.matrix.sum`

NumPy's implementation of 'sum' for matrices

`csc_matrix.sum_duplicates()`

Eliminate duplicate matrix entries by adding them together

The is an *in place* operation

`csc_matrix.tan()`

Element-wise tan.

See `numpy.tan` for more information.

`csc_matrix.tanh()`

Element-wise tanh.

See `numpy.tanh` for more information.

`csc_matrix.toarray (order=None, out=None)`

Return a dense ndarray representation of this matrix.

**Parameters** `order` : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

`out` : ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns** `arr` : ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

`csc_matrix.tobsr (blocksize=None, copy=False)`

Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

`csc_matrix.tocoo (copy=True)`

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`csc_matrix.tocsc (copy=False)`

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`csc_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`csc_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters**    **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are

**Returns**        **arr** : `numpy.matrix`, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`csc_matrix.todia` (*copy=False*)

Convert this matrix to sparse DIAgonal format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`csc_matrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`csc_matrix.tolil` (*copy=False*)

Convert this matrix to LInked List format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`csc_matrix.transpose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters**    **axes** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**        **p** : *self* with the dimensions reversed.

**See also:**

**`np.matrix.transpose`**

NumPy's implementation of 'transpose' for matrices

`csc_matrix.trunc` ()

Element-wise trunc.

See `numpy.trunc` for more information.

**class** `scipy.sparse.csr_matrix` (*arg1*, *shape=None*, *dtype=None*, *copy=False*)  
Compressed Sparse Row matrix

*This can be instantiated in several ways:*

`csr_matrix(D)` with a dense matrix or rank-2 ndarray *D*

`csr_matrix(S)` with another sparse matrix *S* (equivalent to `S.tocsr()`)

`csr_matrix((M, N), [dtype])`

to construct an empty matrix with shape *(M, N)* *dtype* is optional, defaulting to `dtype='d'`.

`csr_matrix((data, (row_ind, col_ind)), [shape=(M, N)])`

where *data*, *row\_ind* and *col\_ind* satisfy the relationship `a[row_ind[k], col_ind[k]] = data[k]`.

`csr_matrix((data, indices, indptr), [shape=(M, N)])`

is the standard CSR representation where the column indices for row *i* are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding values are stored in `data[indptr[i]:indptr[i+1]]`. If the *shape* parameter is not supplied, the matrix dimensions are inferred from the index arrays.

### Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

#### Advantages of the CSR format

- efficient arithmetic operations CSR + CSR, CSR \* CSR, etc.
- efficient row slicing
- fast matrix vector products

#### Disadvantages of the CSR format

- slow column slicing operations (consider CSC)
- changes to the sparsity structure are expensive (consider LIL or DOK)

### Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> csr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> row = np.array([0, 0, 1, 2, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

```
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

As an example of how to construct a CSR matrix incrementally, the following snippet builds a term-document matrix from texts:

```
>>> docs = [["hello", "world", "hello"], ["goodbye", "cruel", "world"]]
>>> indptr = [0]
>>> indices = []
>>> data = []
>>> vocabulary = {}
>>> for d in docs:
...     for term in d:
...         index = vocabulary.setdefault(term, len(vocabulary))
...         indices.append(index)
...         data.append(1)
...         indptr.append(len(indices))
...
>>> csr_matrix((data, indices, indptr), dtype=int).toarray()
array([[2, 1, 0, 0],
       [0, 1, 1, 1]])
```

### Attributes

<i>shape</i>	Get shape of a matrix.
<i>nnz</i>	Number of stored values, including explicit zeros.
<i>has_sorted_indices</i>	Determine whether the matrix has sorted indices

`csr_matrix.shape`  
Get shape of a matrix.

`csr_matrix.nnz`  
Number of stored values, including explicit zeros.

#### See also:

**count\_nonzero**  
Number of non-zero entries

`csr_matrix.has_sorted_indices`  
Determine whether the matrix has sorted indices

#### Returns

- True: if the indices of the matrix are in sorted order
- False: otherwise

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	CSR format data array of the matrix
<code>indices</code>	CSR format index array of the matrix
<code>indptr</code>	CSR format index pointer array of the matrix

### Methods

<code>arcsin()</code>	Element-wise arcsin.
<code>arcsinh()</code>	Element-wise arcsinh.
<code>arctan()</code>	Element-wise arctan.
<code>arctanh()</code>	Element-wise arctanh.
<code>argmax([axis, out])</code>	Return indices of maximum elements along an axis.

Continued on next page

Table 5.170 – continued from previous page

<code>argmin([axis, out])</code>	Return indices of minimum elements along an axis.
<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(dtype[, casting, copy])</code>	Cast the matrix elements to a specified type.
<code>ceil()</code>	Element-wise ceil.
<code>check_format([full_check])</code>	check whether the matrix format is valid
<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>deg2rad()</code>	Element-wise deg2rad.
<code>diagonal([k])</code>	Returns the k-th diagonal of the matrix.
<code>dot(other)</code>	Ordinary dot product
<code>eliminate_zeros()</code>	Remove zero entries from the matrix
<code>expm1()</code>	Element-wise expm1.
<code>floor()</code>	Element-wise floor.
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(i)</code>	Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
<code>log1p()</code>	Element-wise log1p.
<code>max([axis, out])</code>	Return the maximum of the matrix or maximum along an axis.
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>min([axis, out])</code>	Return the minimum of the matrix or maximum along an axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix, vector, or scalar.
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	This function performs element-wise power.
<code>prune()</code>	Remove empty space after all non-zero elements.
<code>rad2deg()</code>	Element-wise rad2deg.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>rint()</code>	Element-wise rint.
<code>set_shape(shape)</code>	See <i>reshape</i> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sign()</code>	Element-wise sign.
<code>sin()</code>	Element-wise sin.
<code>sinh()</code>	Element-wise sinh.
<code>sort_indices()</code>	Sort the indices of this matrix <i>in place</i>

Continued on next page

Table 5.170 – continued from previous page

<code>sorted_indices()</code>	Return a copy of this matrix with sorted indices
<code>sqrt()</code>	Element-wise sqrt.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>sum_duplicates()</code>	Eliminate duplicate matrix entries by adding them together
<code>tan()</code>	Element-wise tan.
<code>tanh()</code>	Element-wise tanh.
<code>toarray([order, out])</code>	Return a dense ndarray representation of this matrix.
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIagonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise trunc.

`csr_matrix.arcsin()`  
Element-wise arcsin.

See `numpy.arcsin` for more information.

`csr_matrix.arcsinh()`  
Element-wise arcsinh.

See `numpy.arcsinh` for more information.

`csr_matrix.arctan()`  
Element-wise arctan.

See `numpy.arctan` for more information.

`csr_matrix.arctanh()`  
Element-wise arctanh.

See `numpy.arctanh` for more information.

`csr_matrix.argmax(axis=None, out=None)`  
Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters** `axis` : {-2, -1, 0, 1, None}, optional  
Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

`out` : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** `ind` : np.matrix or int  
Indices of maximum elements. If matrix, its size along `axis` is 1.

`csr_matrix.argmin(axis=None, out=None)`  
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
 Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

**out** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
 Indices of minimum elements. If matrix, its size along *axis* is 1.

`csr_matrix.asformat` (*format*)

Return this matrix in a given sparse format

**Parameters** **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for csr\_matrix format
- “csc” for csc\_matrix format
- “lil” for lil\_matrix format
- “dok” for dok\_matrix format and so on

`csr_matrix.asfptype` ()

Upcast matrix to a floating point format (if necessary)

`csr_matrix.astype` (*dtype*, *casting='unsafe'*, *copy=True*)

Cast the matrix elements to a specified type.

**Parameters** **dtype** : string or numpy dtype  
 Typecode or data-type to which to cast the data.

**casting** : {'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional  
 Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same\_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

**copy** : bool, optional  
 If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

`csr_matrix.ceil` ()

Element-wise ceil.

See `numpy.ceil` for more information.

`csr_matrix.check_format` (*full\_check=True*)

check whether the matrix format is valid

**Parameters** **full\_check** : bool, optional  
 If *True*, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default *True*).

`csr_matrix.conj` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`csr_matrix.conjugate()`  
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`csr_matrix.copy()`  
Returns a copy of this matrix.  
No data/indices will be shared between the returned value and current matrix.

`csr_matrix.count_nonzero()`  
Number of non-zero entries, equivalent to  
`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`csr_matrix.deg2rad()`  
Element-wise `deg2rad`.  
See `numpy.deg2rad` for more information.

`csr_matrix.diagonal(k=0)`  
Returns the k-th diagonal of the matrix.

**Parameters** `k` : int, optional  
Which diagonal to set, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

**See also:**

`numpy.diagonal`  
Equivalent numpy function.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

`csr_matrix.dot(other)`  
Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`csr_matrix.eliminate_zeros()`  
Remove zero entries from the matrix  
This is an *in place* operation

`csr_matrix.expml()`  
Element-wise `expml`.

See `numpy.expml` for more information.

`csr_matrix.floor()`  
Element-wise `floor`.

See `numpy.floor` for more information.

`csr_matrix.getH()`  
Return the Hermitian transpose of this matrix.

**See also:**

**`np.matrix.getH`**  
NumPy's implementation of `getH` for matrices

`csr_matrix.get_shape()`  
Get shape of a matrix.

`csr_matrix.getcol(i)`  
Returns a copy of column `i` of the matrix, as a (`m` x 1) CSR matrix (column vector).

`csr_matrix.getformat()`  
Format of a matrix representation as a string.

`csr_matrix.getmaxprint()`  
Maximum number of elements to display when printed.

`csr_matrix.getnnz(axis=None)`  
Number of stored values, including explicit zeros.

**Parameters** **axis** : None, 0, or 1  
Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

**`count_nonzero`**  
Number of non-zero entries

`csr_matrix.getrow(i)`  
Returns a copy of row `i` of the matrix, as a (1 x `n`) CSR matrix (row vector).

`csr_matrix.log1p()`  
Element-wise `log1p`.

See `numpy.log1p` for more information.

`csr_matrix.max(axis=None, out=None)`  
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional  
Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. `axis = None`).

**out** : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amax** : `coo_matrix` or scalar

Maximum of  $a$ . If  $axis$  is `None`, the result is a scalar value. If  $axis$  is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

**min** The minimum value of a sparse matrix along a given axis.

**`np.matrix.max`**

NumPy's implementation of 'max' for matrices

`csr_matrix.maximum` (*other*)

Element-wise maximum between this and another matrix.

`csr_matrix.mean` ( $axis=None$ ,  $dtype=None$ ,  $out=None$ )

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e.  $axis = None$ ).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.

**out** : `np.matrix`, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : `np.matrix`

**See also:**

**`np.matrix.mean`**

NumPy's implementation of 'mean' for matrices

`csr_matrix.min` ( $axis=None$ ,  $out=None$ )

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e.  $axis = None$ ).

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amin** : `coo_matrix` or scalar

Minimum of  $a$ . If  $axis$  is `None`, the result is a scalar value. If  $axis$  is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

**max** The maximum value of a sparse matrix along a given axis.

**`np.matrix.min`**

NumPy's implementation of 'min' for matrices

`csr_matrix.minimum` (*other*)

Element-wise minimum between this and another matrix.

`csr_matrix.multiply` (*other*)

Point-wise multiplication by another matrix, vector, or scalar.

`csr_matrix.nonzero()`  
 nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`csr_matrix.power(n, dtype=None)`  
 This function performs element-wise power.

**Parameters** **n** : n is a scalar  
**dtype** : If dtype is not specified, the current dtype will be preserved.

`csr_matrix.prune()`  
 Remove empty space after all non-zero elements.

`csr_matrix.rad2deg()`  
 Element-wise rad2deg.  
 See `numpy.rad2deg` for more information.

`csr_matrix.reshape(shape, order='C')`  
 Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints  
 The new shape should be compatible with the original shape.  
**order** : 'C', optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **reshaped\_matrix** : *self* with the new dimensions of *shape*

**See also:**

**`np.matrix.reshape`**  
 NumPy's implementation of 'reshape' for matrices

`csr_matrix.rint()`  
 Element-wise rint.  
 See `numpy.rint` for more information.

`csr_matrix.set_shape(shape)`  
 See `reshape`.

`csr_matrix.setdiag(values, k=0)`  
 Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : array\_like  
 New values of the diagonal elements.  
 Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.  
 If a scalar value is given, all of the diagonal is set to it.

**k** : int, optional  
 Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

`csr_matrix.sign()`  
Element-wise sign.

See `numpy.sign` for more information.

`csr_matrix.sin()`  
Element-wise sin.

See `numpy.sin` for more information.

`csr_matrix.sinh()`  
Element-wise sinh.

See `numpy.sinh` for more information.

`csr_matrix.sort_indices()`  
Sort the indices of this matrix *in place*

`csr_matrix.sorted_indices()`  
Return a copy of this matrix with sorted indices

`csr_matrix.sqrt()`  
Element-wise sqrt.

See `numpy.sqrt` for more information.

`csr_matrix.sum(axis=None, dtype=None, out=None)`  
Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).

**dtype** : dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **sum\_along\_axis** : np.matrix

A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

**`np.matrix.sum`**

NumPy's implementation of 'sum' for matrices

`csr_matrix.sum_duplicates()`  
Eliminate duplicate matrix entries by adding them together

This is an *in place* operation

`csr_matrix.tan()`  
Element-wise tan.

See `numpy.tan` for more information.

`csr_matrix.tanh()`  
Element-wise tanh.

See `numpy.tanh` for more information.

`csr_matrix.toarray` (*order=None, out=None*)

Return a dense ndarray representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns** **arr** : ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

`csr_matrix.tobsr` (*blocksize=None, copy=True*)

Convert this matrix to Block Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When *blocksize=(R, C)* is provided, it will be used for construction of the `bsr_matrix`.

`csr_matrix.tocoo` (*copy=True*)

Convert this matrix to COOrdinate format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`csr_matrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`csr_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`csr_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns** **arr** : `numpy.matrix`, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory

order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`csr_matrix.todia` (*copy=False*)

Convert this matrix to sparse DIAgonal format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`csr_matrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`csr_matrix.tolil` (*copy=False*)

Convert this matrix to LInked List format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`csr_matrix.transpose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters** *axes* : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

*copy* : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns** *p* : *self* with the dimensions reversed.

**See also:**

`np.matrix.transpose`

NumPy's implementation of 'transpose' for matrices

`csr_matrix.trunc` ()

Element-wise trunc.

See `numpy.trunc` for more information.

**class** `scipy.sparse.dia_matrix` (*arg1, shape=None, dtype=None, copy=False*)

Sparse matrix with DIAgonal storage

*This can be instantiated in several ways:*

`dia_matrix(D)` with a dense matrix

`dia_matrix(S)` with another sparse matrix *S* (equivalent to `S.todia()`)

`dia_matrix((M, N), [dtype])`

to construct an empty matrix with shape (M, N), *dtype* is optional, defaulting to `dtype='d'`.

`dia_matrix((data, offsets), shape=(M, N))`

where the `data[k, :]` stores the diagonal entries for diagonal `offsets[k]` (See example below)

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import dia_matrix
>>> dia_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> data = np.array([[1, 2, 3, 4]]).repeat(3, axis=0)
>>> offsets = np.array([0, -1, 2])
>>> dia_matrix((data, offsets), shape=(4, 4)).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

**Attributes**

<i>shape</i>	Get shape of a matrix.
<i>nnz</i>	Number of stored values, including explicit zeros.

`dia_matrix.shape`  
Get shape of a matrix.

`dia_matrix.nnz`  
Number of stored values, including explicit zeros.

**See also:**

**count\_nonzero**  
Number of non-zero entries

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	DIA format data array of the matrix
<code>offsets</code>	DIA format offset array of the matrix

**Methods**

<i>arcsin()</i>	Element-wise arcsin.
<i>arcsinh()</i>	Element-wise arcsinh.
<i>arctan()</i>	Element-wise arctan.
<i>arctanh()</i>	Element-wise arctanh.
<i>asformat(format)</i>	Return this matrix in a given sparse format
<i>asfptype()</i>	Upcast matrix to a floating point format (if necessary)
<i>astype(dtype[, casting, copy])</i>	Cast the matrix elements to a specified type.
<i>ceil()</i>	Element-wise ceil.
<i>conj()</i>	Element-wise complex conjugation.
<i>conjugate()</i>	Element-wise complex conjugation.
<i>copy()</i>	Returns a copy of this matrix.
<i>count_nonzero()</i>	Number of non-zero entries, equivalent to
<i>deg2rad()</i>	Element-wise deg2rad.
<i>diagonal([k])</i>	Returns the k-th diagonal of the matrix.

Table 5.172 – continued from previous page

<code>dot(other)</code>	Ordinary dot product
<code>expm1()</code>	Element-wise <code>expm1</code> .
<code>floor()</code>	Element-wise floor.
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(j)</code>	Returns a copy of column <code>j</code> of the matrix, as an $(m \times 1)$ sparse matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row <code>i</code> of the matrix, as a $(1 \times n)$ sparse matrix (row vector).
<code>log1p()</code>	Element-wise <code>log1p</code> .
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	This function performs element-wise power.
<code>rad2deg()</code>	Element-wise <code>rad2deg</code> .
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>rint()</code>	Element-wise <code>rint</code> .
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sign()</code>	Element-wise <code>sign</code> .
<code>sin()</code>	Element-wise <code>sin</code> .
<code>sinh()</code>	Element-wise <code>sinh</code> .
<code>sqrt()</code>	Element-wise <code>sqrt</code> .
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>tan()</code>	Element-wise <code>tan</code> .
<code>tanh()</code>	Element-wise <code>tanh</code> .
<code>toarray([order, out])</code>	Return a dense ndarray representation of this matrix.
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise <code>trunc</code> .

`dia_matrix.arcsin()`  
Element-wise `arcsin`.

See `numpy.arcsin` for more information.

`dia_matrix.arcsinh()`  
Element-wise arcsinh.

See `numpy.arcsinh` for more information.

`dia_matrix.arctan()`  
Element-wise arctan.

See `numpy.arctan` for more information.

`dia_matrix.arctanh()`  
Element-wise arctanh.

See `numpy.arctanh` for more information.

`dia_matrix.asformat(format)`  
Return this matrix in a given sparse format

**Parameters** **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for `csr_matrix` format
- “csc” for `csc_matrix` format
- “lil” for `lil_matrix` format
- “dok” for `dok_matrix` format and so on

`dia_matrix.asfptype()`  
Upcast matrix to a floating point format (if necessary)

`dia_matrix.astype(dtype, casting='unsafe', copy=True)`  
Cast the matrix elements to a specified type.

**Parameters** **dtype** : string or numpy dtype  
Typecode or data-type to which to cast the data.

**casting** : {'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional  
Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same\_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

**copy** : bool, optional  
If `copy` is `False`, the result might share some memory with this matrix. If `copy` is `True`, it is guaranteed that the result and this matrix do not share any memory.

`dia_matrix.ceil()`  
Element-wise ceil.

See `numpy.ceil` for more information.

`dia_matrix.conj()`  
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`dia_matrix.conjugate()`  
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`dia_matrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`dia_matrix.count_nonzero()`

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`dia_matrix.deg2rad()`

Element-wise `deg2rad`.

See `numpy.deg2rad` for more information.

`dia_matrix.diagonal(k=0)`

Returns the *k*-th diagonal of the matrix.

**Parameters** *k* : int, optional

Which diagonal to set, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

**See also:**

[\*numpy.diagonal\*](#)

Equivalent numpy function.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

`dia_matrix.dot(other)`

Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`dia_matrix.expm1()`

Element-wise `expm1`.

See `numpy.expm1` for more information.

`dia_matrix.floor()`

Element-wise `floor`.

See `numpy.floor` for more information.

`dia_matrix.getH()`

Return the Hermitian transpose of this matrix.

**See also:**

**`np.matrix.getH`**

NumPy's implementation of `getH` for matrices

`dia_matrix.get_shape()`

Get shape of a matrix.

`dia_matrix.getcol(j)`

Returns a copy of column `j` of the matrix, as an  $(m \times 1)$  sparse matrix (column vector).

`dia_matrix.getformat()`

Format of a matrix representation as a string.

`dia_matrix.getmaxprint()`

Maximum number of elements to display when printed.

`dia_matrix.getnnz(axis=None)`

Number of stored values, including explicit zeros.

**Parameters** **axis** : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

**`count_nonzero`**

Number of non-zero entries

`dia_matrix.getrow(i)`

Returns a copy of row `i` of the matrix, as a  $(1 \times n)$  sparse matrix (row vector).

`dia_matrix.log1p()`

Element-wise `log1p`.

See `numpy.log1p` for more information.

`dia_matrix.maximum(other)`

Element-wise maximum between this and another matrix.

`dia_matrix.mean(axis=None, dtype=None, out=None)`

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters** **axis** :  $\{-2, -1, 0, 1, \text{None}\}$  optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. `axis = None`).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.

**out** : `np.matrix`, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : `np.matrix`

**See also:**

**np.matrix.mean**

NumPy's implementation of 'mean' for matrices

`dia_matrix.minimum (other)`

Element-wise minimum between this and another matrix.

`dia_matrix.multiply (other)`

Point-wise multiplication by another matrix

`dia_matrix.nonzero ()`

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`dia_matrix.power (n, dtype=None)`

This function performs element-wise power.

**Parameters****n** : n is a scalar**dtype** : If dtype is not specified, the current dtype will be preserved.`dia_matrix.rad2deg ()`

Element-wise rad2deg.

See `numpy.rad2deg` for more information.`dia_matrix.reshape (shape, order='C')`

Gives a new shape to a sparse matrix without changing its data.

**Parameters****shape** : length-2 tuple of ints

The new shape should be compatible with the original shape.

**order** : 'C', optionalThis argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.**Returns****reshaped\_matrix** : *self* with the new dimensions of *shape***See also:****np.matrix.reshape**

NumPy's implementation of 'reshape' for matrices

`dia_matrix.rint ()`

Element-wise rint.

See `numpy.rint` for more information.`dia_matrix.set_shape (shape)`See `reshape`.`dia_matrix.setdiag (values, k=0)`

Set diagonal or off-diagonal elements of the array.

**Parameters****values** : array\_like

New values of the diagonal elements.

Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored. If a scalar value is given, all of the diagonal is set to it.

**k** : int, optional

Which off-diagonal to set, corresponding to elements  $a[i,i+k]$ . Default: 0 (the main diagonal).

`dia_matrix.sign()`

Element-wise sign.

See `numpy.sign` for more information.

`dia_matrix.sin()`

Element-wise sin.

See `numpy.sin` for more information.

`dia_matrix.sinh()`

Element-wise sinh.

See `numpy.sinh` for more information.

`dia_matrix.sqrt()`

Element-wise sqrt.

See `numpy.sqrt` for more information.

`dia_matrix.sum(axis=None, dtype=None, out=None)`

Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).

**dtype** : dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **sum\_along\_axis** : np.matrix

A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

**`np.matrix.sum`**

NumPy's implementation of 'sum' for matrices

`dia_matrix.tan()`

Element-wise tan.

See `numpy.tan` for more information.

`dia_matrix.tanh()`

Element-wise tanh.

See `numpy.tanh` for more information.

`dia_matrix.toarray` (*order=None, out=None*)

Return a dense ndarray representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns** **arr** : ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

`dia_matrix.tobsr` (*blocksize=None, copy=False*)

Convert this matrix to Block Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When *blocksize=(R, C)* is provided, it will be used for construction of the `bsr_matrix`.

`dia_matrix.tocoo` (*copy=False*)

Convert this matrix to COOrdinate format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`dia_matrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`dia_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`dia_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns** **arr** : `numpy.matrix`, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`dia_matrix.todia (copy=False)`

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`dia_matrix.todok (copy=False)`

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`dia_matrix.tolil (copy=False)`

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`dia_matrix.transpose (axes=None, copy=False)`

Reverses the dimensions of the sparse matrix.

**Parameters** `axes` : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

`copy` : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns** `p` : *self* with the dimensions reversed.

**See also:**

`np.matrix.transpose`

NumPy's implementation of 'transpose' for matrices

`dia_matrix.trunc ()`

Element-wise trunc.

See `numpy.trunc` for more information.

**class** `scipy.sparse.dok_matrix (arg1, shape=None, dtype=None, copy=False)`

Dictionary Of Keys based sparse matrix.

This is an efficient structure for constructing sparse matrices incrementally.

*This can be instantiated in several ways:*

`dok_matrix(D)`

with a dense matrix, D

`dok_matrix(S)` with a sparse matrix, S

`dok_matrix((M,N), [dtype])`

create the matrix with initial shape (M,N) dtype is optional, defaulting to dtype='d'

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Allows for efficient O(1) access of individual elements. Duplicates are not allowed. Can be efficiently converted to a `coo_matrix` once constructed.

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import dok_matrix
```

```
>>> S = dok_matrix((5, 5), dtype=np.float32)
>>> for i in range(5):
...     for j in range(5):
...         S[i, j] = i + j      # Update element
```

**Attributes**

<i>shape</i>	Get shape of a matrix.
<i>nnz</i>	Number of stored values, including explicit zeros.

`dok_matrix.shape`  
Get shape of a matrix.

`dok_matrix.nnz`  
Number of stored values, including explicit zeros.

**See also:**

**count\_nonzero**  
Number of non-zero entries

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)

**Methods**

<i>asformat(format)</i>	Return this matrix in a given sparse format
<i>asfptype()</i>	Upcast matrix to a floating point format (if necessary)
<i>astype(dtype[, casting, copy])</i>	Cast the matrix elements to a specified type.
<i>clear()</i> -> None. Remove all items from D.)	
<i>conj()</i>	Element-wise complex conjugation.
<i>conjtransp()</i>	Return the conjugate transpose.
<i>conjugate()</i>	Element-wise complex conjugation.
<i>copy()</i>	Returns a copy of this matrix.
<i>count_nonzero()</i>	Number of non-zero entries, equivalent to
<i>diagonal([k])</i>	Returns the k-th diagonal of the matrix.
<i>dot(other)</i>	Ordinary dot product
<i>fromkeys(...)</i>	v defaults to None.
<i>get(key[, default])</i>	This overrides the dict.get method, providing type checking but otherwise equivalent functionality.
<i>getH()</i>	Return the Hermitian transpose of this matrix.
<i>get_shape()</i>	Get shape of a matrix.
<i>getcol(j)</i>	Returns the j-th column as a (m x 1) DOK matrix.
<i>getformat()</i>	Format of a matrix representation as a string.
<i>getmaxprint()</i>	Maximum number of elements to display when printed.
<i>getnnz([axis])</i>	Number of stored values, including explicit zeros.
<i>getrow(i)</i>	Returns the i-th row as a (1 x n) DOK matrix.
<i>has_key(k)</i> -> True if D has a key k, else False)	
<i>items()</i> -> list of D's (key, value) pairs, ...)	
<i>iteritems()</i> -> an iterator over the (key, ...)	
<i>iterkeys()</i> -> an iterator over the keys of D)	
<i>itervalues(...)</i>	
<i>keys()</i> -> list of D's keys)	

Continued on next page

Table 5.174 – continued from previous page

<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix
<code>nonzero()</code>	nonzero indices
<code>pop((k[,d]) -&gt; v, ...)</code>	If key is not found, d is returned if given, otherwise KeyError is raised
<code>popitem() -&gt; (k, v), ...)</code>	2-tuple; but raise KeyError if D is empty.
<code>power(n[, dtype])</code>	Element-wise power.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>resize(shape)</code>	Resize the matrix in-place to dimensions given by <i>shape</i> .
<code>set_shape(shape)</code>	See <i>reshape</i> .
<code>setdefault((k[,d]) -&gt; D.get(k,d), ...)</code>	
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>toarray([order, out])</code>	Return a dense ndarray representation of this matrix.
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LIInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>update(val)</code>	
<code>values() -&gt; list of D's values)</code>	
<code>viewitems(...)</code>	
<code>viewkeys(...)</code>	
<code>viewvalues(...)</code>	

`dok_matrix.asformat` (*format*)

Return this matrix in a given sparse format

**Parameters** **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for csr\_matrix format
- “csc” for csc\_matrix format
- “lil” for lil\_matrix format
- “dok” for dok\_matrix format and so on

`dok_matrix.asfptype` ()

Upcast matrix to a floating point format (if necessary)

`dok_matrix.astype` (*dtype, casting='unsafe', copy=True*)

Cast the matrix elements to a specified type.

**Parameters**

- dtype** : string or numpy dtype  
Typecode or data-type to which to cast the data.
- casting** : {'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional  
Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same\_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.
- copy** : bool, optional  
If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

`dok_matrix.clear()` → None. Remove all items from D.

`dok_matrix.conj()`  
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`dok_matrix.conjtransp()`  
Return the conjugate transpose.

`dok_matrix.conjugate()`  
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`dok_matrix.copy()`  
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`dok_matrix.count_nonzero()`  
Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`dok_matrix.diagonal(k=0)`  
Returns the k-th diagonal of the matrix.

**Parameters**

- k** : int, optional  
Which diagonal to set, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

**See also:**

[\*numpy.diagonal\*](#)  
Equivalent numpy function.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
```

```
>>> A.diagonal(k=1)
array([2, 3])
```

`dok_matrix.dot` (*other*)  
 Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`dok_matrix.fromkeys` (*S*[, *v*]) → New dict with keys from *S* and values equal to *v*.  
*v* defaults to None.

`dok_matrix.get` (*key*, *default=0.0*)  
 This overrides the dict.get method, providing type checking but otherwise equivalent functionality.

`dok_matrix.getH` ()  
 Return the Hermitian transpose of this matrix.

**See also:**

**`np.matrix.getH`**  
 NumPy's implementation of *getH* for matrices

`dok_matrix.get_shape` ()  
 Get shape of a matrix.

`dok_matrix.getcol` (*j*)  
 Returns the *j*-th column as a (m x 1) DOK matrix.

`dok_matrix.getformat` ()  
 Format of a matrix representation as a string.

`dok_matrix.getmaxprint` ()  
 Maximum number of elements to display when printed.

`dok_matrix.getnnz` (*axis=None*)  
 Number of stored values, including explicit zeros.

**Parameters** **axis** : None, 0, or 1  
 Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

**`count_nonzero`**  
 Number of non-zero entries

`dok_matrix.getrow` (*i*)  
 Returns the *i*-th row as a (1 x n) DOK matrix.

`dok_matrix.has_key` (*k*) → True if *D* has a key *k*, else False

`dok_matrix.items` () → list of *D*'s (key, value) pairs, as 2-tuples

`dok_matrix.iteritems()` → an iterator over the (key, value) items of D

`dok_matrix.iterkeys()` → an iterator over the keys of D

`dok_matrix.itervalues()` → an iterator over the values of D

`dok_matrix.keys()` → list of D's keys

`dok_matrix.maximum(other)`

Element-wise maximum between this and another matrix.

`dok_matrix.mean(axis=None, dtype=None, out=None)`

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

**`np.matrix.mean`**

NumPy's implementation of 'mean' for matrices

`dok_matrix.minimum(other)`

Element-wise minimum between this and another matrix.

`dok_matrix.multiply(other)`

Point-wise multiplication by another matrix

`dok_matrix.nonzero()`

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`dok_matrix.pop(k[, d])` → v, remove specified key and return the corresponding value.

If key is not found, d is returned if given, otherwise `KeyError` is raised

`dok_matrix.popitem()` → (k, v), remove and return some (key, value) pair as a

2-tuple; but raise `KeyError` if D is empty.

`dok_matrix.power` (*n*, *dtype=None*)

Element-wise power.

`dok_matrix.reshape` (*shape*, *order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints

The new shape should be compatible with the original shape.

**order** : 'C', optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this

**Returns** **reshaped\_matrix** : *self* with the new dimensions of *shape*

**See also:**

**`np.matrix.reshape`**

NumPy's implementation of 'reshape' for matrices

`dok_matrix.resize` (*shape*)

Resize the matrix in-place to dimensions given by *shape*.

Any non-zero elements that lie outside the new shape are removed.

`dok_matrix.set_shape` (*shape*)

See *reshape*.

`dok_matrix.setdefault` (*k*[, *d*]) → *D.get(k,d)*, also set *D[k]=d* if *k* not in *D*

`dok_matrix.setdiag` (*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : array\_like

New values of the diagonal elements.

Values may have any length. If the diagonal is longer than *values*, then the remaining diagonal entries will not be set. If *values* is longer than the diagonal, then the remaining *values* are ignored.

If a scalar value is given, all of the diagonal is set to it.

**k** : int, optional

Which off-diagonal to set, corresponding to elements *a[i,i+k]*. Default: 0 (the main diagonal).

`dok_matrix.sum` (*axis=None*, *dtype=None*, *out=None*)

Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).

**dtype** : dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output

**Returns** **sum\_along\_axis** : np.matrix

A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

**`np.matrix.sum`**

NumPy's implementation of 'sum' for matrices

`dok_matrix.toarray` (*order=None, out=None*)

Return a dense ndarray representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns** **arr** : ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

`dok_matrix.tobsr` (*blocksize=None, copy=False*)

Convert this matrix to Block Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When *blocksize=(R, C)* is provided, it will be used for construction of the `bsr_matrix`.

`dok_matrix.tocoo` (*copy=False*)

Convert this matrix to COOrdinate format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`dok_matrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`dok_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`dok_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**     **arr** : numpy.matrix, 2-dimensional  
 A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`dok_matrix.todia (copy=False)`  
 Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`dok_matrix.todok (copy=False)`  
 Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`dok_matrix.tolil (copy=False)`  
 Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`dok_matrix.transpose (axes=None, copy=False)`  
 Reverses the dimensions of the sparse matrix.

**Parameters**   **axes** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional  
 Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**     **p** : *self* with the dimensions reversed.

**See also:**

**`np.matrix.transpose`**  
 NumPy's implementation of 'transpose' for matrices

`dok_matrix.update (val)`

`dok_matrix.values ()` → list of D's values

`dok_matrix.viewitems ()` → a set-like object providing a view on D's items

`dok_matrix.viewkeys ()` → a set-like object providing a view on D's keys

`dok_matrix.viewvalues ()` → an object providing a view on D's values

**class** `scipy.sparse.lil_matrix (arg1, shape=None, dtype=None, copy=False)`  
 Row-based linked list sparse matrix

This is a structure for constructing sparse matrices incrementally. Note that inserting a single item can take linear time in the worst case; to construct a matrix efficiently, make sure the items are pre-sorted by index, per row.

*This can be instantiated in several ways:*

`lil_matrix(D)` with a dense matrix or rank-2 ndarray D

`lil_matrix(S)` with another sparse matrix S (equivalent to `S.tolil()`)  
`lil_matrix((M, N), [dtype])`  
to construct an empty matrix with shape (M, N) dtype is optional, defaulting to `dtype='d'`.

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

**Advantages of the LIL format**

- supports flexible slicing
- changes to the matrix sparsity structure are efficient

**Disadvantages of the LIL format**

- arithmetic operations LIL + LIL are slow (consider CSR or CSC)
- slow column slicing (consider CSC)
- slow matrix vector products (consider CSR or CSC)

**Intended Usage**

- LIL is a convenient format for constructing sparse matrices
- once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
- consider using the COO format when constructing large matrices

**Data Structure**

- An array (`self.rows`) of rows, each of which is a sorted list of column indices of non-zero elements.
- The corresponding nonzero values are stored in similar fashion in `self.data`.

**Attributes**

<code>shape</code>	Get shape of a matrix.
<code>nnz</code>	Number of stored values, including explicit zeros.

`lil_matrix.shape`  
Get shape of a matrix.

`lil_matrix.nnz`  
Number of stored values, including explicit zeros.

**See also:**

`count_nonzero`  
Number of non-zero entries

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	LIL format data array of the matrix
<code>rows</code>	LIL format row index array of the matrix

**Methods**

<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)

Continued on next page

Table 5.176 – continued from previous page

<code>astype(dtype[, casting, copy])</code>	Cast the matrix elements to a specified type.
<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>diagonal([k])</code>	Returns the k-th diagonal of the matrix.
<code>dot(other)</code>	Ordinary dot product
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(j)</code>	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of the ‘i’th row.
<code>getrowview(i)</code>	Returns a view of the ‘i’th row (without copying).
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	Element-wise power.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>set_shape(shape)</code>	See <i>reshape</i> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>toarray([order, out])</code>	Return a dense ndarray representation of this matrix.
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.

`lil_matrix.asformat(format)`

Return this matrix in a given sparse format

**Parameters** `format` : {string, None}

*desired sparse matrix format*

- None for no format conversion
- “csr” for `csr_matrix` format
- “csc” for `csc_matrix` format
- “lil” for `lil_matrix` format
- “dok” for `dok_matrix` format and so on

`lil_matrix.astype()`

Upcast matrix to a floating point format (if necessary)

`lil_matrix.astype(dtype, casting='unsafe', copy=True)`

Cast the matrix elements to a specified type.

**Parameters** `dtype` : string or numpy dtype

Typecode or data-type to which to cast the data.

`casting` : {'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional

Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same\_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

`copy` : bool, optional

If `copy` is *False*, the result might share some memory with this matrix. If `copy` is *True*, it is guaranteed that the result and this matrix do not share any memory.

`lil_matrix.conj()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`lil_matrix.conjugate()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`lil_matrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`lil_matrix.count_nonzero()`

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`lil_matrix.diagonal(k=0)`

Returns the k-th diagonal of the matrix.

**Parameters** `k` : int, optional

Which diagonal to set, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

**See also:**

[\*numpy.diagonal\*](#)

Equivalent numpy function.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
```

```
>>> A.diagonal(k=1)
array([2, 3])
```

`lil_matrix.dot` (*other*)  
 Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`lil_matrix.getH` ()  
 Return the Hermitian transpose of this matrix.

**See also:**

`np.matrix.getH`  
 NumPy's implementation of *getH* for matrices

`lil_matrix.get_shape` ()  
 Get shape of a matrix.

`lil_matrix.getcol` (*j*)  
 Returns a copy of column *j* of the matrix, as an (*m* x 1) sparse matrix (column vector).

`lil_matrix.getformat` ()  
 Format of a matrix representation as a string.

`lil_matrix.getmaxprint` ()  
 Maximum number of elements to display when printed.

`lil_matrix.getnnz` (*axis=None*)  
 Number of stored values, including explicit zeros.

**Parameters** `axis` : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

`count_nonzero`  
 Number of non-zero entries

`lil_matrix.getrow` (*i*)  
 Returns a copy of the '*i*'th row.

`lil_matrix.getrowview` (*i*)  
 Returns a view of the '*i*'th row (without copying).

`lil_matrix.maximum` (*other*)  
 Element-wise maximum between this and another matrix.

`lil_matrix.mean` (*axis=None, dtype=None, out=None*)  
 Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters**

- axis** : {-2, -1, 0, 1, None} optional  
Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).
- dtype** : data-type, optional  
Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
- out** : np.matrix, optional  
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

**`np.matrix.mean`**

NumPy's implementation of 'mean' for matrices

`lil_matrix.minimum` (*other*)

Element-wise minimum between this and another matrix.

`lil_matrix.multiply` (*other*)

Point-wise multiplication by another matrix

`lil_matrix.nonzero` ()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`lil_matrix.power` (*n*, *dtype=None*)

Element-wise power.

`lil_matrix.reshape` (*shape*, *order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints

The new shape should be compatible with the original shape.

**order** : 'C', optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **reshaped\_matrix** : *self* with the new dimensions of *shape*

**See also:**

**`np.matrix.reshape`**

NumPy's implementation of 'reshape' for matrices

`lil_matrix.set_shape` (*shape*)

See *reshape*.

`lil_matrix.setdiag` (*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : array\_like

New values of the diagonal elements.

Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.

If a scalar value is given, all of the diagonal is set to it.

**k** : int, optional

Which off-diagonal to set, corresponding to elements  $a[i,i+k]$ . Default: 0 (the main diagonal).

`lil_matrix.sum` (*axis=None, dtype=None, out=None*)

Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).

**dtype** : dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **sum\_along\_axis** : np.matrix

A matrix with the same shape as *self*, with the specified axis removed.

See also:

`np.matrix.sum`

NumPy's implementation of 'sum' for matrices

`lil_matrix.toarray` (*order=None, out=None*)

Return a dense ndarray representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns** **arr** : ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

`lil_matrix.tobsr` (*blocksize=None, copy=False*)

Convert this matrix to Block Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

`lil_matrix.tocoo` (*copy=False*)

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`lil_matrix.tocsf` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`lil_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`lil_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters**    **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**        **arr** : numpy.matrix, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`lil_matrix.todia` (*copy=False*)

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`lil_matrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`lil_matrix.tolil` (*copy=False*)

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`lil_matrix.transpose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters**    **axes** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending

**Returns**        **p** : *self* with the dimensions reversed.

See also:

**`np.matrix.transpose`**

NumPy's implementation of 'transpose' for matrices

**class** `scipy.sparse.spmatrix` (*maxprint=50*)

This class provides a base class for all sparse matrices. It cannot be instantiated. Most of the work is provided by subclasses.

**Attributes**

<code>nnz</code>	Number of stored values, including explicit zeros.
<code>shape</code>	Get shape of a matrix.

`spmatrix.nnz`

Number of stored values, including explicit zeros.

See also:

**`count_nonzero`**

Number of non-zero entries

`spmatrix.shape`

Get shape of a matrix.

**Methods**

<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(dtype[, casting, copy])</code>	Cast the matrix elements to a specified type.
<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>diagonal([k])</code>	Returns the k-th diagonal of the matrix.
<code>dot(other)</code>	Ordinary dot product
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(j)</code>	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	Element-wise power.

Continued on next page

Table 5.178 – continued from previous page

<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>toarray([order, out])</code>	Return a dense ndarray representation of this matrix.
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.

`spmatrix.asformat` (*format*)

Return this matrix in a given sparse format

**Parameters** `format` : {string, None}

*desired sparse matrix format*

- None for no format conversion
- “csr” for `csr_matrix` format
- “csc” for `csc_matrix` format
- “lil” for `lil_matrix` format
- “dok” for `dok_matrix` format and so on

`spmatrix.asfptype` ()

Upcast matrix to a floating point format (if necessary)

`spmatrix.astype` (*dtype*, *casting*='unsafe', *copy*=True)

Cast the matrix elements to a specified type.

**Parameters** `dtype` : string or numpy dtype

Typecode or data-type to which to cast the data.

**casting** : {'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional

Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same\_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

**copy** : bool, optional

If `copy` is *False*, the result might share some memory with this matrix. If `copy` is *True*, it is guaranteed that the result and this matrix do not share any memory.

`spmatrix.conj` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`spmatrix.conjugate()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`spmatrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`spmatrix.count_nonzero()`

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`spmatrix.diagonal(k=0)`

Returns the k-th diagonal of the matrix.

**Parameters** `k` : int, optional

Which diagonal to set, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

**See also:**

[\*numpy.diagonal\*](#)

Equivalent numpy function.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

`spmatrix.dot(other)`

Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`spmatrix.getH()`

Return the Hermitian transpose of this matrix.

**See also:**

[\*np.matrix.getH\*](#)

NumPy's implementation of `getH` for matrices

`spmatrix.get_shape()`

Get shape of a matrix.

`spmatrix.getcol(j)`

Returns a copy of column *j* of the matrix, as an (*m* x 1) sparse matrix (column vector).

`spmatrix.getformat()`

Format of a matrix representation as a string.

`spmatrix.getmaxprint()`

Maximum number of elements to display when printed.

`spmatrix.getnnz(axis=None)`

Number of stored values, including explicit zeros.

**Parameters** **axis** : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

**count\_nonzero**

Number of non-zero entries

`spmatrix.getrow(i)`

Returns a copy of row *i* of the matrix, as a (1 x *n*) sparse matrix (row vector).

`spmatrix.maximum(other)`

Element-wise maximum between this and another matrix.

`spmatrix.mean(axis=None, dtype=None, out=None)`

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

**np.matrix.mean**

NumPy's implementation of 'mean' for matrices

`spmatrix.minimum(other)`

Element-wise minimum between this and another matrix.

`spmatrix.multiply(other)`

Point-wise multiplication by another matrix

`spmatrix.nonzero()`

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

**`np.matrix.sum`**

NumPy's implementation of 'sum' for matrices

`spmatrix.toarray` (*order=None, out=None*)

Return a dense ndarray representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns** **arr** : ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

`spmatrix.tobsr` (*blocksize=None, copy=False*)

Convert this matrix to Block Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When *blocksize=(R, C)* is provided, it will be used for construction of the `bsr_matrix`.

`spmatrix.tocoo` (*copy=False*)

Convert this matrix to COOrdinate format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`spmatrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`spmatrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`spmatrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**     **arr** : `numpy.matrix`, 2-dimensional  
 A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`spmatrix.todia` (*copy=False*)  
 Convert this matrix to sparse DIAgonal format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`spmatrix.todok` (*copy=False*)  
 Convert this matrix to Dictionary Of Keys format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`spmatrix.tolil` (*copy=False*)  
 Convert this matrix to LInked List format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`spmatrix.transpose` (*axes=None, copy=False*)  
 Reverses the dimensions of the sparse matrix.

**Parameters**   **axes** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional  
 Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**     **p** : *self* with the dimensions reversed.

**See also:**

**`np.matrix.transpose`**  
 NumPy's implementation of 'transpose' for matrices

## Functions

Building sparse matrices:

<code>eye(m[, n, k, dtype, format])</code>	Sparse matrix with ones on diagonal
<code>identity(n[, dtype, format])</code>	Identity matrix in sparse format
<code>kron(A, B[, format])</code>	kronecker product of sparse matrices A and B
<code>kronsum(A, B[, format])</code>	kronecker sum of sparse matrices A and B
<code>diags(diagonals[, offsets, shape, format, dtype])</code>	Construct a sparse matrix from diagonals.
<code>spdiags(data, diags, m, n[, format])</code>	Return a sparse matrix from diagonals.
<code>block_diag(mats[, format, dtype])</code>	Build a block diagonal sparse matrix from provided matrices.
<code>tril(A[, k, format])</code>	Return the lower triangular portion of a matrix in sparse format
<code>triu(A[, k, format])</code>	Return the upper triangular portion of a matrix in sparse format
<code>bmat(blocks[, format, dtype])</code>	Build a sparse matrix from sparse sub-blocks
<code>hstack(blocks[, format, dtype])</code>	Stack sparse matrices horizontally (column wise)

Continued on next page

Table 5.179 – continued from previous page

<code>vstack(blocks[, format, dtype])</code>	Stack sparse matrices vertically (row wise)
<code>rand(m, n[, density, format, dtype, ...])</code>	Generate a sparse matrix of the given shape and density with uniformly distributed values.
<code>random(m, n[, density, format, dtype, ...])</code>	Generate a sparse matrix of the given shape and density with randomly distributed values.

`scipy.sparse.eye(m, n=None, k=0, dtype=<type 'float'>, format=None)`

Sparse matrix with ones on diagonal

Returns a sparse (m x n) matrix where the k-th diagonal is all ones and everything else is zeros.

**Parameters**

- m** : int  
Number of rows in the matrix.
- n** : int, optional  
Number of columns. Default: *m*.
- k** : int, optional  
Diagonal to place ones on. Default: 0 (main diagonal).
- dtype** : dtype, optional  
Data type of the matrix.
- format** : str, optional  
Sparse format of the result, e.g. format="csr", etc.

### Examples

```
>>> from scipy import sparse
>>> sparse.eye(3).toarray()
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> sparse.eye(3, dtype=np.int8)
<3x3 sparse matrix of type '<class 'numpy.int8'>'
with 3 stored elements (1 diagonals) in DIAgonal format>
```

`scipy.sparse.identity(n, dtype='d', format=None)`

Identity matrix in sparse format

Returns an identity matrix with shape (n,n) using a given sparse format and dtype.

**Parameters**

- n** : int  
Shape of the identity matrix.
- dtype** : dtype, optional  
Data type of the matrix
- format** : str, optional  
Sparse format of the result, e.g. format="csr", etc.

### Examples

```
>>> from scipy.sparse import identity
>>> identity(3).toarray()
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> identity(3, dtype='int8', format='dia')
<3x3 sparse matrix of type '<class 'numpy.int8'>'
with 3 stored elements (1 diagonals) in DIAgonal format>
```

`scipy.sparse.kron(A, B, format=None)`  
 kronecker product of sparse matrices A and B

**Parameters**

- A** : sparse or dense matrix  
first matrix of the product
- B** : sparse or dense matrix  
second matrix of the product
- format** : str, optional  
format of the result (e.g. "csr")

**Returns** kronecker product in a sparse matrix format

**Examples**

```
>>> from scipy import sparse
>>> A = sparse.csr_matrix(np.array([[0, 2], [5, 0]]))
>>> B = sparse.csr_matrix(np.array([[1, 2], [3, 4]]))
>>> sparse.kron(A, B).toarray()
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])
```

```
>>> sparse.kron(A, [[1, 2], [3, 4]].toarray())
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])
```

`scipy.sparse.kronsum(A, B, format=None)`  
 kronecker sum of sparse matrices A and B

Kronecker sum of two sparse matrices is a sum of two Kronecker products  $\text{kron}(I_n, A) + \text{kron}(B, I_m)$  where A has shape (m,m) and B has shape (n,n) and  $I_m$  and  $I_n$  are identity matrices of shape (m,m) and (n,n) respectively.

**Parameters**

- A** : square matrix
- B** : square matrix
- format** : str  
format of the result (e.g. "csr")

**Returns** kronecker sum in a sparse matrix format

`scipy.sparse.diags(diagonals, offsets=0, shape=None, format=None, dtype=None)`  
 Construct a sparse matrix from diagonals.

**Parameters**

- diagonals** : sequence of array\_like  
Sequence of arrays containing the matrix diagonals, corresponding to *offsets*.
- offsets** : sequence of int or an int, optional  
**Diagonals to set:**
  - k = 0 the main diagonal (default)
  - k > 0 the k-th upper diagonal
  - k < 0 the k-th lower diagonal
- shape** : tuple of int, optional  
Shape of the result. If omitted, a square matrix large enough to contain the diagonals is returned.

**format** : {"dia", "csr", "csc", "lil", ...}, optional  
 Matrix format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.

**dtype** : dtype, optional  
 Data type of the matrix.

**See also:**

**spdiags** construct matrix from diagonals

**Notes**

This function differs from *spdiags* in the way it handles off-diagonals.

The result from *diags* is the sparse equivalent of:

```
np.diag(diagonals[0], offsets[0])
+ ...
+ np.diag(diagonals[k], offsets[k])
```

Repeated diagonal offsets are disallowed.

New in version 0.11.

**Examples**

```
>>> from scipy.sparse import diags
>>> diagonals = [[1, 2, 3, 4], [1, 2, 3], [1, 2]]
>>> diags(diagonals, [0, -1, 2]).toarray()
array([[1, 0, 1, 0],
       [1, 2, 0, 2],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

Broadcasting of scalars is supported (but shape needs to be specified):

```
>>> diags([1, -2, 1], [-1, 0, 1], shape=(4, 4)).toarray()
array([[ -2.,  1.,  0.,  0.],
       [  1., -2.,  1.,  0.],
       [  0.,  1., -2.,  1.],
       [  0.,  0.,  1., -2.]])
```

If only one diagonal is wanted (as in `numpy.diag`), the following works as well:

```
>>> diags([1, 2, 3], 1).toarray()
array([[ 0.,  1.,  0.,  0.],
       [ 0.,  0.,  2.,  0.],
       [ 0.,  0.,  0.,  3.],
       [ 0.,  0.,  0.,  0.]])
```

`scipy.sparse.spdiags` (*data*, *diags*, *m*, *n*, *format=None*)

Return a sparse matrix from diagonals.

**Parameters**

- data** : array\_like  
matrix diagonals stored row-wise
- diags** : diagonals to set
  - $k = 0$  the main diagonal
  - $k > 0$  the  $k$ -th upper diagonal
  - $k < 0$  the  $k$ -th lower diagonal
- m, n** : int  
shape of the result

**format** : str, optional

Format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.

**See also:**

**diags** more convenient form of this function

**dia\_matrix** the sparse DIAgonal format.

**Examples**

```
>>> from scipy.sparse import spdiags
>>> data = np.array([[1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4]])
>>> diags = np.array([0, -1, 2])
>>> spdiags(data, diags, 4, 4).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

`scipy.sparse.block_diag(mats, format=None, dtype=None)`

Build a block diagonal sparse matrix from provided matrices.

**Parameters** **mats** : sequence of matrices

Input matrices.

**format** : str, optional

The sparse format of the result (e.g. “csr”). If not given, the matrix is returned in “coo” format.

**dtype** : dtype specifier, optional

The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**Returns** **res** : sparse matrix

**See also:**

*bmat, diags*

**Notes**

New in version 0.11.0.

**Examples**

```
>>> from scipy.sparse import coo_matrix, block_diag
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> block_diag((A, B, C)).toarray()
array([[1, 2, 0, 0],
       [3, 4, 0, 0],
       [0, 0, 5, 0],
       [0, 0, 6, 0],
       [0, 0, 0, 7]])
```

`scipy.sparse.tril(A, k=0, format=None)`

Return the lower triangular portion of a matrix in sparse format

**Returns the elements on or below the *k*-th diagonal of the matrix *A*.**

- *k* = 0 corresponds to the main diagonal
- *k* > 0 is above the main diagonal

- $k < 0$  is below the main diagonal

**Parameters** **A** : dense or sparse matrix  
Matrix whose lower triangular portion is desired.

**k** : integer  
The top-most diagonal of the lower triangle.

**format** : string  
Sparse format of the result, e.g. format="csr", etc.

**Returns** **L** : sparse matrix  
Lower triangular portion of A in sparse format.

**See also:**

**triu** upper triangle in sparse format

**Examples**

```
>>> from scipy.sparse import csr_matrix, tril
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
...               dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> tril(A).toarray()
array([[1, 0, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 0, 0]])
>>> tril(A).nnz
4
>>> tril(A, k=1).toarray()
array([[1, 2, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 9, 0]])
>>> tril(A, k=-1).toarray()
array([[0, 0, 0, 0, 0],
       [4, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])
>>> tril(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
with 4 stored elements in Compressed Sparse Column format>
```

`scipy.sparse.triu(A, k=0, format=None)`

Return the upper triangular portion of a matrix in sparse format

**Returns the elements on or above the  $k$ -th diagonal of the matrix A.**

- $k = 0$  corresponds to the main diagonal
- $k > 0$  is above the main diagonal
- $k < 0$  is below the main diagonal

**Parameters** **A** : dense or sparse matrix  
Matrix whose upper triangular portion is desired.

**k** : integer  
The bottom-most diagonal of the upper triangle.

**format** : string  
Sparse format of the result, e.g. format="csr", etc.

**Returns** **L** : sparse matrix  
Upper triangular portion of A in sparse format.

**See also:****tril** lower triangle in sparse format**Examples**

```

>>> from scipy.sparse import csr_matrix, triu
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
...               dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).toarray()
array([[1, 2, 0, 0, 3],
       [0, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).nnz
8
>>> triu(A, k=1).toarray()
array([[0, 2, 0, 0, 3],
       [0, 0, 0, 6, 7],
       [0, 0, 0, 9, 0]])
>>> triu(A, k=-1).toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
  with 8 stored elements in Compressed Sparse Column format>

```

`scipy.sparse.bmat` (*blocks, format=None, dtype=None*)

Build a sparse matrix from sparse sub-blocks

**Parameters** **blocks** : array\_like

Grid of sparse matrices with compatible shapes. An entry of None implies an all-zero matrix.

**format** : {'bsr', 'coo', 'csc', 'csr', 'dia', 'dok', 'lil'}, optional

The sparse format of the result (e.g. "csr"). By default an appropriate sparse matrix format is returned. This choice is subject to change.

**dtype** : dtype, optional

The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**Returns** **bmat** : sparse matrix

**See also:***block\_diag, diags***Examples**

```

>>> from scipy.sparse import coo_matrix, bmat
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> bmat([[A, B], [None, C]]).toarray()
array([[1, 2, 5],
       [3, 4, 6],
       [0, 0, 7]])

```

```
>>> bmat([[A, None], [None, C]].toarray()
array([[1, 2, 0],
       [3, 4, 0],
       [0, 0, 7]])
```

`scipy.sparse.hstack` (*blocks, format=None, dtype=None*)

Stack sparse matrices horizontally (column wise)

**Parameters** **blocks**

sequence of sparse matrices with compatible shapes

**format** : str

sparse format of the result (e.g. “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.

**dtype** : dtype, optional

The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**See also:**

**vstack** stack sparse matrices vertically (row wise)

**Examples**

```
>>> from scipy.sparse import coo_matrix,.hstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>>.hstack([A,B]).toarray()
array([[1, 2, 5],
       [3, 4, 6]])
```

`scipy.sparse.vstack` (*blocks, format=None, dtype=None*)

Stack sparse matrices vertically (row wise)

**Parameters** **blocks**

sequence of sparse matrices with compatible shapes

**format** : str, optional

sparse format of the result (e.g. “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.

**dtype** : dtype, optional

The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**See also:**

**hstack** stack sparse matrices horizontally (column wise)

**Examples**

```
>>> from scipy.sparse import coo_matrix, vstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5, 6]])
>>> vstack([A, B]).toarray()
array([[1, 2],
       [3, 4],
       [5, 6]])
```

`scipy.sparse.rand` (*m, n, density=0.01, format='coo', dtype=None, random\_state=None*)

Generate a sparse matrix of the given shape and density with uniformly distributed values.

**Parameters**

- m, n** : int  
shape of the matrix
- density** : real, optional  
density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
- format** : str, optional  
sparse matrix format.
- dtype** : dtype, optional  
type of the returned matrix values.
- random\_state** : {numpy.random.RandomState, int}, optional  
Random number generator or random seed. If not given, the singleton numpy.random will be used.

**Returns**

- res** : sparse matrix

See also:

**scipy.sparse.random**

Similar function that allows a user-specified random data source.

**Notes**

Only float types are supported for now.

**Examples**

```
>>> from scipy.sparse import rand
>>> matrix = rand(3, 4, density=0.25, format="csr", random_state=42)
>>> matrix
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in Compressed Sparse Row format>
>>> matrix.todense()
matrix([[ 0.          ,  0.59685016,  0.779691   ,  0.          ],
        [ 0.          ,  0.          ,  0.          ,  0.44583275],
        [ 0.          ,  0.          ,  0.          ,  0.          ]])
```

`scipy.sparse.random(m, n, density=0.01, format='coo', dtype=None, random_state=None, data_rvs=None)`

Generate a sparse matrix of the given shape and density with randomly distributed values.

**Parameters**

- m, n** : int  
shape of the matrix
- density** : real, optional  
density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
- format** : str, optional  
sparse matrix format.
- dtype** : dtype, optional  
type of the returned matrix values.
- random\_state** : {numpy.random.RandomState, int}, optional  
Random number generator or random seed. If not given, the singleton numpy.random will be used. This random state will be used for sampling the sparsity structure, but not necessarily for sampling the values of the structurally nonzero entries of the matrix.
- data\_rvs** : callable, optional  
Samples a requested number of random values. This function should take a single argument specifying the length of the ndarray that it will return. The structurally nonzero entries of the sparse random matrix will be taken from the array sampled by this function. By default, uniform [0, 1) random

values will be sampled using the same random state as is used for sampling the sparsity structure.

**Returns** `res` : sparse matrix

**Notes**

Only float types are supported for now.

**Examples**

```
>>> from scipy.sparse import random
>>> from scipy import stats
>>> class CustomRandomState(object):
...     def randint(self, k):
...         i = np.random.randint(k)
...         return i - i % 2
>>> rs = CustomRandomState()
>>> rvs = stats.poisson(25, loc=10).rvs
>>> S = random(3, 4, density=0.25, random_state=rs, data_rvs=rvs)
>>> S.A
array([[ 36.,   0.,  33.,   0.], # random
       [  0.,   0.,   0.,   0.],
       [  0.,   0.,  36.,   0.]])
```

Save and load sparse matrices:

`save_npz(file, matrix[, compressed])`

Save a sparse matrix to a file using `.npz` format.

`load_npz(file)`

Load a sparse matrix from a file using `.npz` format.

`scipy.sparse.save_npz(file, matrix, compressed=True)`

Save a sparse matrix to a file using `.npz` format.

**Parameters** `file` : str or file-like object

Either the file name (string) or an open file (file-like object) where the data will be saved. If file is a string, the `.npz` extension will be appended to the file name if it is not already there.

**matrix**: `spmatrix` (format: `"csc"`, `"csr"`, `"bsr"`, `"dia"` or `coo`)

The sparse matrix to save.

**compressed** : bool, optional

Allow compressing the file. Default: True

See also:

`scipy.sparse.load_npz`

Load a sparse matrix from a file using `.npz` format.

`numpy.savez`

Save several arrays into a `.npz` archive.

`numpy.savez_compressed`

Save several arrays into a compressed `.npz` archive.

**Examples**

Store sparse matrix to disk, and load it again:

```
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64''>'
```

```
with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

```
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
```

```
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

`scipy.sparse.load_npz` (*file*)

Load a sparse matrix from a file using `.npz` format.

<b>Parameters</b>	<b>file</b> : str or file-like object	Either the file name (string) or an open file (file-like object) where the data will be loaded.
<b>Returns</b>	<b>result</b> : csc_matrix, csr_matrix, bsr_matrix, dia_matrix or coo_matrix	A sparse matrix containing the loaded data.
<b>Raises</b>	<b>IOError</b>	If the input file does not exist or cannot be read.

See also:

**`scipy.sparse.save_npz`**

Save a sparse matrix to a file using `.npz` format.

**`numpy.load`** Load several arrays from a `.npz` archive.

**Examples**

Store sparse matrix to disk, and load it again:

```
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

```
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
```

```
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

Sparse matrix tools:

---

<code>find(A)</code>	Return the indices and values of the nonzero elements of a matrix
----------------------	---

---

`scipy.sparse.find(A)`

Return the indices and values of the nonzero elements of a matrix

**Parameters** `A` : dense or sparse matrix

**Returns** `(I,J,V)` : tuple of arrays  
Matrix whose nonzero elements are desired.

I, J, and V contain the row indices, column indices, and values of the nonzero matrix entries.

### Examples

```
>>> from scipy.sparse import csr_matrix, find
>>> A = csr_matrix([[7.0, 8.0, 0],[0, 0, 9.0]])
>>> find(A)
(array([0, 0, 1], dtype=int32), array([0, 1, 2], dtype=int32), array([ 7.,  8.,  9.]))
```

Identifying sparse matrices:

<code>issparse(x)</code>	Is x of a sparse matrix type?
<code>isspmatrix(x)</code>	Is x of a sparse matrix type?
<code>isspmatrix_csc(x)</code>	Is x of csc_matrix type?
<code>isspmatrix_csr(x)</code>	Is x of csr_matrix type?
<code>isspmatrix_bsr(x)</code>	Is x of a bsr_matrix type?
<code>isspmatrix_lil(x)</code>	Is x of lil_matrix type?
<code>isspmatrix_dok(x)</code>	Is x of dok_matrix type?
<code>isspmatrix_coo(x)</code>	Is x of coo_matrix type?
<code>isspmatrix_dia(x)</code>	Is x of dia_matrix type?

`scipy.sparse.issparse(x)`

Is x of a sparse matrix type?

**Parameters** `x`

**Returns** `bool` object to check for being a sparse matrix

True if x is a sparse matrix, False otherwise

### Notes

`issparse` and `isspmatrix` are aliases for the same function.

### Examples

```
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

`scipy.sparse.isspmatrix(x)`

Is x of a sparse matrix type?

<b>Parameters</b>	<b>x</b>	object to check for being a sparse matrix
<b>Returns</b>	bool	True if x is a sparse matrix, False otherwise

**Notes**

issparse and isspmatrix are aliases for the same function.

**Examples**

```
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

`scipy.sparse.isspmatrix_csc(x)`

Is x of csc\_matrix type?

<b>Parameters</b>	<b>x</b>	object to check for being a csc matrix
<b>Returns</b>	bool	True if x is a csc matrix, False otherwise

**Examples**

```
>>> from scipy.sparse import csc_matrix, isspmatrix_csc
>>> isspmatrix_csc(csc_matrix([[5]]))
True
```

```
>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csc(csr_matrix([[5]]))
False
```

`scipy.sparse.isspmatrix_csr(x)`

Is x of csr\_matrix type?

<b>Parameters</b>	<b>x</b>	object to check for being a csr matrix
<b>Returns</b>	bool	True if x is a csr matrix, False otherwise

**Examples**

```
>>> from scipy.sparse import csr_matrix, isspmatrix_csr
>>> isspmatrix_csr(csr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csr(csc_matrix([[5]]))
False
```

`scipy.sparse.isspmatrix_bsr(x)`

Is x of a bsr\_matrix type?

<b>Parameters</b>	<b>x</b>	object to check for being a bsr matrix
<b>Returns</b>	bool	True if x is a bsr matrix, False otherwise

#### Examples

```
>>> from scipy.sparse import bsr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(bsr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import bsr_matrix, csr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(csr_matrix([[5]]))
False
```

`scipy.sparse.isspmatrix_lil(x)`

Is x of lil\_matrix type?

<b>Parameters</b>	<b>x</b>	object to check for being a lil matrix
<b>Returns</b>	bool	True if x is a lil matrix, False otherwise

#### Examples

```
>>> from scipy.sparse import lil_matrix, isspmatrix_lil
>>> isspmatrix_lil(lil_matrix([[5]]))
True
```

```
>>> from scipy.sparse import lil_matrix, csr_matrix, isspmatrix_lil
>>> isspmatrix_lil(csr_matrix([[5]]))
False
```

`scipy.sparse.isspmatrix_dok(x)`

Is x of dok\_matrix type?

<b>Parameters</b>	<b>x</b>	object to check for being a dok matrix
<b>Returns</b>	bool	True if x is a dok matrix, False otherwise

#### Examples

```
>>> from scipy.sparse import dok_matrix, isspmatrix_dok
>>> isspmatrix_dok(dok_matrix([[5]]))
True
```

```
>>> from scipy.sparse import dok_matrix, csr_matrix, isspmatrix_dok
>>> isspmatrix_dok(csr_matrix([[5]]))
False
```

`scipy.sparse.isspmatrix_coo(x)`

Is x of coo\_matrix type?

<b>Parameters</b>	<b>x</b>	object to check for being a coo matrix
-------------------	----------	--

**Returns** bool  
True if x is a coo matrix, False otherwise

**Examples**

```
>>> from scipy.sparse import coo_matrix, isspmatrix_coo
>>> isspmatrix_coo(coo_matrix([[5]]))
True
```

```
>>> from scipy.sparse import coo_matrix, csr_matrix, isspmatrix_coo
>>> isspmatrix_coo(csr_matrix([[5]]))
False
```

`scipy.sparse.isspmatrix_dia(x)`  
Is x of `dia_matrix` type?

**Parameters** x object to check for being a dia matrix  
**Returns** bool True if x is a dia matrix, False otherwise

**Examples**

```
>>> from scipy.sparse import dia_matrix, isspmatrix_dia
>>> isspmatrix_dia(dia_matrix([[5]]))
True
```

```
>>> from scipy.sparse import dia_matrix, csr_matrix, isspmatrix_dia
>>> isspmatrix_dia(csr_matrix([[5]]))
False
```

**Submodules**

**Compressed Sparse Graph Routines (`scipy.sparse.csgraph`)**

Fast graph algorithms based on sparse matrix representations.

**Contents**

<i>connected_components</i> (csgraph[, directed, ...])	Analyze the connected components of a sparse graph
<i>laplacian</i> (csgraph[, normed, return_diag, ...])	Return the Laplacian matrix of a directed graph.
<i>shortest_path</i> (csgraph[, method, directed, ...])	Perform a shortest-path graph search on a positive directed or undirected graph.
<i>dijkstra</i> (csgraph[, directed, indices, ...])	Dijkstra algorithm using Fibonacci Heaps
<i>floyd_warshall</i> (csgraph[, directed, ...])	Compute the shortest path lengths using the Floyd-Warshall algorithm

Continued on next page

Table 5.184 – continued from previous page

<code>bellman_ford(csgraph[, directed, indices, ...])</code>	Compute the shortest path lengths using the Bellman-Ford algorithm.
<code>johnson(csgraph[, directed, indices, ...])</code>	Compute the shortest path lengths using Johnson's algorithm.
<code>breadth_first_order(csgraph, i_start[, ...])</code>	Return a breadth-first ordering starting with specified node.
<code>depth_first_order(csgraph, i_start[, ...])</code>	Return a depth-first ordering starting with specified node.
<code>breadth_first_tree(csgraph, i_start[, directed])</code>	Return the tree generated by a breadth-first search
<code>depth_first_tree(csgraph, i_start[, directed])</code>	Return a tree generated by a depth-first search.
<code>minimum_spanning_tree(csgraph[, overwrite])</code>	Return a minimum spanning tree of an undirected graph
<code>reverse_cuthill_mckee(graph[, symmetric_mode])</code>	Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.
<code>maximum_bipartite_matching(graph[, perm_type])</code>	Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.
<code>structural_rank(graph)</code>	Compute the structural rank of a graph (matrix) with a given sparsity pattern.
<i>NegativeCycleError</i>	

`scipy.sparse.csgraph.connected_components` (*csgraph*, *directed=True*, *connection='weak'*, *return\_labels=True*)

Analyze the connected components of a sparse graph

New in version 0.11.0.

**Parameters** `csgraph` : array\_like or sparse matrix

The N x N matrix representing the compressed sparse graph. The input `csgraph` will be converted to `csr` format for the calculation.

**directed** : bool, optional

If `True` (default), then operate on a directed graph: only move from point `i` to point `j` along paths `csgraph[i, j]`. If `False`, then find the shortest path on an undirected graph: the algorithm can progress from point `i` to `j` along `csgraph[i, j]` or `csgraph[j, i]`.

**connection** : str, optional

['weak'|'strong']. For directed graphs, the type of connection to use. Nodes `i` and `j` are strongly connected if a path exists both from `i` to `j` and from `j` to `i`. Nodes `i` and `j` are weakly connected if only one of these paths exists. If `directed == False`, this keyword is not referenced.

**return\_labels** : bool, optional

If `True` (default), then return the labels for each of the connected components.

**Returns**

`n_components`: int

The number of connected components.

`labels`: ndarray

The length-N array of labels of the connected components.

### References

[R15]

`scipy.sparse.csgraph.laplacian` (*csgraph*, *normed=False*, *return\_diag=False*, *use\_out\_degree=False*)

Return the Laplacian matrix of a directed graph.

**Parameters** `csgraph` : array\_like or sparse matrix, 2 dimensions

compressed-sparse graph, with shape (N, N).

**normed** : bool, optional  
 If True, then compute normalized Laplacian.

**return\_diag** : bool, optional  
 If True, then also return an array related to vertex degrees.

**use\_out\_degree** : bool, optional  
 If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

**Returns** **lap** : ndarray or sparse matrix  
 The N x N laplacian matrix of csgraph. It will be a numpy array (dense) if the input was dense, or a sparse matrix otherwise.

**diag** : ndarray, optional  
 The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

**Notes**

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

**Examples**

```
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```

`scipy.sparse.csgraph.shortest_path`(*csgraph*, *method*='auto', *directed*=True, *return\_predecessors*=False, *unweighted*=False, *overwrite*=False, *indices*=None)

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters** **csgraph** : array, matrix, or sparse matrix, 2 dimensions  
 The N x N array of distances representing the input graph.

**method** : string ['auto'|'FW'|'D'], optional  
 Algorithm to use for shortest paths. Options are:  
*'auto'* – (default) select the best among *'FW'*, *'D'*, *'BF'*, or *'J'*  
 based on the input data.  
*'FW'* – *Floyd-Warshall algorithm*. Computational cost is approximately  $O[N^3]$ . The input csgraph will be converted to a dense representation.  
*'D'* – *Dijkstra's algorithm with Fibonacci heaps*. Computational cost is approximately  $O[N(N*k +$

$N \cdot \log(N)$ ], where  $k$  is the average number of connected edges per node. The input `csgraph` will be converted to a csr representation.

**‘BF’ – Bellman-Ford algorithm.** *This algorithm can be used when*

weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately  $O[N(N^2 k)]$ , where  $k$  is the average number of connected edges per node. The input `csgraph` will be converted to a csr representation.

**‘J’ – Johnson’s algorithm.** *Like the Bellman-Ford algorithm,*

Johnson’s algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra’s algorithm for faster computation.

**directed** : bool, optional

If True (default), then find the shortest path on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`

**return\_predecessors** : bool, optional

If True, return the size  $(N, N)$  predecessor matrix

**unweighted** : bool, optional

If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**overwrite** : bool, optional

If True, overwrite `csgraph` with the result. This applies only if `method == ‘FW’` and `csgraph` is a dense,  $c$ -ordered array with `dtype=float64`.

**indices** : array\_like or int, optional

If specified, only compute the paths for the points at the given indices. Incompatible with `method == ‘FW’`.

**Returns**

**dist\_matrix** : ndarray

The  $N \times N$  matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point  $i$  to point  $j$  along the graph.

**predecessors** : ndarray

Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`

**Raises**

**NegativeCycleError:**

if there are negative cycles in the graph

### Notes

As currently implemented, Dijkstra’s algorithm and Johnson’s algorithm do not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are non-equal edges, `method=‘D’` may yield an incorrect result.

```
scipy.sparse.csgraph.dijkstra(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False, limit=np.inf)
```

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

**Parameters**

- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of non-negative distances representing the input graph.
- directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- indices** : array\_like or int, optional  
if specified, only compute the paths for the points at the given indices.
- return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix
- unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- limit** : float, optional  
The maximum distance to calculate, must be  $\geq 0$ . Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance  $>$  limit. For such pairs, the distance will be equal to `np.inf` (i.e., not connected).

**Returns**

- dist\_matrix** : ndarray  
New in version 0.14.0.  
The matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.
- predecessors** : ndarray  
Returned only if `return_predecessors == True`. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

**Notes**

As currently implemented, Dijkstra's algorithm does not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are not equal and both are nonzero, setting `directed=False` will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford's algorithm or Johnson's algorithm.

`scipy.sparse.csgraph.floyd_warshall` (*csgraph*, *directed=True*, *return\_predecessors=False*, *unweighted=False*, *overwrite=False*)

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

**Parameters**

- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
- directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

**return\_predecessors** : bool, optional  
 If True, return the size (N, N) predecessor matrix

**unweighted** : bool, optional  
 If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**overwrite** : bool, optional  
 If True, overwrite csgraph with the result. This applies only if csgraph is a dense, c-ordered array with dtype=float64.

**Returns** **dist\_matrix** : ndarray  
 The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.

**predecessors** : ndarray  
 Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

**Raises** **NegativeCycleError**:  
 if there are negative cycles in the graph

```
scipy.sparse.csgraph.bellman_ford(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)
```

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra's algorithm may be faster.

New in version 0.11.0.

**Parameters** **csgraph** : array, matrix, or sparse matrix, 2 dimensions  
 The N x N array of distances representing the input graph.

**directed** : bool, optional  
 If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`

**indices** : array\_like or int, optional  
 if specified, only compute the paths for the points at the given indices.

**return\_predecessors** : bool, optional  
 If True, return the size (N, N) predecessor matrix

**unweighted** : bool, optional  
 If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns** **dist\_matrix** : ndarray  
 The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.

**predecessors** : ndarray  
 Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

**Raises** **NegativeCycleError**:  
 if there are negative cycles in the graph

*Notes*

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

`scipy.sparse.csgraph.johnson` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using Johnson's algorithm.

Johnson's algorithm combines the Bellman-Ford algorithm and Dijkstra's algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, `dijkstra()` may be faster.

New in version 0.11.0.

**Parameters**

- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
- directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`
- indices** : array\_like or int, optional  
if specified, only compute the paths for the points at the given indices.
- return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix
- unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns**

- dist\_matrix** : ndarray  
The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.
- predecessors** : ndarray  
Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

**Raises**

- NegativeCycleError**:  
if there are negative cycles in the graph

*Notes*

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

`scipy.sparse.csgraph.breadth_first_order` (*csgraph*, *i\_start*, *directed=True*, *return\_predecessors=True*)

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

**Parameters**

- csgraph** : array\_like or sparse matrix  
The N x N compressed sparse graph. The input `csgraph` will be converted to csr format for the calculation.
- i\_start** : int

The index of starting node.

**directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.

**return\_predecessors** : bool, optional  
If True (default), then return the predecessor array (see below).

**Returns** **node\_array** : ndarray, one dimension  
The breadth-first list of nodes, starting with specified node. The length of `node_array` is the number of nodes reachable from the specified node.

**predecessors** : ndarray, one dimension  
Returned only if `return_predecessors` is True. The length-*N* list of predecessors of each node in a breadth-first tree. If node *i* is in the tree, then its parent is given by `predecessors[i]`. If node *i* is not in the tree (and for the parent node) then `predecessors[i] = -9999`.

```
scipy.sparse.csgraph.depth_first_order(csgraph, i_start, directed=True,
                                     return_predecessors=True)
```

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix  
The *N* x *N* compressed sparse graph. The input `csgraph` will be converted to csr format for the calculation.

**i\_start** : int  
The index of starting node.

**directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.

**return\_predecessors** : bool, optional  
If True (default), then return the predecessor array (see below).

**Returns** **node\_array** : ndarray, one dimension  
The depth-first list of nodes, starting with specified node. The length of `node_array` is the number of nodes reachable from the specified node.

**predecessors** : ndarray, one dimension  
Returned only if `return_predecessors` is True. The length-*N* list of predecessors of each node in a depth-first tree. If node *i* is in the tree, then its parent is given by `predecessors[i]`. If node *i* is not in the tree (and for the parent node) then `predecessors[i] = -9999`.

```
scipy.sparse.csgraph.breadth_first_tree(csgraph, i_start, directed=True)
```

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix  
The *N* x *N* matrix representing the compressed sparse graph. The input `csgraph` will be converted to csr format for the calculation.

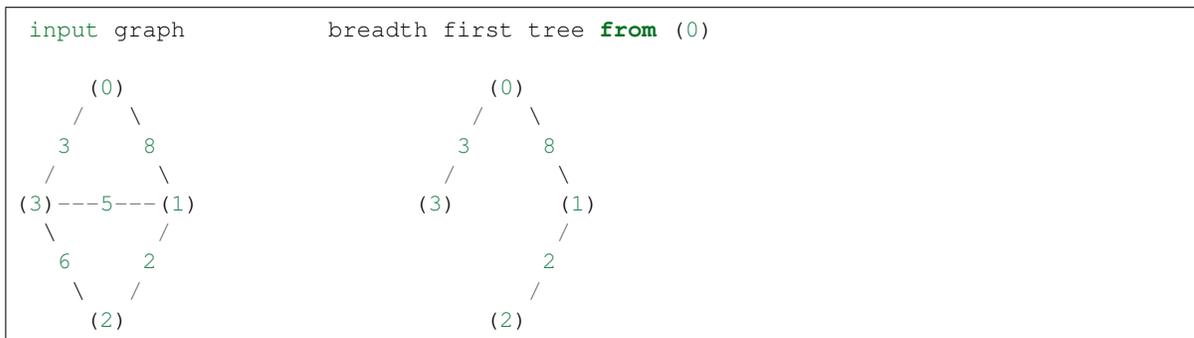

**i\_start** : int  
The index of starting node.

**directed** : bool, optional  
 If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.

**Returns** **cstree** : csr matrix  
 The *N* x *N* directed compressed-sparse representation of the breadth-first tree drawn from `csgraph`, starting at the specified node.

### Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.

`scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)`

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix  
 The *N* x *N* matrix representing the compressed sparse graph. The input `csgraph` will be converted to csr format for the calculation.

**i\_start** : int  
 The index of starting node.

**directed** : bool, optional

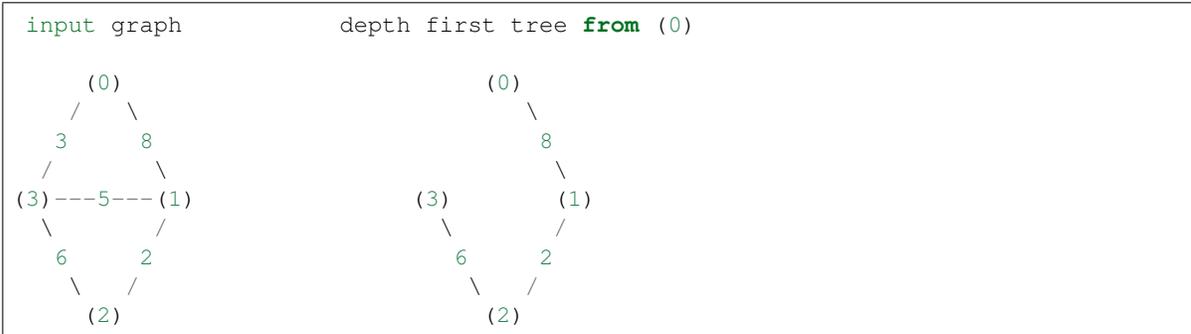

**Returns** **cstree** : csr matrix

If True (default), then operate on a directed graph: only move from point  $i$  to point  $j$  along paths  $\text{csgraph}[i, j]$ . If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along  $\text{csgraph}[i, j]$  or  $\text{csgraph}[j, i]$ .

The  $N \times N$  directed compressed-sparse representation of the depth- first tree drawn from  $\text{csgraph}$ , starting at the specified node.

### Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
       [0, 0, 0, 6],
       [0, 0, 0, 0]])
    
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

`scipy.sparse.csgraph.minimum_spanning_tree` (*csgraph*, *overwrite=False*)

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix, 2 dimensions  
 The  $N \times N$  matrix representing an undirected graph over  $N$  nodes (see notes below).

**overwrite** : bool, optional  
 if true, then parts of the input graph will be overwritten for efficiency.

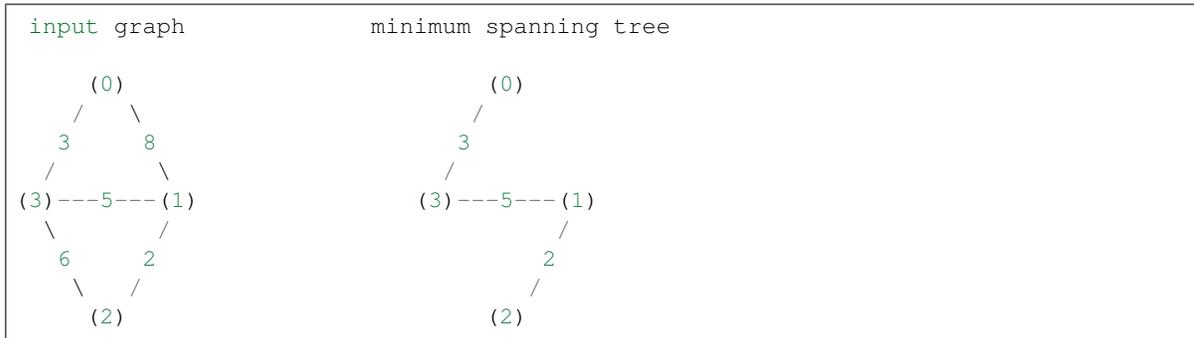

**Returns** **span\_tree** : csr matrix  
 The  $N \times N$  compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

**Notes**

This routine uses undirected graphs as input and output. That is, if `graph[i, j]` and `graph[j, i]` are both zero, then nodes `i` and `j` do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

**Examples**

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

`scipy.sparse.csgraph.reverse_cuthill_mckee` (*graph*, *symmetric\_mode=False*)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, `symmetric_mode=False`, that the input matrix is not symmetric and works on the matrix `A+A.T`. If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set `symmetric_mode=True`.

- Parameters**

  - graph** : sparse matrix  
Input sparse in CSC or CSR sparse matrix format.
  - symmetric\_mode** : bool, optional  
Is input matrix guaranteed to be symmetric.

- Returns**

  - perm** : ndarray  
Array of permuted row and column indices.

**Notes**

New in version 0.15.0.

Table 5.185 – continued from previous page

---

<code>reconstruct_path(csgraph, predecessors[, ...])</code>	Construct a tree from a graph and a predecessor list.
---	---

---

`scipy.sparse.csgraph.construct_dist_matrix` (*graph*, *predecessors*, *directed=True*, *null\_value=np.inf*)

Construct distance matrix from a predecessor matrix

New in version 0.11.0.

**Parameters**

- graph** : array\_like or sparse  
The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.
- predecessors** : array\_like  
The N x N matrix of predecessors of each node (see Notes below).
- directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then operate on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- null\_value** : bool, optional  
value to use for distances between unconnected nodes. Default is `np.inf`

**Returns**

- dist\_matrix** : ndarray  
The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

**Notes**

The predecessor matrix is of the form returned by `graph_shortest_path`. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

`scipy.sparse.csgraph.csgraph_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*, *infinity\_null=True*)

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

**Parameters**

- graph** : array\_like  
Input graph. Shape should be (n\_nodes, n\_nodes).
- null\_value** : float or None (optional)  
Value that denotes non-edges in the graph. Default is zero.
- infinity\_null** : bool  
If True (default), then infinite entries (both positive and negative) are treated as null edges.
- nan\_null** : bool  
If True (default), then NaN entries are treated as non-edges

**Returns**

- csgraph** : csr\_matrix  
Compressed sparse representation of graph,

`scipy.sparse.csgraph.csgraph_from_masked` (*graph*)

Construct a CSR-format graph from a masked array.

New in version 0.11.0.

**Parameters**

- graph** : MaskedArray  
Input graph. Shape should be (n\_nodes, n\_nodes).

**Returns**

- csgraph** : csr\_matrix  
Compressed sparse representation of graph,

`scipy.sparse.csgraph.csgraph_masked_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*,  
*infinity\_null=True*, *copy=True*)

Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

**Parameters**

- graph** : array\_like  
Input graph. Shape should be (n\_nodes, n\_nodes).
- null\_value** : float or None (optional)  
Value that denotes non-edges in the graph. Default is zero.
- infinity\_null** : bool  
If True (default), then infinite entries (both positive and negative) are treated as null edges.
- nan\_null** : bool  
If True (default), then NaN entries are treated as non-edges

**Returns**

- csgraph** : MaskedArray  
masked array representation of graph

`scipy.sparse.csgraph.csgraph_to_dense` (*csgraph*, *null\_value=0*)

Convert a sparse graph representation to a dense representation

New in version 0.11.0.

**Parameters**

- csgraph** : csr\_matrix, csc\_matrix, or lil\_matrix  
Sparse representation of a graph.
- null\_value** : float, optional  
The value used to indicate null edges in the dense representation. Default is 0.

**Returns**

- graph** : ndarray  
The dense representation of the sparse graph.

### Notes

For normal sparse graph representations, calling `csgraph_to_dense` with `null_value=0` produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in `scipy.sparse` will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we'll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 5],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
       [0., 0.]])
```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default `scipy.sparse` behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let's look at the example of a two-node directed graph, connected by an edge of weight zero:

```

>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[ inf,  0.],
       [ inf,  inf]])
    
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

`scipy.sparse.csgraph.csgraph_to_masked(csgraph)`

Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

**Parameters** **csgraph** : `csr_matrix`, `csc_matrix`, or `lil_matrix`

**Returns** **graph** : `MaskedArray` Sparse representation of a graph.

The masked dense representation of the sparse graph.

`scipy.sparse.csgraph.reconstruct_path(csgraph, predecessors, directed=True)`

Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

**Parameters** **csgraph** : `array_like` or sparse matrix

The  $N \times N$  matrix representing the directed or undirected graph from which the predecessors are drawn.

**predecessors** : `array_like`, one dimension

The length- $N$  array of indices of predecessors for the tree. The index of the parent of node  $i$  is given by `predecessors[i]`.

**directed** : `bool`, optional

If `True` (default), then operate on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If `False`, then operate on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`.

**Returns** **cstree** : `csr matrix`

The  $N \times N$  directed compressed-sparse representation of the tree drawn from `csgraph` which is encoded by the predecessor list.

## Graph Representations

This module uses graphs which are stored in a matrix format. A graph with  $N$  nodes can be represented by an  $(N \times N)$  adjacency matrix  $G$ . If there is a connection from node  $i$  to node  $j$ , then  $G[i, j] = w$ , where  $w$  is the weight of the connection. For nodes  $i$  and  $j$  which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by  $G[i, j] = 0$ , infinity, or `NaN`.
- for dense masked representations (of type `np.ma.MaskedArray`), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```

>>> G_dense = np.array([[0, 2, 1],
...                    [2, 0, 0],
...                    [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)
  
```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```

>>> G2_data = np.array([[np.inf, 2, 0 ],
...                    [2, np.inf, np.inf],
...                    [0, np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([ 2.,  0.,  2.,  0.])
  
```

Here we have used a utility routine from the `csgraph` submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

## Directed vs. Undirected

Matrices may represent either directed or undirected graphs. This is specified throughout the `csgraph` module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node  $i$  to node  $j$  can be accomplished over the edge  $G[i, j]$ , but not the edge  $G[j, i]$ . In a non-directed graph, traversal from node  $i$  to node  $j$  can be accomplished over either  $G[i, j]$  or  $G[j, i]$ . If both edges are not null, and the two have unequal weights,

then the smaller of the two is used. Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘directed’ keyword is set to True or False. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either `scipy.sparse` representations (`csr`, `csc`, or `lil` format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.

### Functions

<code>bellman_ford(csgraph[, directed, indices, ...])</code>	Compute the shortest path lengths using the Bellman-Ford algorithm.
<code>breadth_first_order(csgraph, i_start[, ...])</code>	Return a breadth-first ordering starting with specified node.
<code>breadth_first_tree(csgraph, i_start[, directed])</code>	Return the tree generated by a breadth-first search
<code>connected_components(csgraph[, directed, ...])</code>	Analyze the connected components of a sparse graph
<code>construct_dist_matrix(graph, predecessors[, ...])</code>	Construct distance matrix from a predecessor matrix
<code>csgraph_from_dense(graph[, null_value, ...])</code>	Construct a CSR-format sparse graph from a dense matrix.
<code>csgraph_from_masked(graph)</code>	Construct a CSR-format graph from a masked array.
<code>csgraph_masked_from_dense(graph[, ...])</code>	Construct a masked array graph representation from a dense matrix.
<code>csgraph_to_dense(csgraph[, null_value])</code>	Convert a sparse graph representation to a dense representation
<code>csgraph_to_masked(csgraph)</code>	Convert a sparse graph representation to a masked array representation
<code>depth_first_order(csgraph, i_start[, ...])</code>	Return a depth-first ordering starting with specified node.
<code>depth_first_tree(csgraph, i_start[, directed])</code>	Return a tree generated by a depth-first search.
<code>dijkstra(csgraph[, directed, indices, ...])</code>	Dijkstra algorithm using Fibonacci Heaps
<code>floyd_warshall(csgraph[, directed, ...])</code>	Compute the shortest path lengths using the Floyd-Warshall algorithm
<code>johnson(csgraph[, directed, indices, ...])</code>	Compute the shortest path lengths using Johnson’s algorithm.
<code>laplacian(csgraph[, normed, return_diag, ...])</code>	Return the Laplacian matrix of a directed graph.
<code>maximum_bipartite_matching(graph[, perm_type])</code>	Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.
<code>minimum_spanning_tree(csgraph[, overwrite])</code>	Return a minimum spanning tree of an undirected graph
<code>reconstruct_path(csgraph, predecessors[, ...])</code>	Construct a tree from a graph and a predecessor list.
<code>reverse_cuthill_mckee(graph[, symmetric_mode])</code>	Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.
<code>shortest_path(csgraph[, method, directed, ...])</code>	Perform a shortest-path graph search on a positive directed or undirected graph.
<code>structural_rank(graph)</code>	Compute the structural rank of a graph (matrix) with a given sparsity pattern.

### Exceptions

`NegativeCycleError`

## Sparse linear algebra (`scipy.sparse.linalg`)

### Abstract linear operators

---

<code>LinearOperator(dtype, shape)</code>	Common interface for performing matrix vector products
<code>aslinearoperator(A)</code>	Return A as a LinearOperator.

---

**class** `scipy.sparse.linalg.LinearOperator` (*dtype, shape*)

Common interface for performing matrix vector products

Many iterative methods (e.g. `cg`, `gmres`) do not need to know the individual entries of a matrix to solve a linear system  $A*x=b$ . Such solvers only require the computation of matrix vector products,  $A*v$  where  $v$  is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete `LinearOperator`, either pass appropriate callables to the constructor of this class, or subclass it.

A subclass must implement either one of the methods `_matvec` and `_matmat`, and the attributes/properties `shape` (pair of integers) and `dtype` (may be `None`). It may call the `__init__` on this class to have these attributes validated. Implementing `_matvec` automatically implements `_matmat` (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement `_rmatvec` or `_adjoint` to implement the Hermitian adjoint (conjugate transpose). As with `_matvec` and `_matmat`, implementing either `_rmatvec` or `_adjoint` implements the other automatically. Implementing `_adjoint` is preferable; `_rmatvec` is mostly there for backwards compatibility.

**Parameters**

- shape** : tuple  
Matrix dimensions (M,N).
- matvec** : callable `f(v)`  
Returns returns  $A * v$ .
- rmatvec** : callable `f(v)`  
Returns  $A^H * v$ , where  $A^H$  is the conjugate transpose of  $A$ .
- matmat** : callable `f(V)`  
Returns  $A * V$ , where  $V$  is a dense matrix with dimensions (N,K).
- dtype** : dtype  
Data type of the matrix.

See also:

**aslinearoperator**

Construct `LinearOperator`s

**Notes**

The user-defined `matvec()` function must properly handle the case where  $v$  has shape  $(N,)$  as well as the  $(N,1)$  case. The shape of the return type is handled internally by `LinearOperator`.

`LinearOperator` instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite `LinearOperator`, that defers linear operations to the original operators and combines the results.

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...     return np.array([2*v[0], 3*v[1]])
...
>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
```

```
>>> A.matvec(np.ones(2))
array([ 2.,  3.])
>>> A * np.ones(2)
array([ 2.,  3.])
```

**Attributes**

args	(tuple) For linear operators describing products etc. of other linear operators, the operands of the binary operation.
------	--

**Methods**

<code>__call__(x)</code>	
<code>adjoint()</code>	Hermitian adjoint.
<code>dot(x)</code>	Matrix-matrix or matrix-vector multiplication.
<code>matmat(X)</code>	Matrix-matrix multiplication.
<code>matvec(x)</code>	Matrix-vector multiplication.
<code>rmatvec(x)</code>	Adjoint matrix-vector multiplication.
<code>transpose()</code>	Transpose this linear operator.

`LinearOperator.__call__(x)`

`LinearOperator.adjoint()`

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

**Returns** **A\_H** : LinearOperator  
Hermitian adjoint of self.

`LinearOperator.dot(x)`

Matrix-matrix or matrix-vector multiplication.

**Parameters** **x** : array\_like

**Returns** **Ax** : array 1-d or 2-d array, representing a vector or matrix.

1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

`LinearOperator.matmat(X)`

Matrix-matrix multiplication.

Performs the operation  $y=A*X$  where A is an MxN linear operator and X dense N\*K matrix or ndarray.

**Parameters** **X** : {matrix, ndarray}

**Returns** **Y** : {matrix, ndarray} An array with shape (N,K).

A matrix or ndarray with shape (M,K) depending on the type of the X argument.

**Notes**

This matmat wraps any user-specified matmat routine or overridden `_matmat` method to ensure that y has the correct type.

`LinearOperator.matvec(x)`

Matrix-vector multiplication.

Performs the operation  $y=A*x$  where  $A$  is an  $M \times N$  linear operator and  $x$  is a column vector or 1-d array.

**Parameters**  $x$  : {matrix, ndarray}

**Returns**  $y$  : {matrix, ndarray} An array with shape (N,) or (N,1).

A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the  $x$  argument.

#### Notes

This `matvec` wraps the user-specified `matvec` routine or overridden `_matvec` method to ensure that  $y$  has the correct shape and type.

`LinearOperator.rmatvec(x)`

Adjoint matrix-vector multiplication.

Performs the operation  $y = A^H * x$  where  $A$  is an  $M \times N$  linear operator and  $x$  is a column vector or 1-d array.

**Parameters**  $x$  : {matrix, ndarray}

**Returns**  $y$  : {matrix, ndarray} An array with shape (M,) or (M,1).

A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the  $x$  argument.

#### Notes

This `rmatvec` wraps the user-specified `rmatvec` routine or overridden `_rmatvec` method to ensure that  $y$  has the correct shape and type.

`LinearOperator.transpose()`

Transpose this linear operator.

Returns a `LinearOperator` that represents the transpose of this one. Can be abbreviated `self.T` instead of `self.transpose()`.

`scipy.sparse.linalg.aslinearoperator(A)`

Return  $A$  as a `LinearOperator`.

*'A' may be any of the following types:*

- ndarray
- matrix
- sparse matrix (e.g. `csr_matrix`, `lil_matrix`, etc.)
- `LinearOperator`
- An object with `.shape` and `.matvec` attributes

See the `LinearOperator` documentation for additional information.

#### Examples

```
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1, 2, 3], [4, 5, 6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

## Matrix Operations

<code>inv(A)</code>	Compute the inverse of a sparse matrix
<code>expm(A)</code>	Compute the matrix exponential using Pade approximation.
<code>expm_multiply(A, B[, start, stop, num, endpoint])</code>	Compute the action of the matrix exponential of A on B.

`scipy.sparse.linalg.inv(A)`

Compute the inverse of a sparse matrix

**Parameters** **A** : (M,M) ndarray or sparse matrix  
**Returns** **Ainv** : (M,M) ndarray or sparse matrix  
 square matrix to be inverted  
 inverse of A

**Notes**

This computes the sparse inverse of A. If the inverse of A is expected to be non-sparse, it will likely be faster to convert A to dense and use `scipy.linalg.inv`.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import inv
>>> A = csc_matrix([[1., 0.], [1., 2.]])
>>> Ainv = inv(A)
>>> Ainv
<2x2 sparse matrix of type '<class 'numpy.float64''>'
  with 3 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv)
<2x2 sparse matrix of type '<class 'numpy.float64''>'
  with 2 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv).todense()
matrix([[ 1.,  0.],
        [ 0.,  1.]])
```

New in version 0.12.0.

`scipy.sparse.linalg.expm(A)`

Compute the matrix exponential using Pade approximation.

**Parameters** **A** : (M,M) array\_like or sparse matrix  
**Returns** **expA** : (M,M) ndarray  
 2D Array or Matrix (sparse or dense) to be exponentiated  
 Matrix exponential of A

**Notes**

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

**References**

[R22]

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm
>>> A = csc_matrix([[1, 0, 0], [0, 2, 0], [0, 0, 3]])
>>> A.todense()
```

```

matrix([[1, 0, 0],
        [0, 2, 0],
        [0, 0, 3]], dtype=int64)
>>> Aexp = expm(A)
>>> Aexp
<3x3 sparse matrix of type '<class 'numpy.float64''>'
  with 3 stored elements in Compressed Sparse Column format>
>>> Aexp.todense()
matrix([[ 2.71828183,  0.          ,  0.          ],
        [ 0.          ,  7.3890561 ,  0.          ],
        [ 0.          ,  0.          , 20.08553692]])

```

`scipy.sparse.linalg.expm_multiply` (*A*, *B*, *start=None*, *stop=None*, *num=None*, *endpoint=None*)

Compute the action of the matrix exponential of *A* on *B*.

**Parameters**

- A** : transposable linear operator  
The operator whose exponential is of interest.
- B** : ndarray  
The matrix or vector to be multiplied by the matrix exponential of *A*.
- start** : scalar, optional  
The starting time point of the sequence.
- stop** : scalar, optional  
The end time point of the sequence, unless *endpoint* is set to False. In that case, the sequence consists of all but the last of *num* + 1 evenly spaced time points, so that *stop* is excluded. Note that the step size changes when *endpoint* is False.
- num** : int, optional  
Number of time points to use.
- endpoint** : bool, optional  
If True, *stop* is the last time point. Otherwise, it is not included.

**Returns**

- expm\_A\_B** : ndarray  
The result of the action  $e^{t_k A} B$ .

### Notes

The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of `numpy.linspace`.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, `expm_A_B[0]` will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

### References

[R23], [R24]

### Examples

```

>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm, expm_multiply
>>> A = csc_matrix([[1, 0], [0, 1]])
>>> A.todense()
matrix([[1, 0],
        [0, 1]], dtype=int64)
>>> B = np.array([np.exp(-1.), np.exp(-2.)])

```

```

>>> B
array([ 0.36787944,  0.13533528])
>>> expm_multiply(A, B, start=1, stop=2, num=3, endpoint=True)
array([[ 1.          ,  0.36787944],
       [ 1.64872127,  0.60653066],
       [ 2.71828183,  1.          ]])
>>> expm(A).dot(B) # Verify 1st timestep
array([ 1.          ,  0.36787944])
>>> expm(1.5*A).dot(B) # Verify 2nd timestep
array([ 1.64872127,  0.60653066])
>>> expm(2*A).dot(B) # Verify 3rd timestep
array([ 2.71828183,  1.          ])

```

## Matrix norms

<code>norm(x[, ord, axis])</code>	Norm of a sparse matrix
<code>onenormest(A[, t, itmax, compute_v, compute_w])</code>	Compute a lower bound of the 1-norm of a sparse matrix.

`scipy.sparse.linalg.norm(x, ord=None, axis=None)`

Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the `ord` parameter.

**Parameters**

- x** : a sparse matrix  
Input sparse matrix.
- ord** : {non-zero int, inf, -inf, 'fro'}, optional  
Order of the norm (see table under `Notes`). `inf` means numpy's `inf` object.
- axis** : {int, 2-tuple of ints, None}, optional  
If `axis` is an integer, it specifies the axis of `x` along which to compute the vector norms. If `axis` is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If `axis` is `None` then either a vector norm (when `x` is 1-D) or a matrix norm (when `x` is 2-D) is returned.

**Returns**

- n** : float or ndarray

### Notes

Some of the `ord` are not implemented because some associated functions like, `_multi_svd_norm`, are not yet available for sparse matrix.

This docstring is modified based on `numpy.linalg.norm`. <https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py>

The following norms can be calculated:

ord	norm for sparse matrices
None	Frobenius norm
'fro'	Frobenius norm
inf	max(sum(abs(x), axis=1))
-inf	min(sum(abs(x), axis=1))
0	abs(x).sum(axis=axis)
1	max(sum(abs(x), axis=0))
-1	min(sum(abs(x), axis=0))
2	Not implemented
-2	Not implemented
other	Not implemented

The Frobenius norm is given by [R38]:

$$\|A\|_F = [\sum_{i,j} \text{abs}(a_{i,j})^2]^{1/2}$$

### References

[R38]

### Examples

```
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1, 0, 1, 2, 3, 4])
>>> b = a.reshape((3, 3))
>>> b
array([[ -4,  -3,  -2],
       [ -1,  0,  1],
       [  2,  3,  4]])
```

```
>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
>>> norm(b, -1)
6
```

`scipy.sparse.linalg.onenormest` ( $A$ ,  $t=2$ ,  $itmax=5$ ,  $compute_v=False$ ,  $compute_w=False$ )

Compute a lower bound of the 1-norm of a sparse matrix.

**Parameters**  $A$  : ndarray or other linear operator

A linear operator that can be transposed and that can produce matrix products.

$t$  : int, optional

A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.

**itmax** : int, optional  
 Use at most this many iterations.

**compute\_v** : bool, optional  
 Request a norm-maximizing linear operator input vector if True.

**compute\_w** : bool, optional  
 Request a norm-maximizing linear operator output vector if True.

**Returns** **est** : float  
 An underestimate of the 1-norm of the sparse matrix.

**v** : ndarray, optional  
 The vector such that  $\|Av\|_1 == est * \|v\|_1$ . It can be thought of as an input to the linear operator that gives an output with particularly large norm.

**w** : ndarray, optional  
 The vector  $Av$  which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

**Notes**

This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about  $4t$  matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import onenormest
>>> A = csc_matrix([[1., 0., 0.], [5., 8., 2.], [0., -1., 0.]], dtype=float)
>>> A.todense()
matrix([[ 1.,  0.,  0.],
        [ 5.,  8.,  2.],
        [ 0., -1.,  0.]])
>>> onenormest(A)
9.0
>>> np.linalg.norm(A.todense(), ord=1)
9.0
```

**Solving linear problems**

Direct methods for linear equation systems:

<code>spsolve(A, b[, permc_spec, use_umfpack])</code>	Solve the sparse linear system $Ax=b$ , where $b$ may be a vector or a matrix.
<code>spsolve_triangular(A, b[, lower, ...])</code>	Solve the equation $Ax = b$ for $x$ , assuming $A$ is a triangular matrix.
<code>factorized(A)</code>	Return a function for solving a sparse linear system, with $A$ pre-factorized.
<code>MatrixRankWarning</code>	

Continued on next page

Table 5.192 – continued from previous page

<code>use_solver(**kwargs)</code>	Select default sparse direct solver to be used.
-----------------------------------	---

`scipy.sparse.linalg.spsolve` (*A*, *b*, *perm\_spec=None*, *use\_umfpack=True*)

Solve the sparse linear system  $Ax=b$ , where *b* may be a vector or a matrix.

**Parameters**

- A** : ndarray or sparse matrix  
The square matrix *A* will be converted into CSC or CSR form
- b** : ndarray or sparse matrix  
The matrix or vector representing the right hand side of the equation. If a vector, *b.shape* must be (n,) or (n, 1).
- perm\_spec** : str, optional  
How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')
  - NATURAL: natural ordering.
  - MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
  - MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T+A$ .
  - COLAMD: approximate minimum degree column ordering
- use\_umfpack** : bool, optional  
if True (default) then use umfpack for the solution. This is only referenced if *b* is a vector and `scikit-umfpack` is installed.

**Returns**

- x** : ndarray or sparse matrix  
the solution of the sparse linear equation. If *b* is a vector, then *x* is a vector of size *A.shape*[1] If *b* is a matrix, then *x* is a matrix of size (*A.shape*[1], *b.shape*[1])

### Notes

For solving the matrix expression  $AX = B$ , this solver assumes the resulting matrix *X* is sparse, as is often the case for very sparse inputs. If the resulting *X* is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting *A* to a dense matrix and using `scipy.linalg.solve` or its variants.

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spsolve
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> B = csc_matrix([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve(A, B)
>>> np.allclose(A.dot(x).todense(), B.todense())
True
```

`scipy.sparse.linalg.spsolve_triangular` (*A*, *b*, *lower=True*, *overwrite\_A=False*, *overwrite\_b=False*)

Solve the equation  $Ax = b$  for *x*, assuming *A* is a triangular matrix.

**Parameters**

- A** : (M, M) sparse matrix  
A sparse square triangular matrix. Should be in CSR format.
- b** : (M,) or (M, N) array\_like  
Right-hand side matrix in  $Ax = b$
- lower** : bool, optional  
Whether *A* is a lower or upper triangular matrix. Default is lower triangular matrix.
- overwrite\_A** : bool, optional

Allow changing  $A$ . The indices of  $A$  are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.

**overwrite\_b** : bool, optional

Allow overwriting data in  $b$ . Enabling gives a performance gain. Default is False. If *overwrite\_b* is True, it should be ensured that  $b$  has an appropriate dtype to be able to store the result.

**Returns**

**x** : (M,) or (M, N) ndarray

**Raises**

**LinAlgError**

Solution to the system  $Ax = b$ . Shape of return matches shape of  $b$ .

If  $A$  is singular or not triangular.

**ValueError**

If shape of  $A$  or shape of  $b$  do not match the requirements.

**Notes**

New in version 0.19.0.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.linalg import spsolve_triangular
>>> A = csr_matrix([[3, 0, 0], [1, -1, 0], [2, 0, 1]], dtype=float)
>>> B = np.array([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve_triangular(A, B)
>>> np.allclose(A.dot(x), B)
True
```

`scipy.sparse.linalg.factorized(A)`

Return a function for solving a sparse linear system, with  $A$  pre-factorized.

**Parameters** **A** : (N, N) array\_like

Input.

**Returns** **solve** : callable

To solve the linear system of equations given in  $A$ , the *solve* callable should be passed an ndarray of shape (N,).

**Examples**

```
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[ 3. ,  2. , -1. ],
...             [ 2. , -2. ,  4. ],
...             [-1. ,  0.5, -1. ]])
>>> solve = factorized(A) # Makes LU decomposition.
>>> rhs1 = np.array([1, -2, 0])
>>> solve(rhs1) # Uses the LU factors.
array([ 1., -2., -2.])
```

**exception** `scipy.sparse.linalg.MatrixRankWarning`

`scipy.sparse.linalg.use_solver(**kwargs)`

Select default sparse direct solver to be used.

**Parameters** **useUmfpack** : bool, optional

Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True

**assumeSortedIndices** : bool, optional

Allow UMFPACK to skip the step of sorting indices for a CSR/CSC matrix. Has effect only if useUmfpack is True and scikits.umfpack is installed. Default: False

**Notes**

The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing useUmfpack = False, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass assumeSortedIndices=True to gain some speed.

Iterative methods for linear equation systems:

<code>bicg(A, b[, x0, tol, maxiter, M, callback])</code>	Use BIConjugate Gradient iteration to solve $Ax = b$ .
<code>bicgstab(A, b[, x0, tol, maxiter, M, callback])</code>	Use BIConjugate Gradient STABILized iteration to solve $Ax = b$ .
<code>cg(A, b[, x0, tol, maxiter, M, callback])</code>	Use Conjugate Gradient iteration to solve $Ax = b$ .
<code>cgs(A, b[, x0, tol, maxiter, M, callback])</code>	Use Conjugate Gradient Squared iteration to solve $Ax = b$ .
<code>gmres(A, b[, x0, tol, restart, maxiter, M, ...])</code>	Use Generalized Minimal RESidual iteration to solve $Ax = b$ .
<code>lgmres(A, b[, x0, tol, maxiter, M, ...])</code>	Solve a matrix equation using the LGMRES algorithm.
<code>minres(A, b[, x0, shift, tol, maxiter, M, ...])</code>	Use MINimum RESidual iteration to solve $Ax=b$
<code>qmr(A, b[, x0, tol, maxiter, M1, M2, callback])</code>	Use Quasi-Minimal Residual iteration to solve $Ax = b$ .
<code>gcrotmk(A, b[, x0, tol, maxiter, M, ...])</code>	Solve a matrix equation using flexible GCROT(m,k) algorithm.

`scipy.sparse.linalg.bicg(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)`  
 Use BIConjugate Gradient iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}  
 The real or complex N-by-N matrix of the linear system. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

**b** : {array, matrix}  
 Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns** **x** : {array, matrix}  
 The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}  
 Starting guess for the solution.

**tol** : float  
 Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer  
 Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}  
 Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of conver-

gence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

`scipy.sparse.linalg.bicgstab` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*)

Use BIConjugate Gradient STABILized iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real or complex N-by-N matrix of the linear system.

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}

Starting guess for the solution.

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for *A*. The preconditioner should approximate the inverse of *A*. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

`scipy.sparse.linalg.cg` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*)

Use Conjugate Gradient iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real or complex N-by-N matrix of the linear system. *A* must represent a hermitian, positive definite matrix.

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}

Starting guess for the solution.

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

`scipy.sparse.linalg.cg`s (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*)

Use Conjugate Gradient Squared iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real-valued N-by-N matrix of the linear system.

**b** : {array, matrix}

Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns** **x** : {array, matrix}

The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}

Starting guess for the solution.

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

`scipy.sparse.linalg.gmres` (*A*, *b*, *x0=None*, *tol=1e-05*, *restart=None*, *maxiter=None*, *M=None*, *callback=None*, *restrt=None*)

Use Generalized Minimal RESidual iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real or complex N-by-N matrix of the linear system.

**b** : {array, matrix}

Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns** **x** : {array, matrix}

The converged solution.

**info** : int

*Provides convergence information:*

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

*Other Parameters*

- x0** : {array, matrix}  
Starting guess for the solution (a vector of zeros by default).
- tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- restart** : int, optional  
Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.
- maxiter** : int, optional  
Maximum number of iterations (restart cycles). Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}  
Inverse of the preconditioner of A. M should approximate the inverse of A and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.
- callback** : function  
User-supplied function to call after each iteration. It is called as callback(rk), where rk is the current residual vector.
- restrt** : int, optional  
DEPRECATED - use *restart* instead.

**See also:***LinearOperator**Notes*

A preconditioner, P, is chosen such that P is close to A but easy to solve for. The preconditioner parameter required by this routine is  $M = P^{-1}$ . The inverse should preferably not be calculated explicitly. Rather, use the following template to produce M:

```
# Construct a linear operator that computes P^-1 * x.
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

*Examples*

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import gmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = gmres(A, b)
>>> print(exitCode)           # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

```
scipy.sparse.linalg.lgmres(A, b, x0=None, tol=1e-05, maxiter=1000, M=None, callback=None,
                           inner_m=30, outer_k=3, outer_v=None, store_outer_Av=True,
                           prepend_outer_v=False)
```

Solve a matrix equation using the LGMRES algorithm.

The LGMRES algorithm [R28] [R29] is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

**Parameters**

**A** : {sparse matrix, dense matrix, LinearOperator}  
The real or complex N-by-N matrix of the linear system.

**b** : {array, matrix}  
Right hand side of the linear system. Has shape (N,) or (N,1).

**x0** : {array, matrix}  
Starting guess for the solution.

**tol** : float, optional  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : int, optional  
Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}, optional  
Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function, optional  
User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**inner\_m** : int, optional  
Number of inner GMRES iterations per each outer iteration.

**outer\_k** : int, optional  
Number of vectors to carry between inner GMRES iterations. According to [R28], good values are in the range of 1...3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.

**outer\_v** : list of tuples, optional  
List containing tuples  $(v, Av)$  of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element `Av` can be *None* if the matrix-vector product should be re-evaluated. This parameter is modified in-place by *lgmres*, and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems.

**store\_outer\_Av** : bool, optional  
Whether LGMRES should store also  $A*v$  in addition to vectors  $v$  in the *outer\_v* list. Default is True.

**prepend\_outer\_v** : bool, optional  
Whether to put *outer\_v* augmentation vectors before Krylov iterates. In standard LGMRES, `prepend_outer_v=False`.

**Returns**

**x** : array or matrix  
The converged solution.

**info** : int  
Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

**Notes**

The LGMRES algorithm [R28] [R29] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the *outer\_v* argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

**References**

[R28], [R29]

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lgmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = lgmres(A, b)
>>> print(exitCode)           # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

`scipy.sparse.linalg.minres(A, b, x0=None, shift=0.0, tol=1e-05, maxiter=None, M=None, callback=None, show=False, check=False)`

Use MINimum RESidual iteration to solve  $Ax=b$

MINRES minimizes  $\text{norm}(A*x - b)$  for a real symmetric matrix  $A$ . Unlike the Conjugate Gradient method,  $A$  can be indefinite or singular.

If  $\text{shift} \neq 0$  then the method solves  $(A - \text{shift}*I)x = b$

- Parameters**
  - A** : {sparse matrix, dense matrix, LinearOperator}
    - The real symmetric N-by-N matrix of the linear system
  - b** : {array, matrix}
    - Right hand side of the linear system. Has shape (N,) or (N,1).
- Returns**
  - x** : {array, matrix}
    - The converged solution.
  - info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

- x0** : {array, matrix}
  - Starting guess for the solution.
- tol** : float
  - Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- maxiter** : integer
  - Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

### Notes

THIS FUNCTION IS EXPERIMENTAL AND SUBJECT TO CHANGE!

`scipy.sparse.linalg.qmr(A, b, x0=None, tol=1e-05, maxiter=None, M1=None, M2=None, callback=None)`

Use Quasi-Minimal Residual iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real-valued N-by-N matrix of the linear system. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).  
The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

### Other Parameters

**x0** : {array, matrix}

Starting guess for the solution.

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M1** : {sparse matrix, dense matrix, LinearOperator}

Left preconditioner for A.

**M2** : {sparse matrix, dense matrix, LinearOperator}

Right preconditioner for A. Used together with the left preconditioner M1. The matrix  $M1 * A * M2$  should have better conditioned than A alone.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

*LinearOperator*

*Examples*

```

>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import qmr
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = qmr(A, b)
>>> print(exitCode)           # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True

```

`scipy.sparse.linalg.gcrotnk` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=1000*, *M=None*, *callback=None*, *m=20*, *k=None*, *CU=None*, *discard\_C=False*, *truncate='oldest'*)

Solve a matrix equation using flexible GCROT(m,k) algorithm.

**Parameters**

- A** : {sparse matrix, dense matrix, LinearOperator}
  - The real or complex N-by-N matrix of the linear system.
- b** : {array, matrix}
  - Right hand side of the linear system. Has shape (N,) or (N,1).
- x0** : {array, matrix}
  - Starting guess for the solution.
- tol** : float, optional
  - Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- maxiter** : int, optional
  - Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}, optional
  - Preconditioner for A. The preconditioner should approximate the inverse of A. gcrotnk is a ‘flexible’ algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** : function, optional
  - User-supplied function to call after each iteration. It is called as `callback(xk)`, where *xk* is the current solution vector.
- m** : int, optional
  - Number of inner FGMRES iterations per each outer iteration. Default: 20
- k** : int, optional
  - Number of vectors to carry between inner FGMRES iterations. According to [R26], good values are around *m*. Default: *m*
- CU** : list of tuples, optional
  - List of tuples (*c*, *u*) which contain the columns of the matrices C and U in the GCROT(m,k) algorithm. For details, see [R26]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The *c* elements in the tuples can be None, in which case the vectors are recomputed via  $c = A u$  on start and orthogonalized as described in [R27].
- discard\_C** : bool, optional
  - Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.
- truncate** : {‘oldest’, ‘smallest’}, optional
  - Truncation scheme to use. Drop: oldest vectors, or vectors with smallest singular values using the scheme discussed in [1,2]. See [R26] for detailed comparison. Default: ‘oldest’

**Returns**

**x** : array or matrix  
The solution found.

**info** : int  
Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations

Iterative methods for least-squares problems:

<code>lsqr(A, b[, damp, atol, btol, conlim, ...])</code>	Find the least-squares solution to a large, sparse, linear system of equations.
<code>lsmr(A, b[, damp, atol, btol, conlim, ...])</code>	Iterative solver for least-squares problems.

`scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-08, btol=1e-08, conlim=100000000.0, iter_lim=None, show=False, calc_var=False, x0=None)`

Find the least-squares solution to a large, sparse, linear system of equations.

The function solves  $Ax = b$  or  $\min ||b - Ax||^2$  or  $\min ||Ax - b||^2 + d^2 ||x||^2$ .

The matrix  $A$  may be square or rectangular (over-determined or under-determined), and may have any rank.

```

1. Unsymmetric equations -- solve A*x = b
2. Linear least squares -- solve A*x = b
                           in the least-squares sense
3. Damped least squares -- solve ( A ) * x = ( b )
                           ( damp*I ) ( 0 )
                           in the least-squares sense

```

**Parameters**

**A** : {sparse matrix, ndarray, LinearOperator}  
Representation of an m-by-n matrix. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

**b** : array\_like, shape (m,)   
Right-hand side vector  $b$ .

**damp** : float   
Damping coefficient.

**atol, btol** : float, optional   
Stopping tolerances. If both are  $1.0e-9$  (say), the final residual norm should be accurate to about 9 digits. (The final  $x$  will usually have fewer correct digits, depending on  $\text{cond}(A)$  and the size of  $\text{damp}$ .)

**conlim** : float, optional   
Another stopping tolerance. `lsqr` terminates if an estimate of  $\text{cond}(A)$  exceeds `conlim`. For compatible systems  $Ax = b$ , `conlim` could be as large as  $1.0e+12$  (say). For least-squares problems, `conlim` should be less than  $1.0e+8$ . Maximum precision can be obtained by setting `atol = btol = conlim = zero`, but the number of iterations may then be excessive.

**iter\_lim** : int, optional   
Explicit limitation on number of iterations (for safety).

**show** : bool, optional   
Display an iteration log.

**calc\_var** : bool, optional  
Whether to estimate diagonals of  $(A'A + \text{damp}^2 * I)^{-1}$ .

**x0** : array\_like, shape (n,), optional  
Initial guess of x, if None zeros are used.  
New in version 1.0.0.

**Returns** **x** : ndarray of float  
The final solution.

**istop** : int  
Gives the reason for termination. 1 means x is an approximate solution to  $Ax = b$ . 2 means x approximately solves the least-squares problem.

**itn** : int  
Iteration number upon termination.

**r1norm** : float  
 $\text{norm}(r)$ , where  $r = b - Ax$ .

**r2norm** : float  
 $\sqrt{\text{norm}(r)^2 + \text{damp}^2 * \text{norm}(x)^2}$ . Equal to *r1norm* if  $\text{damp} == 0$ .

**anorm** : float  
Estimate of Frobenius norm of  $Abar = \begin{bmatrix} A \\ \text{damp} * I \end{bmatrix}$ .

**acond** : float  
Estimate of  $\text{cond}(Abar)$ .

**arnorm** : float  
Estimate of  $\text{norm}(A' * r - \text{damp}^2 * x)$ .

**xnorm** : float  
 $\text{norm}(x)$

**var** : ndarray of float  
If **calc\_var** is True, estimates all diagonals of  $(A'A)^{-1}$  (if  $\text{damp} == 0$ ) or more generally  $(A'A + \text{damp}^2 * I)^{-1}$ . This is well defined if A has full column rank or  $\text{damp} > 0$ . (Not sure what var means if  $\text{rank}(A) < n$  and  $\text{damp} = 0$ .)

### Notes

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of A should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of A is very small or large compared to the other rows of A, the corresponding row of  $(A \ b)$  should be scaled up or down.

In problems 1 and 2, the solution x is easily recovered following column-scaling. Unless better information is known, the nonzero columns of A should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if damp is nonzero. However, the value of damp should be assigned only after attention has been paid to the scaling of A.

The parameter damp is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter acond, which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate x0 is known and if  $\text{damp} == 0$ , one could proceed as follows:

1. Compute a residual vector  $r0 = b - A * x0$ .
2. Use LSQR to solve the system  $A * dx = r0$ .
3. Add the correction dx to obtain a final solution  $x = x0 + dx$ .

This requires that x0 be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes k1 iterations to solve  $A * x = b$  and k2 iterations to solve  $A * dx = r0$ . If x0 is "good",  $\text{norm}(r0)$  will be smaller than  $\text{norm}(b)$ . If the same stopping tolerances atol and btol are used for each system, k1 and k2 will be

similar, but the final solution  $x_0 + dx$  should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value  $btol$  is suitable for  $A*x = b$ , the larger value  $btol*norm(b)/norm(r_0)$  should be suitable for  $A*dx = r_0$ .

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system  $M*x = b$  efficiently, where  $M$  approximates  $A$  in some helpful way (e.g.  $M - A$  has low rank or its elements are small relative to those of  $A$ ), LSQR may converge more rapidly on the system  $A*(inverse)*z = b$ , after which  $x$  can be recovered by solving  $M*x = z$ .

If  $A$  is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (`cg`) and/or `SYMMLQ`. `SYMMLQ` is an implementation of symmetric `cg` that applies to any symmetric  $A$  and will converge more rapidly than LSQR. If  $A$  is positive definite, there are other implementations of symmetric `cg` that require slightly less work per iteration than `SYMMLQ` (but will take the same number of iterations).

### References

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution  $[0, 0]$

```
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
The exact solution is x = 0
>>> istop
0
>>> x
array([ 0.,  0.]
```

The stopping code `istop=0` returned indicates that a vector of zeros was found as a solution. The returned solution  $x$  indeed contains  $[0, 0]$ . The next example has a non-trivial solution:

```
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, rlnorm = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> rlnorm
4.440892098500627e-16
```

As indicated by `istop=1`, `lsqr` found a solution obeying the tolerance limits. The given solution  $[1., -1.]$  obviously solves the equation. The remaining return values include information about the number of iterations (`itn=1`) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, rlnorm = lsqr(A, b)[:4]
>>> istop
2
```

```

>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333,  0.00333333])
>>> rlnorm
0.005773502691896255
    
```

*istop* indicates that the system is inconsistent and thus *x* is rather an approximate solution to the corresponding least-squares problem. *rlnorm* contains the norm of the minimal residual that was found.

`scipy.sparse.linalg.lsmr(A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=100000000.0, maxiter=None, show=False, x0=None)`  
 Iterative solver for least-squares problems.

`lsmr` solves the system of linear equations  $Ax = b$ . If the system is inconsistent, it solves the least-squares problem  $\min \|b - Ax\|_2$ . *A* is a rectangular matrix of dimension *m*-by-*n*, where all cases are allowed:  $m = n$ ,  $m > n$ , or  $m < n$ . *B* is a vector of length *m*. The matrix *A* may be dense or sparse (usually sparse).

**Parameters** *A* : {matrix, sparse matrix, ndarray, LinearOperator}

Matrix *A* in the linear system.

**b** : array\_like, shape (*m*,)

Vector *b* in the linear system.

**damp** : float

Damping factor for regularized least-squares. `lsmr` solves the regularized least-squares problem:

$$\min \left\| \begin{pmatrix} b - Ax \\ 0 \end{pmatrix} \right\|_2$$

where *damp* is a scalar. If *damp* is `None` or 0, the system is solved without regularization.

**atol, btol** : float, optional

Stopping tolerances. `lsmr` continues iterations until a certain backward error estimate is smaller than some quantity depending on *atol* and *btol*. Let  $r = b - Ax$  be the residual vector for the current approximate solution *x*. If  $Ax = b$  seems to be consistent, `lsmr` terminates when  $\text{norm}(r) \leq \text{atol} * \text{norm}(A) * \text{norm}(x) + \text{btol} * \text{norm}(b)$ . Otherwise, `lsmr` terminates when  $\text{norm}(A^T r) \leq \text{atol} * \text{norm}(A) * \text{norm}(r)$ . If both tolerances are 1.0e-6 (say), the final  $\text{norm}(r)$  should be accurate to about 6 digits. (The final *x* will usually have fewer correct digits, depending on  $\text{cond}(A)$  and the size of `LAMBDA`.) If *atol* or *btol* is `None`, a default value of 1.0e-6 will be used. Ideally, they should be estimates of the relative error in the entries of *A* and *B* respectively. For example, if the entries of *A* have 7 correct digits, set *atol* = 1e-7. This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

**conlim** : float, optional

`lsmr` terminates if an estimate of  $\text{cond}(A)$  exceeds *conlim*. For compatible systems  $Ax = b$ , *conlim* could be as large as 1.0e+12 (say). For least-squares problems, *conlim* should be less than 1.0e+8. If *conlim* is `None`, the default value is 1e+8. Maximum precision can be obtained by setting *atol* = *btol* = *conlim* = 0, but the number of iterations may then be excessive.

**maxiter** : int, optional

`lsmr` terminates if the number of iterations reaches *maxiter*. The default is *maxiter* =  $\min(m, n)$ . For ill-conditioned systems, a larger value of

*maxiter* may be needed.

**show** : bool, optional

Print iterations logs if show=True.

**x0** : array\_like, shape (n,), optional

Initial guess of x, if None zeros are used.

New in version 1.0.0.

### Returns

**x** : ndarray of float

Least-square solution returned.

**istop** : int

istop gives the reason for stopping:

```

istop   = 0 means x=0 is a solution.  If x0 was given,
↳then x=x0 is a
        solution.
        = 1 means x is an approximate solution to A*x
↳= B,
        according to atol and btol.
        = 2 means x approximately solves the least-
↳squares problem
        according to atol.
        = 3 means COND(A) seems to be greater than
↳CONLIM.
        = 4 is the same as 1 with atol = btol = eps
↳(machine
        precision)
        = 5 is the same as 2 with atol = eps.
        = 6 is the same as 3 with CONLIM = 1/eps.
        = 7 means ITN reached maxiter before the other
↳stopping
        conditions were satisfied.

```

**itn** : int

Number of iterations used.

**normr** : float

$\text{norm}(b - Ax)$

**normar** : float

$\text{norm}(A^T (b - Ax))$

**norma** : float

$\text{norm}(A)$

**conda** : float

Condition number of A.

**normx** : float

$\text{norm}(x)$

### Notes

New in version 0.11.0.

### References

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution  $[0, 0]$

```
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
0
>>> x
array([ 0.,  0.]
```

The stopping code  $istop=0$  returned indicates that a vector of zeros was found as a solution. The returned solution  $x$  indeed contains  $[0, 0]$ . The next example has a non-trivial solution:

```
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> normr
4.440892098500627e-16
```

As indicated by  $istop=1$ ,  $lsqr$  found a solution obeying the tolerance limits. The given solution  $[1, -1]$  obviously solves the equation. The remaining return values include information about the number of iterations ( $itn=1$ ) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333,  0.00333333])
>>> normr
0.005773502691896255
```

$istop$  indicates that the system is inconsistent and thus  $x$  is rather an approximate solution to the corresponding least-squares problem.  $normr$  contains the minimal distance that was found.

## Matrix factorizations

Eigenvalue problems:

`eigs(A[, k, M, sigma, which, v0, nc, ...])`

Find  $k$  eigenvalues and eigenvectors of the square matrix  $A$ .

`eigsh(A[, k, M, sigma, which, v0, nc, ...])`

Find  $k$  eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix  $A$ .

Continued on next page

Table 5.195 – continued from previous page

<code>lobpcg(A, X[, B, M, Y, tol, maxiter, ...])</code>	Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)
---	---

`scipy.sparse.linalg.eigs` (*A*, *k*=6, *M*=None, *sigma*=None, *which*='LM', *v0*=None, *ncv*=None, *maxiter*=None, *tol*=0, *return\_eigenvectors*=True, *Minv*=None, *OPinv*=None, *OPpart*=None)

Find *k* eigenvalues and eigenvectors of the square matrix *A*.

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for *w*[*i*] eigenvalues with corresponding eigenvectors *x*[*i*].

If *M* is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for *w*[*i*] eigenvalues with corresponding eigenvectors *x*[*i*]

**Parameters** *A* : ndarray, sparse matrix or LinearOperator

An array, sparse matrix, or LinearOperator representing the operation  $A * x$ , where *A* is a real or complex square matrix.

*k* : int, optional

The number of eigenvalues and eigenvectors desired. *k* must be smaller than *N*-1. It is not possible to compute all eigenvectors of a matrix.

*M* : ndarray, sparse matrix or LinearOperator, optional

An array, sparse matrix, or LinearOperator representing the operation  $M * x$  for the generalized eigenvalue problem

$$A * x = w * M * x.$$

*M* must represent a real, symmetric matrix if *A* is real, and must represent a complex, hermitian matrix if *A* is complex. For best results, the data type of *M* should be the same as that of *A*. Additionally:

If *sigma* is None, *M* is positive definite

If *sigma* is specified, *M* is positive semi-definite

If *sigma* is None, `eigs` requires an operator to compute the solution of the linear equation  $M * x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix *M*, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator *Minv*, which gives  $x = Minv * b = M^{-1} * b$ .

*sigma* : real or complex, optional

Find eigenvalues near *sigma* using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - sigma * M] * x = b$ , where *M* is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices *A* & *M*, or via an iterative solver if either *A* or *M* is a general linear operator. Alternatively, the user can supply the matrix or operator *OPinv*, which gives  $x = OPinv * b = [A - sigma * M]^{-1} * b$ . For a real matrix *A*, shift-invert can either be done in imaginary mode or real mode, specified by the parameter *OPpart* ('r' or 'i'). Note that when *sigma* is specified, the keyword 'which' (below) refers to the shifted eigenvalues *w*' [*i*] where:

**If *A* is real and *OPpart* == 'r' (default),**

$$w'[i] = 1/2 * [1/(w[i]-sigma) + 1/(w[i]-conj(sigma))].$$

**If *A* is real and *OPpart* == 'i',**

$$w'[i] = 1/2i * [1/(w[i]-sigma) - 1/(w[i]-conj(sigma))].$$

If *A* is complex,  $w'[i] = 1/(w[i]-sigma)$ .

*v0* : ndarray, optional

Starting vector for iteration. Default: random

**ncv** : int, optional  
 The number of Lanczos vectors generated *ncv* must be greater than *k*; it is recommended that  $ncv > 2*k$ . Default:  $\min(n, \max(2*k + 1, 20))$

**which** : str, ['LM' | 'SM' | 'LR' | 'SR' | 'LI' | 'SI'], optional  
 Which *k* eigenvectors and eigenvalues to find:  
     'LM' : largest magnitude  
     'SM' : smallest magnitude  
     'LR' : largest real part  
     'SR' : smallest real part  
     'LI' : largest imaginary part  
     'SI' : smallest imaginary part

When *sigma* != None, 'which' refers to the shifted eigenvalues *w*'[i] (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** : int, optional  
 Maximum number of Arnoldi update iterations allowed Default:  $n*10$

**tol** : float, optional  
 Relative accuracy for eigenvalues (stopping criterion) The default value of 0 implies machine precision.

**return\_eigenvectors** : bool, optional  
 Return eigenvectors (True) in addition to eigenvalues

**Minv** : ndarray, sparse matrix or LinearOperator, optional  
 See notes in *M*, above.

**OPinv** : ndarray, sparse matrix or LinearOperator, optional  
 See notes in *sigma*, above.

**OPpart** : {'r' or 'i'}, optional  
 See notes in *sigma*, above

**Returns**

**w** : ndarray  
 Array of *k* eigenvalues.

**v** : ndarray  
 An array of *k* eigenvectors.  $v[:, i]$  is the eigenvector corresponding to the eigenvalue  $w[i]$ .

**Raises**

**ArpackNoConvergence**  
 When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as *eigenvalues* and *eigenvectors* attributes of the exception object.

**See also:**

**eigsh** eigenvalues and eigenvectors for symmetric matrix *A*  
**svds** singular value decomposition for a matrix *A*

**Notes**

This function is a wrapper to the ARPACK [R18] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [R19].

**References**

[R18], [R19]

**Examples**

Find 6 eigenvectors of the identity matrix:

```

>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigs(id, k=6)
>>> vals
array([ 1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j])
>>> vecs.shape
(13, 6)

```

`scipy.sparse.linalg.eigsh`(*A*, *k*=6, *M*=None, *sigma*=None, *which*='LM', *v0*=None, *ncv*=None, *maxiter*=None, *tol*=0, *return\_eigenvectors*=True, *Minv*=None, *OPinv*=None, *mode*='normal')

Find *k* eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix *A*.

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for *w*[*i*] eigenvalues with corresponding eigenvectors *x*[*i*].

If *M* is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for *w*[*i*] eigenvalues with corresponding eigenvectors *x*[*i*]

**Parameters** *A* : An *N* x *N* matrix, array, sparse matrix, or LinearOperator representing the operation  $A * x$ , where *A* is a real symmetric matrix For buckling mode (see below) *A* must additionally be positive-definite

*k* : int, optional  
The number of eigenvalues and eigenvectors desired. *k* must be smaller than *N*. It is not possible to compute all eigenvectors of a matrix.

**Returns** *w* : array  
Array of *k* eigenvalues

*v* : array  
An array representing the *k* eigenvectors. The column *v*[:, *i*] is the eigenvector corresponding to the eigenvalue *w*[*i*].

**Other Parameters**

*M* : An *N* x *N* matrix, array, sparse matrix, or linear operator representing the operation  $M * x$  for the generalized eigenvalue problem  
 $A * x = w * M * x$ .

*M* must represent a real, symmetric matrix if *A* is real, and must represent a complex, hermitian matrix if *A* is complex. For best results, the data type of *M* should be the same as that of *A*. Additionally:

If *sigma* is None, *M* is symmetric positive definite  
If *sigma* is specified, *M* is symmetric positive semi-definite  
In buckling mode, *M* is symmetric indefinite.

If *sigma* is None, `eigsh` requires an operator to compute the solution of the linear equation  $M * x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix *M*, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator *Minv*, which gives  $x = Minv * b = M^{-1} * b$ .

*sigma* : real

Find eigenvalues near *sigma* using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - sigma * M] x = b$ , where *M* is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices *A* & *M*, or via an iterative solver if either *A* or *M* is a general linear operator. Alternatively, the user can supply the matrix or operator *OPinv*, which gives  $x = OPinv * b = [A - sigma * M]^{-1} * b$ . Note that when *sigma* is specified, the keyword 'which' refers to the shifted eigenvalues *w*' [*i*] where:

if *mode* == 'normal',  $w'[i] = 1 / (w[i] - sigma)$ .

```

if mode == 'cayley', w'[i] = (w[i] + sigma) /
(w[i] - sigma).
if mode == 'buckling', w'[i] = w[i] / (w[i] -
sigma).

```

(see further discussion in 'mode' below)

**v0** : ndarray, optional

Starting vector for iteration. Default: random

**ncv** : int, optional

The number of Lanczos vectors generated ncv must be greater than k and smaller than n; it is recommended that  $ncv > 2*k$ . Default:  $\min(n, \max(2*k + 1, 20))$

**which** : str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']

If A is a complex hermitian matrix, 'BE' is invalid. Which k eigenvectors and eigenvalues to find:

```

'LM' : Largest (in magnitude) eigenvalues
'SM' : Smallest (in magnitude) eigenvalues
'LA' : Largest (algebraic) eigenvalues
'SA' : Smallest (algebraic) eigenvalues
'BE' : Half (k/2) from each end of the spectrum

```

When k is odd, return one more (k/2+1) from the high end. When sigma != None, 'which' refers to the shifted eigenvalues w'[i] (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** : int, optional

Maximum number of Arnoldi update iterations allowed Default: n\*10

**tol** : float

Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

**Minv** : N x N matrix, array, sparse matrix, or LinearOperator

See notes in M, above

**OPinv** : N x N matrix, array, sparse matrix, or LinearOperator

See notes in sigma, above.

**return\_eigenvectors** : bool

Return eigenvectors (True) in addition to eigenvalues

**mode** : string ['normal' | 'buckling' | 'cayley']

Specify strategy to use for shift-invert mode. This argument applies only for real-valued A and sigma != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem  $OP * x'[i] = w'[i] * B * x'[i]$  and transforms the resulting Ritz vectors x'[i] and Ritz values w'[i] into the desired eigenvectors and eigenvalues of the problem  $A * x[i] = w[i] * M * x[i]$ . The modes are as follows:

```

'normal' :   OP = [A - sigma * M]^(-1) * M, B = M, w'[i]
             = 1 / (w[i] - sigma)
'buckling' : OP = [A - sigma * M]^(-1) * A, B = A, w'[i] =
             w[i] / (w[i] - sigma)
'cayley' :   OP = [A - sigma * M]^(-1) * [A + sigma * M],
             B = M, w'[i] = (w[i] + sigma) / (w[i] - sigma)

```

The choice of mode will affect which eigenvalues are selected by the keyword 'which', and can also impact the stability of convergence (see [2] for a discussion)

**Raises**

**ArpackNoConvergence**

When the requested convergence is not obtained.

The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

**See also:**

**eigs** eigenvalues and eigenvectors for a general (nonsymmetric) matrix A  
**svds** singular value decomposition for a matrix A

**Notes**

This function is a wrapper to the ARPACK [R20] SSEUPD and DSEUPD functions which use the Implicitly Restarted Lanczos Method to find the eigenvalues and eigenvectors [R21].

`scipy.sparse.linalg.lobpcg(A, X, B=None, M=None, Y=None, tol=None, maxiter=20, largest=True, verbosityLevel=0, retLambdaHistory=False, retResidualNormsHistory=False)`

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

**Parameters**

- A** : {sparse matrix, dense matrix, LinearOperator}  
The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.
- X** : array\_like  
Initial approximation to the k eigenvectors. If A has shape=(n,n) then X should have shape shape=(n,k).
- B** : {dense matrix, sparse matrix, LinearOperator}, optional  
the right hand side operator in a generalized eigenproblem. by default, B = Identity often called the “mass matrix”
- M** : {dense matrix, sparse matrix, LinearOperator}, optional  
preconditioner to A; by default M = Identity M should approximate the inverse of A
- Y** : array\_like, optional  
n-by-sizeY matrix of constraints, sizeY < n The iterations will be performed in the B-orthogonal complement of the column-space of Y. Y must be full rank.

**Returns**

- w** : array  
Array of k eigenvalues
- v** : array  
An array of k eigenvectors. V has the same shape as X.

**Other Parameters**

- tol** : scalar, optional  
Solver tolerance (stopping criterion) by default: `tol=n*sqrt(eps)`
- maxiter** : integer, optional

maximum number of iterations by default: `maxiter=min(n,20)`  
**largest** : bool, optional  
 when True, solve for the largest eigenvalues, otherwise the smallest  
**verbosityLevel** : integer, optional  
 controls solver output. default: `verbosityLevel = 0`.  
**retLambdaHistory** : boolean, optional  
 whether to return eigenvalue history  
**retResidualNormsHistory** : boolean, optional  
 whether to return history of residual norms

*Notes*

If both `retLambdaHistory` and `retResidualNormsHistory` are True, the return tuple has the following format (lambda, V, lambda history, residual norms history).

In the following `n` denotes the matrix size and `m` the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size  $3 \times m$  on every iteration by calling the “standard” dense eigensolver, so if `m` is not small enough compared to `n`, it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. `numpy` or `scipy` function in this case. If one calls the LOBPCG algorithm for  $5 \times m > n$ , it will most likely break internally, so the code tries to call the standard function instead.

It is not that `n` should be large for the LOBPCG to work, but rather the ratio `n/m` should be large. If you call the LOBPCG code with `m=1` and `n=10`, it should work, though `n` is small. The method is intended for extremely large `n/m`, see e.g., reference [28] in <http://arxiv.org/abs/0705.2626>

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary `m` to make this better.
2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large `n`, so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for `A`, which is easy to code since `A` is tridiagonal.

*Acknowledgements*

`lobpcg.py` code was written by Robert Cimrman. Many thanks belong to Andrew Knyazev, the author of the algorithm, for lots of advice and support.

*Examples*

Solve  $Ax = \lambda Bx$  with constraints and preconditioning.

```
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = [np.arange(n, dtype=np.float64) + 1]
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1.,  0.,  0., ...,  0.,  0.,  0.],
       [ 0.,  2.,  0., ...,  0.,  0.,  0.],
       [ 0.,  0.,  3., ...,  0.,  0.,  0.],
       ...,
       [ 0.,  0.,  0., ..., 98.,  0.,  0.]])
```

```
[ 0., 0., 0., ..., 0., 99., 0.],
 [ 0., 0., 0., ..., 0., 0., 100.]])
```

Constraints.

```
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```
>>> X = np.random.rand(n, 3)
```

Preconditioner – inverse of A (as an abstract linear operator).

```
>>> invA = spdiags([1./vals[0]], 0, n, n)
>>> def precondition(x):
...     return invA * x
>>> M = LinearOperator(matvec=precond, shape=(n, n), dtype=float)
```

Here, `invA` could of course have been used directly as a preconditioner. Let us then solve the problem:

```
>>> eigs, vecs = lobpcg(A, X, Y=Y, M=M, tol=1e-4, maxiter=40, largest=False)
>>> eigs
array([ 4., 5., 6.])
```

Note that the vectors passed in `Y` are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

`svds(A[, k, ncv, tol, which, v0, maxiter, ...])`

Compute the largest  $k$  singular values/vectors for a sparse matrix.

`scipy.sparse.linalg.svds(A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return_singular_vectors=True)`

Compute the largest  $k$  singular values/vectors for a sparse matrix.

**Parameters** **A** : {sparse matrix, LinearOperator}

Array to compute the SVD on, of shape (M, N)

**k** : int, optional

Number of singular values and vectors to compute. Must be  $1 \leq k < \min(A.shape)$ .

**ncv** : int, optional

The number of Lanczos vectors generated `ncv` must be greater than  $k+1$  and smaller than  $n$ ; it is recommended that `ncv`  $> 2*k$  Default:  $\min(n, \max(2*k + 1, 20))$

**tol** : float, optional

Tolerance for singular values. Zero (default) means machine precision.

**which** : str, ['LM' | 'SM'], optional

Which  $k$  singular values to find:

- 'LM' : largest singular values
- 'SM' : smallest singular values

New in version 0.12.0.

**v0** : ndarray, optional

Starting vector for iteration, of length  $\min(A.shape)$ . Should be an (approximate) left singular vector if  $N > M$  and a right singular vector otherwise.

Default: random  
 New in version 0.12.0.

**maxiter** : int, optional  
 Maximum number of iterations.  
 New in version 0.12.0.

**return\_singular\_vectors** : bool or str, optional

- True: return singular vectors (True) in addition to singular values.

New in version 0.12.0.

- "u": only return the u matrix, without computing vh (if  $N > M$ ).
- "vh": only return the vh matrix, without computing u (if  $N \leq M$ ).

**Returns**

**u** : ndarray, shape=(M, k)  
 New in version 0.16.0.  
 Unitary matrix having left singular vectors as columns. If *return\_singular\_vectors* is "vh", this variable is not computed, and None is returned instead.

**s** : ndarray, shape=(k,)  
 The singular values.

**vt** : ndarray, shape=(k, N)  
 Unitary matrix having right singular vectors as rows. If *return\_singular\_vectors* is "u", this variable is not computed, and None is returned instead.

**Notes**

This is a naive implementation using ARPACK as an eigensolver on  $A.H * A$  or  $A * A.H$ , depending on which one is more efficient.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import svds, eigs
>>> A = csc_matrix([[1, 0, 0], [5, 0, 2], [0, -1, 0], [0, 0, 3]], dtype=float)
>>> u, s, vt = svds(A, k=2)
>>> s
array([ 2.75193379,  5.6059665 ])
>>> np.sqrt(eigs(A.dot(A.T), k=2)[0]).real
array([ 5.6059665 ,  2.75193379])
```

Complete or incomplete LU factorizations

<code>splu(A[, permc_spec, diag_pivot_thresh, ...])</code>	Compute the LU decomposition of a sparse, square matrix.
<code>spilu(A[, drop_tol, fill_factor, drop_rule, ...])</code>	Compute an incomplete LU decomposition for a sparse, square matrix.
<i>SuperLU</i>	LU factorization of a sparse matrix.

`scipy.sparse.linalg.splu(A, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options={})`  
 Compute the LU decomposition of a sparse, square matrix.

**Parameters**

**A** : sparse matrix  
 Sparse matrix to factorize. Should be in CSR or CSC format.

**permc\_spec** : str, optional  
 How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')

- **NATURAL**: natural ordering.
- **MMD\_ATA**: minimum degree ordering on the structure of  $A^T A$ .
- **MMD\_AT\_PLUS\_A**: minimum degree ordering on the structure of  $A^T A + A$ .
- **COLAMD**: approximate minimum degree column ordering

**diag\_pivot\_thresh** : float, optional

Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user's guide for details [R43]

**relax** : int, optional

Expert option for customizing the degree of relaxing supernodes. See SuperLU user's guide for details [R43]

**panel\_size** : int, optional

Expert option for customizing the panel size. See SuperLU user's guide for details [R43]

**options** : dict, optional

Dictionary containing additional expert options to SuperLU. See SuperLU user guide [R43] (section 2.4 on the 'Options' argument) for more details. For example, you can specify `options=dict(Equil=False, IterRefine='SINGLE')` to turn equilibration off and perform a single iterative refinement.

**Returns** **invA** : `scipy.sparse.linalg.SuperLU` Object, which has a `solve` method.

**See also:**

**spilu** incomplete LU decomposition

**Notes**

This function uses the SuperLU library.

**References**

[R43]

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]], dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1.,  2.,  3.])
>>> B.solve(A.dot(x))
array([ 1.,  2.,  3.])
```

`scipy.sparse.linalg.spilu`(*A*, *drop\_tol*=None, *fill\_factor*=None, *drop\_rule*=None, *permc\_spec*=None, *diag\_pivot\_thresh*=None, *relax*=None, *panel\_size*=None, *options*=None)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of *A*.

**Parameters** **A** : (N, N) array\_like  
Sparse matrix to factorize  
**drop\_tol** : float, optional

Drop tolerance ( $0 \leq \text{tol} \leq 1$ ) for an incomplete LU decomposition. (default:  $1e-4$ )

**fill\_factor** : float, optional

Specifies the fill ratio upper bound ( $\geq 1.0$ ) for ILU. (default: 10)

**drop\_rule** : str, optional

Comma-separated string of drop rules to use. Available rules: `basic`, `prows`, `column`, `area`, `secondary`, `dynamic`, `interp`. (Default: `basic, area`)

See SuperLU documentation for details.

**Remaining other options**

**Returns** **invA\_approx** : Same as for `splu`, `scipy.sparse.linalg.SuperLU` Object, which has a `solve` method.

**See also:**

**splu** complete LU decomposition

**Notes**

To improve the better approximation to the inverse, you may need to increase `fill_factor` AND decrease `drop_tol`.

This function uses the SuperLU library.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]], dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1.,  2.,  3.])
>>> B.solve(A.dot(x))
array([ 1.,  2.,  3.])
```

**class** `scipy.sparse.linalg.SuperLU`

LU factorization of a sparse matrix.

Factorization is represented as:

$$P_r * A * P_c = L * U$$

To construct these *SuperLU* objects, call the `splu` and `spilu` functions.

**Notes**

New in version 0.14.0.

**Examples**

The LU decomposition can be used to solve matrix equations. Consider:

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1,2,0,4],[1,0,0,1],[1,0,2,1],[2,2,1,0]])
```

This can be solved for a given right-hand side:

```

>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([ 1.,  2.,  3.,  4.])

```

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```

>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)

```

The `L` and `U` factors are sparse matrices in `CSC` format:

```

>>> lu.L.A
array([[ 1.,  0.,  0.,  0.],
       [ 0.,  1.,  0.,  0.],
       [ 0.,  0.,  1.,  0.],
       [ 1.,  0.5,  0.5,  1.]])
>>> lu.U.A
array([[ 2.,  0.,  1.,  4.],
       [ 0.,  2.,  1.,  1.],
       [ 0.,  0.,  1.,  1.],
       [ 0.,  0.,  0., -5.]])

```

The permutation matrices can be constructed:

```

>>> Pr = csc_matrix((4, 4))
>>> Pr[lu.perm_r, np.arange(4)] = 1
>>> Pc = csc_matrix((4, 4))
>>> Pc[np.arange(4), lu.perm_c] = 1

```

We can reassemble the original matrix:

```

>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1.,  2.,  0.,  4.],
       [ 1.,  0.,  0.,  1.],
       [ 1.,  0.,  2.,  1.],
       [ 2.,  2.,  1.,  0.]])

```

### Attributes

<code>shape</code>	Shape of the original matrix as a tuple of ints.
<code>nnz</code>	Number of nonzero elements in the matrix.
<code>perm_c</code>	Permutation <code>Pc</code> represented as an array of indices.
<code>perm_r</code>	Permutation <code>Pr</code> represented as an array of indices.
<code>L</code>	Lower triangular factor with unit diagonal as a <code>scipy.sparse.csc_matrix</code> .
<code>U</code>	Upper triangular factor as a <code>scipy.sparse.csc_matrix</code> .

### SuperLU.`shape`

Shape of the original matrix as a tuple of ints.

*Attributes*

eigenvalues	(ndarray) Partial result. Converged eigenvalues.
eigenvectors	(ndarray) Partial result. Converged eigenvectors.

**Functions**

<i>aslinearoperator</i> (A)	Return A as a LinearOperator.
<i>bicg</i> (A, b[, x0, tol, maxiter, M, callback])	Use BIConjugate Gradient iteration to solve $Ax = b$ .
<i>bicgstab</i> (A, b[, x0, tol, maxiter, M, callback])	Use BIConjugate Gradient STABILized iteration to solve $Ax = b$ .
<i>cg</i> (A, b[, x0, tol, maxiter, M, callback])	Use Conjugate Gradient iteration to solve $Ax = b$ .
<i>cgs</i> (A, b[, x0, tol, maxiter, M, callback])	Use Conjugate Gradient Squared iteration to solve $Ax = b$ .
<i>eigs</i> (A[, k, M, sigma, which, v0, ncv, ...])	Find k eigenvalues and eigenvectors of the square matrix A.
<i>eigsh</i> (A[, k, M, sigma, which, v0, ncv, ...])	Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix A.
<i>expm</i> (A)	Compute the matrix exponential using Pade approximation.
<i>expm_multiply</i> (A, B[, start, stop, num, endpoint])	Compute the action of the matrix exponential of A on B.
<i>factorized</i> (A)	Return a function for solving a sparse linear system, with A pre-factorized.
<i>gcrotmk</i> (A, b[, x0, tol, maxiter, M, ...])	Solve a matrix equation using flexible GCROT(m,k) algorithm.
<i>gmres</i> (A, b[, x0, tol, restart, maxiter, M, ...])	Use Generalized Minimal RESidual iteration to solve $Ax = b$ .
<i>inv</i> (A)	Compute the inverse of a sparse matrix
<i>lgmres</i> (A, b[, x0, tol, maxiter, M, ...])	Solve a matrix equation using the LGMRES algorithm.
<i>lobpcg</i> (A, X[, B, M, Y, tol, maxiter, ...])	Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)
<i>lsmr</i> (A, b[, damp, atol, btol, conlim, ...])	Iterative solver for least-squares problems.
<i>lsqr</i> (A, b[, damp, atol, btol, conlim, ...])	Find the least-squares solution to a large, sparse, linear system of equations.
<i>minres</i> (A, b[, x0, shift, tol, maxiter, M, ...])	Use MINimum RESidual iteration to solve $Ax=b$
<i>norm</i> (x[, ord, axis])	Norm of a sparse matrix
<i>onenormest</i> (A[, t, itmax, compute_v, compute_w])	Compute a lower bound of the 1-norm of a sparse matrix.
<i>qmr</i> (A, b[, x0, tol, maxiter, M1, M2, callback])	Use Quasi-Minimal Residual iteration to solve $Ax = b$ .
<i>spilu</i> (A[, drop_tol, fill_factor, drop_rule, ...])	Compute an incomplete LU decomposition for a sparse, square matrix.
<i>splu</i> (A[, permc_spec, diag_pivot_thresh, ...])	Compute the LU decomposition of a sparse, square matrix.
<i>spsolve</i> (A, b[, permc_spec, use_umfpack])	Solve the sparse linear system $Ax=b$ , where b may be a vector or a matrix.
<i>spsolve_triangular</i> (A, b[, lower, ...])	Solve the equation $Ax = b$ for x, assuming A is a triangular matrix.
<i>svds</i> (A[, k, ncv, tol, which, v0, maxiter, ...])	Compute the largest k singular values/vectors for a sparse matrix.
<i>use_solver</i> (**kwargs)	Select default sparse direct solver to be used.

**Classes**

<i>LinearOperator</i> (dtype, shape)	Common interface for performing matrix vector products
<i>SuperLU</i>	LU factorization of a sparse matrix.

**Exceptions**

<code>ArpackError(info[, infodict])</code>	ARPACK error
<code>ArpackNoConvergence(msg, eigenvalues, ...)</code>	ARPACK iteration did not converge
<code>MatrixRankWarning</code>

**exception** `scipy.sparse.SparseWarning`

## 5.21.2 Usage information

There are seven available sparse matrix types:

1. `csc_matrix`: Compressed Sparse Column format
2. `csr_matrix`: Compressed Sparse Row format
3. `bsr_matrix`: Block Sparse Row format
4. `lil_matrix`: List of Lists format
5. `dok_matrix`: Dictionary of Keys format
6. `coo_matrix`: COOrdinate format (aka IJV, triplet format)
7. `dia_matrix`: DIAgonal format

To construct a matrix efficiently, use either `dok_matrix` or `lil_matrix`. The `lil_matrix` class supports basic slicing and fancy indexing with a similar syntax to NumPy arrays. As illustrated below, the COO format may also be used to efficiently construct matrices. Despite their similarity to NumPy arrays, it is **strongly discouraged** to use NumPy functions directly on these matrices because NumPy may not properly convert them for computations, leading to unexpected (and incorrect) results. If you do want to apply a NumPy function to these matrices, first check if SciPy has its own implementation for the given sparse matrix class, or **convert the sparse matrix to a NumPy array** (e.g. using the `toarray()` method of the class) first before applying the method.

To perform manipulations such as multiplication or inversion, first convert the matrix to either CSC or CSR format. The `lil_matrix` format is row-based, so conversion to CSR is efficient, whereas conversion to CSC is less so.

All conversions among the CSR, CSC, and COO formats are efficient, linear-time operations.

### Matrix vector product

To do a vector product between a sparse matrix and a vector simply use the matrix `dot` method, as described in its docstring:

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
```

```
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**Warning:** As of NumPy 1.7, *np.dot* is not aware of sparse matrices, therefore using it will result on unexpected results or errors. The corresponding dense array should be obtained first instead:

```
>>> np.dot(A.toarray(), v)
array([ 1, -3, -1], dtype=int64)
```

but then all the performance advantages would be lost.

The CSR format is specially suitable for fast matrix vector products.

### Example 1

Construct a 1000x1000 `lil_matrix` and add some values to it:

```
>>> from scipy.sparse import lil_matrix
>>> from scipy.sparse.linalg import spsolve
>>> from numpy.linalg import solve, norm
>>> from numpy.random import rand
```

```
>>> A = lil_matrix((1000, 1000))
>>> A[0, :100] = rand(100)
>>> A[1, 100:200] = A[0, :100]
>>> A.setdiag(rand(1000))
```

Now convert it to CSR format and solve  $Ax = b$  for  $x$ :

```
>>> A = A.tocsr()
>>> b = rand(1000)
>>> x = spsolve(A, b)
```

Convert it to a dense matrix and solve, and check that the result is the same:

```
>>> x_ = solve(A.toarray(), b)
```

Now we can compute norm of the error with:

```
>>> err = norm(x-x_)
>>> err < 1e-10
True
```

It should be small :)

### Example 2

Construct a matrix in COO format:

```
>>> from scipy import sparse
>>> from numpy import array
>>> I = array([0,3,1,0])
>>> J = array([0,3,1,2])
```

```
>>> V = array([4, 5, 7, 9])
>>> A = sparse.coo_matrix((V, (I, J)), shape=(4, 4))
```

Notice that the indices do not need to be sorted.

Duplicate (i,j) entries are summed when converting to CSR or CSC.

```
>>> I = array([0, 0, 1, 3, 1, 0, 0])
>>> J = array([0, 2, 1, 3, 1, 0, 0])
>>> V = array([1, 1, 1, 1, 1, 1, 1])
>>> B = sparse.coo_matrix((V, (I, J)), shape=(4, 4)).tocsr()
```

This is useful for constructing finite-element stiffness and mass matrices.

### Further Details

CSR column indices are not necessarily sorted. Likewise for CSC row indices. Use the `.sorted_indices()` and `.sort_indices()` methods when sorted indices are required (e.g. when passing data to other libraries).

## 5.22 Sparse linear algebra (`scipy.sparse.linalg`)

### 5.22.1 Abstract linear operators

<code>LinearOperator(dtype, shape)</code>	Common interface for performing matrix vector products
<code>aslinearoperator(A)</code>	Return A as a LinearOperator.

**class** `scipy.sparse.linalg.LinearOperator` (*dtype, shape*)  
 Common interface for performing matrix vector products

Many iterative methods (e.g. `cg`, `gmres`) do not need to know the individual entries of a matrix to solve a linear system  $Ax=b$ . Such solvers only require the computation of matrix vector products,  $A*v$  where  $v$  is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete `LinearOperator`, either pass appropriate callables to the constructor of this class, or subclass it.

A subclass must implement either one of the methods `_matvec` and `_matmat`, and the attributes/properties `shape` (pair of integers) and `dtype` (may be `None`). It may call the `__init__` on this class to have these attributes validated. Implementing `_matvec` automatically implements `_matmat` (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement `_rmatvec` or `_adjoint` to implement the Hermitian adjoint (conjugate transpose). As with `_matvec` and `_matmat`, implementing either `_rmatvec` or `_adjoint` implements the other automatically. Implementing `_adjoint` is preferable; `_rmatvec` is mostly there for backwards compatibility.

- Parameters**
- shape** : tuple  
Matrix dimensions (M,N).
  - matvec** : callable `f(v)`  
Returns returns  $A * v$ .
  - rmatvec** : callable `f(v)`  
Returns  $A^H * v$ , where  $A^H$  is the conjugate transpose of  $A$ .
  - matmat** : callable `f(V)`

Returns  $A * V$ , where  $V$  is a dense matrix with dimensions  $(N,K)$ .

**dtype** : dtype

Data type of the matrix.

**See also:**

**aslinearoperator**

Construct LinearOperators

**Notes**

The user-defined `matvec()` function must properly handle the case where  $v$  has shape  $(N,)$  as well as the  $(N,1)$  case. The shape of the return type is handled internally by `LinearOperator`.

`LinearOperator` instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite `LinearOperator`, that defers linear operations to the original operators and combines the results.

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...     return np.array([2*v[0], 3*v[1]])
...
>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
>>> A.matvec(np.ones(2))
array([ 2.,  3.])
>>> A * np.ones(2)
array([ 2.,  3.])
```

**Attributes**

args	(tuple) For linear operators describing products etc. of other linear operators, the operands of the binary operation.
------	--

**Methods**

<code>__call__(x)</code>	
<code>adjoint()</code>	Hermitian adjoint.
<code>dot(x)</code>	Matrix-matrix or matrix-vector multiplication.
<code>matmat(X)</code>	Matrix-matrix multiplication.
<code>matvec(x)</code>	Matrix-vector multiplication.
<code>rmatvec(x)</code>	Adjoint matrix-vector multiplication.
<code>transpose()</code>	Transpose this linear operator.

`LinearOperator.__call__(x)`

`LinearOperator.adjoint()`

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated `self.H` instead of `self.adjoint()`.

**Returns** **A\_H**: LinearOperator  
Hermitian adjoint of self.

LinearOperator.**dot**(x)

Matrix-matrix or matrix-vector multiplication.

**Parameters** **x**: array\_like

**Returns** **Ax**: array 1-d or 2-d array, representing a vector or matrix.

1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

LinearOperator.**matmat**(X)

Matrix-matrix multiplication.

Performs the operation  $y=A*X$  where A is an  $M \times N$  linear operator and X dense  $N \times K$  matrix or ndarray.

**Parameters** **X**: {matrix, ndarray}

**Returns** **Y**: {matrix, ndarray} An array with shape (N,K).

A matrix or ndarray with shape (M,K) depending on the type of the X argument.

**Notes**

This matmat wraps any user-specified matmat routine or overridden `_matmat` method to ensure that y has the correct type.

LinearOperator.**matvec**(x)

Matrix-vector multiplication.

Performs the operation  $y=A*x$  where A is an  $M \times N$  linear operator and x is a column vector or 1-d array.

**Parameters** **x**: {matrix, ndarray}

**Returns** **y**: {matrix, ndarray} An array with shape (N,) or (N,1).

A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.

**Notes**

This matvec wraps the user-specified matvec routine or overridden `_matvec` method to ensure that y has the correct shape and type.

LinearOperator.**rmatvec**(x)

Adjoint matrix-vector multiplication.

Performs the operation  $y = A^H * x$  where A is an  $M \times N$  linear operator and x is a column vector or 1-d array.

**Parameters** **x**: {matrix, ndarray}

**Returns** **y**: {matrix, ndarray} An array with shape (M,) or (M,1).

A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the x argument.

**Notes**

This rmatvec wraps the user-specified rmatvec routine or overridden `_rmatvec` method to ensure that y has the correct shape and type.

LinearOperator.**transpose**()

Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

`scipy.sparse.linalg.aslinearoperator(A)`

Return A as a LinearOperator.

'A' may be any of the following types:

- ndarray
- matrix
- sparse matrix (e.g. csr\_matrix, lil\_matrix, etc.)
- LinearOperator
- An object with .shape and .matvec attributes

See the LinearOperator documentation for additional information.

### Examples

```
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1,2,3],[4,5,6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

## 5.2.2.2 Matrix Operations

<code>inv(A)</code>	Compute the inverse of a sparse matrix
<code>expm(A)</code>	Compute the matrix exponential using Pade approximation.
<code>expm_multiply(A, B[, start, stop, num, endpoint])</code>	Compute the action of the matrix exponential of A on B.

`scipy.sparse.linalg.inv(A)`

Compute the inverse of a sparse matrix

**Parameters** A : (M,M) ndarray or sparse matrix

**Returns** Ainv : (M,M) ndarray or sparse matrix  
square matrix to be inverted  
inverse of A

### Notes

This computes the sparse inverse of A. If the inverse of A is expected to be non-sparse, it will likely be faster to convert A to dense and use `scipy.linalg.inv`.

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import inv
>>> A = csc_matrix([[1., 0.], [1., 2.]])
>>> Ainv = inv(A)
>>> Ainv
<2x2 sparse matrix of type '<class 'numpy.float64''>'
  with 3 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv)
<2x2 sparse matrix of type '<class 'numpy.float64''>'
  with 2 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv).todense()
matrix([[ 1.,  0.],
        [ 0.,  1.]])
```

New in version 0.12.0.

`scipy.sparse.linalg.expm(A)`

Compute the matrix exponential using Pade approximation.

**Parameters** **A** : (M,M) array\_like or sparse matrix  
**Returns** **expA** : (M,M) ndarray  
 2D Array or Matrix (sparse or dense) to be exponentiated  
 Matrix exponential of A

**Notes**

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

**References**

[R373]

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm
>>> A = csc_matrix([[1, 0, 0], [0, 2, 0], [0, 0, 3]])
>>> A.todense()
matrix([[1, 0, 0],
        [0, 2, 0],
        [0, 0, 3]], dtype=int64)
>>> Aexp = expm(A)
>>> Aexp
<3x3 sparse matrix of type '<class 'numpy.float64''>'
with 3 stored elements in Compressed Sparse Column format>
>>> Aexp.todense()
matrix([[ 2.71828183,  0.,  0.],
        [ 0.,  7.3890561,  0.],
        [ 0.,  0., 20.08553692]])
```

`scipy.sparse.linalg.expm_multiply(A, B, start=None, stop=None, num=None, endpoint=None)`

Compute the action of the matrix exponential of A on B.

**Parameters** **A** : transposable linear operator  
 The operator whose exponential is of interest.  
**B** : ndarray  
 The matrix or vector to be multiplied by the matrix exponential of A.  
**start** : scalar, optional  
 The starting time point of the sequence.  
**stop** : scalar, optional  
 The end time point of the sequence, unless *endpoint* is set to False. In that case, the sequence consists of all but the last of *num* + 1 evenly spaced time points, so that *stop* is excluded. Note that the step size changes when *endpoint* is False.  
**num** : int, optional  
 Number of time points to use.  
**endpoint** : bool, optional  
 If True, *stop* is the last time point. Otherwise, it is not included.  
**Returns** **expm\_A\_B** : ndarray  
 The result of the action  $e^{t_k A} B$ .

### Notes

The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of `numpy.linspace`.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, `expm_A_B[0]` will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

### References

[R374], [R375]

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm, expm_multiply
>>> A = csc_matrix([[1, 0], [0, 1]])
>>> A.todense()
matrix([[1, 0],
        [0, 1]], dtype=int64)
>>> B = np.array([np.exp(-1.), np.exp(-2.)])
>>> B
array([ 0.36787944,  0.13533528])
>>> expm_multiply(A, B, start=1, stop=2, num=3, endpoint=True)
array([[ 1.          ,  0.36787944],
       [ 1.64872127,  0.60653066],
       [ 2.71828183,  1.          ]])
>>> expm(A).dot(B) # Verify 1st timestep
array([ 1.          ,  0.36787944])
>>> expm(1.5*A).dot(B) # Verify 2nd timestep
array([ 1.64872127,  0.60653066])
>>> expm(2*A).dot(B) # Verify 3rd timestep
array([ 2.71828183,  1.          ])
```

## 5.22.3 Matrix norms

<code>norm(x[, ord, axis])</code>	Norm of a sparse matrix
<code>onenormest(A[, t, itmax, compute_v, compute_w])</code>	Compute a lower bound of the 1-norm of a sparse matrix.

`scipy.sparse.linalg.norm(x, ord=None, axis=None)`

Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the `ord` parameter.

**Parameters**

- x** : a sparse matrix  
Input sparse matrix.
- ord** : {non-zero int, inf, -inf, 'fro'}, optional  
Order of the norm (see table under `Notes`). `inf` means numpy's `inf` object.
- axis** : {int, 2-tuple of ints, None}, optional  
If `axis` is an integer, it specifies the axis of `x` along which to compute the vector norms. If `axis` is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If `axis` is `None` then

either a vector norm (when  $x$  is 1-D) or a matrix norm (when  $x$  is 2-D) is returned.

**Returns**  $n$  : float or ndarray

**Notes**

Some of the ord are not implemented because some associated functions like, `_multi_svd_norm`, are not yet available for sparse matrix.

This docstring is modified based on `numpy.linalg.norm`. <https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py>

The following norms can be calculated:

ord	norm for sparse matrices
None	Frobenius norm
'fro'	Frobenius norm
inf	<code>max(sum(abs(x), axis=1))</code>
-inf	<code>min(sum(abs(x), axis=1))</code>
0	<code>abs(x).sum(axis=axis)</code>
1	<code>max(sum(abs(x), axis=0))</code>
-1	<code>min(sum(abs(x), axis=0))</code>
2	Not implemented
-2	Not implemented
other	Not implemented

The Frobenius norm is given by [R389]:

$$\|A\|_F = [\sum_{i,j} abs(a_{i,j})^2]^{1/2}$$

**References**

[R389]

**Examples**

```
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1, 0, 1, 2, 3, 4])
>>> b = a.reshape((3, 3))
>>> b
array([[ -4,  -3,  -2],
       [ -1,   0,   1],
       [  2,   3,   4]])
```

```
>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
```

```
>>> norm(b, -1)
6
```

`scipy.sparse.linalg.onenormest` (*A*, *t*=2, *itmax*=5, *compute\_v*=False, *compute\_w*=False)  
 Compute a lower bound of the 1-norm of a sparse matrix.

**Parameters**

- A** : ndarray or other linear operator  
 A linear operator that can be transposed and that can produce matrix products.
- t** : int, optional  
 A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.
- itmax** : int, optional  
 Use at most this many iterations.
- compute\_v** : bool, optional  
 Request a norm-maximizing linear operator input vector if True.
- compute\_w** : bool, optional  
 Request a norm-maximizing linear operator output vector if True.

**Returns**

- est** : float  
 An underestimate of the 1-norm of the sparse matrix.
- v** : ndarray, optional  
 The vector such that  $\|Av\|_1 == est * \|v\|_1$ . It can be thought of as an input to the linear operator that gives an output with particularly large norm.
- w** : ndarray, optional  
 The vector  $Av$  which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

### Notes

This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about  $4t$  matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

### References

[R390], [R391]

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import onenormest
>>> A = csc_matrix([[1., 0., 0.], [5., 8., 2.], [0., -1., 0.]], dtype=float)
>>> A.todense()
matrix([[ 1.,  0.,  0.],
        [ 5.,  8.,  2.],
        [ 0., -1.,  0.]])
>>> onenormest(A)
9.0
>>> np.linalg.norm(A.todense(), ord=1)
9.0
```

## 5.22.4 Solving linear problems

Direct methods for linear equation systems:

<code>spsolve(A, b[, permc_spec, use_umfpack])</code>	Solve the sparse linear system $Ax=b$ , where $b$ may be a vector or a matrix.
<code>spsolve_triangular(A, b[, lower, ...])</code>	Solve the equation $Ax = b$ for $x$ , assuming $A$ is a triangular matrix.
<code>factorized(A)</code>	Return a function for solving a sparse linear system, with $A$ pre-factorized.
<code>MatrixRankWarning</code>	
<code>use_solver(**kwargs)</code>	Select default sparse direct solver to be used.

`scipy.sparse.linalg.spsolve(A, b, permc_spec=None, use_umfpack=True)`

Solve the sparse linear system  $Ax=b$ , where  $b$  may be a vector or a matrix.

**Parameters**

- A** : ndarray or sparse matrix  
The square matrix  $A$  will be converted into CSC or CSR form
- b** : ndarray or sparse matrix  
The matrix or vector representing the right hand side of the equation. If a vector,  $b.shape$  must be  $(n,)$  or  $(n, 1)$ .
- permc\_spec** : str, optional  
How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')
  - NATURAL: natural ordering.
  - MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
  - MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T + A$ .
  - COLAMD: approximate minimum degree column ordering
- use\_umfpack** : bool, optional  
if True (default) then use umfpack for the solution. This is only referenced if  $b$  is a vector and `scikit-umfpack` is installed.

**Returns**

- x** : ndarray or sparse matrix  
the solution of the sparse linear equation. If  $b$  is a vector, then  $x$  is a vector of size  $A.shape[1]$  If  $b$  is a matrix, then  $x$  is a matrix of size  $(A.shape[1], b.shape[1])$

### Notes

For solving the matrix expression  $AX = B$ , this solver assumes the resulting matrix  $X$  is sparse, as is often the case for very sparse inputs. If the resulting  $X$  is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting  $A$  to a dense matrix and using `scipy.linalg.solve` or its variants.

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spsolve
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> B = csc_matrix([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve(A, B)
>>> np.allclose(A.dot(x).todense(), B.todense())
True
```

`scipy.sparse.linalg.spsolve_triangular(A, b, lower=True, overwrite_A=False, overwrite_b=False)`

Solve the equation  $Ax = b$  for  $x$ , assuming  $A$  is a triangular matrix.

**Parameters**

- A** : (M, M) sparse matrix  
A sparse square triangular matrix. Should be in CSR format.
- b** : (M,) or (M, N) array\_like  
Right-hand side matrix in  $A x = b$
- lower** : bool, optional  
Whether *A* is a lower or upper triangular matrix. Default is lower triangular matrix.
- overwrite\_A** : bool, optional  
Allow changing *A*. The indices of *A* are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.
- overwrite\_b** : bool, optional  
Allow overwriting data in *b*. Enabling gives a performance gain. Default is False. If *overwrite\_b* is True, it should be ensured that *b* has an appropriate dtype to be able to store the result.

**Returns** **x** : (M,) or (M, N) ndarray  
Solution to the system  $A x = b$ . Shape of return matches shape of *b*.

**Raises**

- LinAlgError**  
If *A* is singular or not triangular.
- ValueError**  
If shape of *A* or shape of *b* do not match the requirements.

**Notes**

New in version 0.19.0.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.linalg import spsolve_triangular
>>> A = csr_matrix([[3, 0, 0], [1, -1, 0], [2, 0, 1]], dtype=float)
>>> B = np.array([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve_triangular(A, B)
>>> np.allclose(A.dot(x), B)
True
```

`scipy.sparse.linalg.factorized(A)`

Return a function for solving a sparse linear system, with *A* pre-factorized.

**Parameters** **A** : (N, N) array\_like  
Input.

**Returns** **solve** : callable  
To solve the linear system of equations given in *A*, the *solve* callable should be passed an ndarray of shape (N,).

**Examples**

```
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[ 3. ,  2. , -1. ],
...              [ 2. , -2. ,  4. ],
...              [-1. ,  0.5, -1. ]])
>>> solve = factorized(A) # Makes LU decomposition.
>>> rhs1 = np.array([1, -2, 0])
>>> solve(rhs1) # Uses the LU factors.
array([ 1., -2., -2.])
```

exception `scipy.sparse.linalg.MatrixRankWarning`

`scipy.sparse.linalg.use_solver(**kwargs)`

Select default sparse direct solver to be used.

**Parameters**

- useUmfpack** : bool, optional  
Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True
- assumeSortedIndices** : bool, optional  
Allow UMFPACK to skip the step of sorting indices for a CSR/CSC matrix. Has effect only if useUmfpack is True and scikits.umfpack is installed. Default: False

**Notes**

The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing `useUmfpack = False`, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass `assumeSortedIndices=True` to gain some speed.

Iterative methods for linear equation systems:

<code>bicg(A, b[, x0, tol, maxiter, M, callback])</code>	Use BIConjugate Gradient iteration to solve $Ax = b$ .
<code>bicgstab(A, b[, x0, tol, maxiter, M, callback])</code>	Use BIConjugate Gradient STABILized iteration to solve $Ax = b$ .
<code>cg(A, b[, x0, tol, maxiter, M, callback])</code>	Use Conjugate Gradient iteration to solve $Ax = b$ .
<code>cgs(A, b[, x0, tol, maxiter, M, callback])</code>	Use Conjugate Gradient Squared iteration to solve $Ax = b$ .
<code>gmres(A, b[, x0, tol, restart, maxiter, M, ...])</code>	Use Generalized Minimal RESidual iteration to solve $Ax = b$ .
<code>lgmres(A, b[, x0, tol, maxiter, M, ...])</code>	Solve a matrix equation using the LGMRES algorithm.
<code>minres(A, b[, x0, shift, tol, maxiter, M, ...])</code>	Use MINimum RESidual iteration to solve $Ax=b$
<code>qmr(A, b[, x0, tol, maxiter, M1, M2, callback])</code>	Use Quasi-Minimal Residual iteration to solve $Ax = b$ .
<code>gcrotmk(A, b[, x0, tol, maxiter, M, ...])</code>	Solve a matrix equation using flexible GCROT(m,k) algorithm.

`scipy.sparse.linalg.bicg(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)`

Use BIConjugate Gradient iteration to solve  $Ax = b$ .

**Parameters**

- A** : {sparse matrix, dense matrix, LinearOperator}  
The real or complex N-by-N matrix of the linear system. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .
- b** : {array, matrix}  
Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- x** : {array, matrix}  
The converged solution.
- info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

- x0** : {array, matrix}  
Starting guess for the solution.
- tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below `tol`.
- maxiter** : integer

Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

`scipy.sparse.linalg.bicgstab(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)`

Use BIConjugate Gradient STABILized iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real or complex N-by-N matrix of the linear system.

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}

Starting guess for the solution.

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below `tol`.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

`scipy.sparse.linalg.cg(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)`

Use Conjugate Gradient iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real or complex N-by-N matrix of the linear system. A must represent a hermitian, positive definite matrix.

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not

achieved, number of iterations <0 : illegal input or break-down

**Other Parameters**

- x0** : {array, matrix}  
Starting guess for the solution.
- tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- maxiter** : integer  
Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}  
Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** : function  
User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

`scipy.sparse.linalg.cgs` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*)

Use Conjugate Gradient Squared iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}  
The real-valued N-by-N matrix of the linear system.

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or break-down

**Other Parameters**

- x0** : {array, matrix}  
Starting guess for the solution.
- tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- maxiter** : integer  
Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}  
Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** : function  
User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

`scipy.sparse.linalg.gmres` (*A*, *b*, *x0=None*, *tol=1e-05*, *restart=None*, *maxiter=None*, *M=None*, *callback=None*, *restrt=None*)

Use Generalized Minimal RESidual iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}  
The real or complex N-by-N matrix of the linear system.

**Returns**

**b** : {array, matrix}  
Right hand side of the linear system. Has shape (N,) or (N,1).

**x** : {array, matrix}  
The converged solution.

**info** : int  
*Provides convergence information:*

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}  
Starting guess for the solution (a vector of zeros by default).

**tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**restart** : int, optional  
Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.

**maxiter** : int, optional  
Maximum number of iterations (restart cycles). Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}  
Inverse of the preconditioner of A. M should approximate the inverse of A and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.

**callback** : function  
User-supplied function to call after each iteration. It is called as `callback(rk)`, where *rk* is the current residual vector.

**restrt** : int, optional  
DEPRECATED - use *restart* instead.

**See also:***LinearOperator***Notes**

A preconditioner, *P*, is chosen such that *P* is close to *A* but easy to solve for. The preconditioner parameter required by this routine is  $M = P^{-1}$ . The inverse should preferably not be calculated explicitly. Rather, use the following template to produce *M*:

```
# Construct a linear operator that computes  $P^{-1} * x$ .
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import gmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = gmres(A, b)
```

```
>>> print(exitCode)           # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

`scipy.sparse.linalg.lgmres` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=1000*, *M=None*, *callback=None*, *inner\_m=30*, *outer\_k=3*, *outer\_v=None*, *store\_outer\_Av=True*, *prepend\_outer\_v=False*)

Solve a matrix equation using the LGMRES algorithm.

The LGMRES algorithm [R379] [R380] is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

**Parameters**

- A** : {sparse matrix, dense matrix, LinearOperator}
 

The real or complex N-by-N matrix of the linear system.
- b** : {array, matrix}
 

Right hand side of the linear system. Has shape (N,) or (N,1).
- x0** : {array, matrix}
 

Starting guess for the solution.
- tol** : float, optional
 

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- maxiter** : int, optional
 

Maximum number of iterations. Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}, optional
 

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** : function, optional
 

User-supplied function to call after each iteration. It is called as `callback(xk)`, where *xk* is the current solution vector.
- inner\_m** : int, optional
 

Number of inner GMRES iterations per each outer iteration.
- outer\_k** : int, optional
 

Number of vectors to carry between inner GMRES iterations. According to [R379], good values are in the range of 1...3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.
- outer\_v** : list of tuples, optional
 

List containing tuples (*v*, *Av*) of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element *Av* can be *None* if the matrix-vector product should be re-evaluated. This parameter is modified in-place by *lgmres*, and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems.
- store\_outer\_Av** : bool, optional
 

Whether LGMRES should store also  $A*v$  in addition to vectors *v* in the *outer\_v* list. Default is True.
- prepend\_outer\_v** : bool, optional
 

Whether to put *outer\_v* augmentation vectors before Krylov iterates. In standard LGMRES, `prepend_outer_v=False`.

**Returns**

- x** : array or matrix
 

The converged solution.

**info** : int

Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

**Notes**

The LGMRES algorithm [R379] [R380] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the *outer\_v* argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lgmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = lgmres(A, b)
>>> print(exitCode)           # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

`scipy.sparse.linalg.minres` (*A*, *b*, *x0=None*, *shift=0.0*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *show=False*, *check=False*)

Use MINimum RESidual iteration to solve  $Ax=b$ 

MINRES minimizes  $\text{norm}(A*x - b)$  for a real symmetric matrix *A*. Unlike the Conjugate Gradient method, *A* can be indefinite or singular.

If *shift* != 0 then the method solves  $(A - \text{shift}*I)x = b$ **Parameters** *A* : {sparse matrix, dense matrix, LinearOperator}

The real symmetric N-by-N matrix of the linear system

*b* : {array, matrix}

Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns** *x* : {array, matrix}

The converged solution.

**info** : integer**Provides convergence information:**

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

**Other Parameters***x0* : {array, matrix}

Starting guess for the solution.

*tol* : floatTolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

*Notes*

THIS FUNCTION IS EXPERIMENTAL AND SUBJECT TO CHANGE!

`scipy.sparse.linalg.qmr(A, b, x0=None, tol=1e-05, maxiter=None, M1=None, M2=None, callback=None)`

Use Quasi-Minimal Residual iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real-valued N-by-N matrix of the linear system. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

**b** : {array, matrix}

Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns** **x** : {array, matrix}

The converged solution.

**info** : integer

*Provides convergence information:*

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

*Other Parameters*

**x0** : {array, matrix}

Starting guess for the solution.

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M1** : {sparse matrix, dense matrix, LinearOperator}

Left preconditioner for A.

**M2** : {sparse matrix, dense matrix, LinearOperator}

Right preconditioner for A. Used together with the left preconditioner M1. The matrix  $M1 * A * M2$  should have better conditioned than A alone.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

*LinearOperator*

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import qmr
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = qmr(A, b)
>>> print(exitCode)           # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

`scipy.sparse.linalg.gcrotmk` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=1000*, *M=None*, *callback=None*, *m=20*, *k=None*, *CU=None*, *discard\_C=False*, *truncate='oldest'*)  
Solve a matrix equation using flexible GCROT(m,k) algorithm.

**Parameters**

- A** : {sparse matrix, dense matrix, LinearOperator}  
The real or complex N-by-N matrix of the linear system.
- b** : {array, matrix}  
Right hand side of the linear system. Has shape (N,) or (N,1).
- x0** : {array, matrix}  
Starting guess for the solution.
- tol** : float, optional  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- maxiter** : int, optional  
Maximum number of iterations. Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}, optional  
Preconditioner for A. The preconditioner should approximate the inverse of A. `gcrotmk` is a ‘flexible’ algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** : function, optional  
User-supplied function to call after each iteration. It is called as `callback(xk)`, where *xk* is the current solution vector.
- m** : int, optional  
Number of inner FGMRES iterations per each outer iteration. Default: 20
- k** : int, optional  
Number of vectors to carry between inner FGMRES iterations. According to [R377], good values are around *m*. Default: *m*
- CU** : list of tuples, optional  
List of tuples (*c*, *u*) which contain the columns of the matrices C and U in the GCROT(m,k) algorithm. For details, see [R377]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The *c* elements in the tuples can be `None`, in which case the vectors are recomputed via  $c = A u$  on start and orthogonalized as described in [R378].
- discard\_C** : bool, optional  
Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.

**truncate** : { 'oldest', 'smallest' }, optional  
 Truncation scheme to use. Drop: oldest vectors, or vectors with smallest singular values using the scheme discussed in [1,2]. See [R377] for detailed comparison. Default: 'oldest'

**Returns** **x** : array or matrix  
 The solution found.

**info** : int  
 Provides convergence information:  
 •0 : successful exit  
 •>0 : convergence to tolerance not achieved, number of iterations

**References**

[R376], [R377], [R378]

Iterative methods for least-squares problems:

<code>lsqr(A, b[, damp, atol, btol, conlim, ...])</code>	Find the least-squares solution to a large, sparse, linear system of equations.
<code>lsmr(A, b[, damp, atol, btol, conlim, ...])</code>	Iterative solver for least-squares problems.

`scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-08, btol=1e-08, conlim=100000000.0, iter_lim=None, show=False, calc_var=False, x0=None)`

Find the least-squares solution to a large, sparse, linear system of equations.

The function solves  $Ax = b$  or  $\min ||b - Ax||^2$  or  $\min ||Ax - b||^2 + d^2 ||x||^2$ .

The matrix A may be square or rectangular (over-determined or under-determined), and may have any rank.

```

1. Unsymmetric equations -- solve A*x = b
2. Linear least squares -- solve A*x = b
                           in the least-squares sense
3. Damped least squares -- solve ( A ) * x = ( b )
                           ( damp*I ) ( 0 )
                           in the least-squares sense
    
```

**Parameters** **A** : {sparse matrix, ndarray, LinearOperator}  
 Representation of an m-by-n matrix. It is required that the linear operator can produce Ax and A^T x.

**b** : array\_like, shape (m,)  
 Right-hand side vector b.

**damp** : float  
 Damping coefficient.

**atol, btol** : float, optional  
 Stopping tolerances. If both are 1.0e-9 (say), the final residual norm should be accurate to about 9 digits. (The final x will usually have fewer correct digits, depending on cond(A) and the size of damp.)

**conlim** : float, optional  
 Another stopping tolerance. lsqr terminates if an estimate of cond(A) exceeds conlim. For compatible systems Ax = b, conlim could be as large as 1.0e+12 (say). For least-squares problems, conlim should be less than 1.0e+8. Maximum precision can be obtained by setting atol = btol = conlim = zero, but the number of iterations may then be excessive.

**iter\_lim** : int, optional

Explicit limitation on number of iterations (for safety).

**show** : bool, optional  
Display an iteration log.

**calc\_var** : bool, optional  
Whether to estimate diagonals of  $(A'A + \text{damp}^2 * I)^{-1}$ .

**x0** : array\_like, shape (n,), optional  
Initial guess of x, if None zeros are used.

**Returns** **x** : ndarray of float  
New in version 1.0.0.  
The final solution.

**istop** : int  
Gives the reason for termination. 1 means x is an approximate solution to  $Ax = b$ . 2 means x approximately solves the least-squares problem.

**itn** : int  
Iteration number upon termination.

**r1norm** : float  
 $\text{norm}(r)$ , where  $r = b - Ax$ .

**r2norm** : float  
 $\sqrt{\text{norm}(r)^2 + \text{damp}^2 * \text{norm}(x)^2}$ . Equal to *r1norm* if  $\text{damp} == 0$ .

**anorm** : float  
Estimate of Frobenius norm of  $A_{\text{bar}} = \begin{bmatrix} A \\ \text{damp} * I \end{bmatrix}$ .

**acond** : float  
Estimate of  $\text{cond}(A_{\text{bar}})$ .

**arnorm** : float  
Estimate of  $\text{norm}(A' * r - \text{damp}^2 * x)$ .

**xnorm** : float  
 $\text{norm}(x)$

**var** : ndarray of float  
If **calc\_var** is True, estimates all diagonals of  $(A'A)^{-1}$  (if  $\text{damp} == 0$ ) or more generally  $(A'A + \text{damp}^2 * I)^{-1}$ . This is well defined if A has full column rank or  $\text{damp} > 0$ . (Not sure what var means if  $\text{rank}(A) < n$  and  $\text{damp} = 0$ .)

### Notes

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of A should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of A is very small or large compared to the other rows of A, the corresponding row of  $(A \ b)$  should be scaled up or down.

In problems 1 and 2, the solution x is easily recovered following column-scaling. Unless better information is known, the nonzero columns of A should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if damp is nonzero. However, the value of damp should be assigned only after attention has been paid to the scaling of A.

The parameter damp is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter acond, which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate x0 is known and if  $\text{damp} == 0$ , one could proceed as follows:

1. Compute a residual vector  $r0 = b - A * x0$ .
2. Use LSQR to solve the system  $A * dx = r0$ .
3. Add the correction dx to obtain a final solution  $x = x0 + dx$ .

This requires that  $x_0$  be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes  $k_1$  iterations to solve  $A*x = b$  and  $k_2$  iterations to solve  $A*dx = r_0$ . If  $x_0$  is “good”,  $\text{norm}(r_0)$  will be smaller than  $\text{norm}(b)$ . If the same stopping tolerances  $\text{atol}$  and  $\text{btol}$  are used for each system,  $k_1$  and  $k_2$  will be similar, but the final solution  $x_0 + dx$  should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value  $\text{btol}$  is suitable for  $A*x = b$ , the larger value  $\text{btol}*\text{norm}(b)/\text{norm}(r_0)$  should be suitable for  $A*dx = r_0$ .

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system  $M*x = b$  efficiently, where  $M$  approximates  $A$  in some helpful way (e.g.  $M - A$  has low rank or its elements are small relative to those of  $A$ ), LSQR may converge more rapidly on the system  $A*M(\text{inverse})*z = b$ , after which  $x$  can be recovered by solving  $M*x = z$ .

If  $A$  is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (`cg`) and/or `SYMMLQ`. `SYMMLQ` is an implementation of symmetric `cg` that applies to any symmetric  $A$  and will converge more rapidly than LSQR. If  $A$  is positive definite, there are other implementations of symmetric `cg` that require slightly less work per iteration than `SYMMLQ` (but will take the same number of iterations).

### References

[R386], [R387], [R388]

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution  $[0, 0]$

```
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
The exact solution is x = 0
>>> istop
0
>>> x
array([ 0.,  0.]
```

The stopping code `istop=0` returned indicates that a vector of zeros was found as a solution. The returned solution  $x$  indeed contains  $[0, 0]$ . The next example has a non-trivial solution:

```
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, rlnorm = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> rlnorm
4.440892098500627e-16
```

As indicated by `istop=1`, `lsqr` found a solution obeying the tolerance limits. The given solution  $[1., -1.]$  obviously solves the equation. The remaining return values include information about the number of iterations (`itn=1`) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```

>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, rlnorm = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333,  0.00333333])
>>> rlnorm
0.005773502691896255

```

*istop* indicates that the system is inconsistent and thus *x* is rather an approximate solution to the corresponding least-squares problem. *rlnorm* contains the norm of the minimal residual that was found.

`scipy.sparse.linalg.lsmr(A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=100000000.0, maxiter=None, show=False, x0=None)`  
Iterative solver for least-squares problems.

*lsmr* solves the system of linear equations  $Ax = b$ . If the system is inconsistent, it solves the least-squares problem  $\min ||b - Ax||_2$ . *A* is a rectangular matrix of dimension *m*-by-*n*, where all cases are allowed:  $m = n$ ,  $m > n$ , or  $m < n$ . *B* is a vector of length *m*. The matrix *A* may be dense or sparse (usually sparse).

**Parameters** *A* : {matrix, sparse matrix, ndarray, LinearOperator}  
Matrix *A* in the linear system.

*b* : array\_like, shape (*m*,)  
Vector *b* in the linear system.

**damp** : float  
Damping factor for regularized least-squares. *lsmr* solves the regularized least-squares problem:

$$\min \begin{pmatrix} ||(b) - (A)x|| \\ ||(0) \quad (damp * I)||_2 \end{pmatrix}$$

where *damp* is a scalar. If *damp* is *None* or 0, the system is solved without regularization.

**atol, btol** : float, optional

Stopping tolerances. *lsmr* continues iterations until a certain backward error estimate is smaller than some quantity depending on *atol* and *btol*. Let  $r = b - Ax$  be the residual vector for the current approximate solution *x*. If  $Ax = b$  seems to be consistent, *lsmr* terminates when  $\text{norm}(r) \leq \text{atol} * \text{norm}(A) * \text{norm}(x) + \text{btol} * \text{norm}(b)$ . Otherwise, *lsmr* terminates when  $\text{norm}(A^T r) \leq \text{atol} * \text{norm}(A) * \text{norm}(r)$ . If both tolerances are 1.0e-6 (say), the final  $\text{norm}(r)$  should be accurate to about 6 digits. (The final *x* will usually have fewer correct digits, depending on  $\text{cond}(A)$  and the size of *LAMBDA*.) If *atol* or *btol* is *None*, a default value of 1.0e-6 will be used. Ideally, they should be estimates of the relative error in the entries of *A* and *B* respectively. For example, if the entries of *A* have 7 correct digits, set *atol* = 1e-7. This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

**conlim** : float, optional

*lsmr* terminates if an estimate of  $\text{cond}(A)$  exceeds *conlim*. For compatible systems  $Ax = b$ , *conlim* could be as large as 1.0e+12 (say). For least-squares problems, *conlim* should be less than 1.0e+8. If *conlim* is *None*, the default value is 1e+8. Maximum precision can be obtained by setting *atol* = *btol* = *conlim* = 0, but the number of iterations may then be excessive.

**maxiter** : int, optional

*lsqr* terminates if the number of iterations reaches *maxiter*. The default is  $\text{maxiter} = \min(m, n)$ . For ill-conditioned systems, a larger value of *maxiter* may be needed.

**show** : bool, optional

Print iterations logs if `show=True`.

**x0** : array\_like, shape (n,), optional

Initial guess of x, if None zeros are used.

New in version 1.0.0.

### Returns

**x** : ndarray of float

Least-square solution returned.

**istop** : int

istop gives the reason for stopping:

```

istop   = 0 means x=0 is a solution.  If x0 was given,
→then x=x0 is a
        solution.
        = 1 means x is an approximate solution to A*x
→= B,
        according to atol and btol.
        = 2 means x approximately solves the least-
→squares problem
        according to atol.
        = 3 means COND(A) seems to be greater than
→CONLIM.
        = 4 is the same as 1 with atol = btol = eps
→(machine
        precision)
        = 5 is the same as 2 with atol = eps.
        = 6 is the same as 3 with CONLIM = 1/eps.
        = 7 means ITN reached maxiter before the other
→stopping
        conditions were satisfied.
    
```

**itn** : int

Number of iterations used.

**normr** : float

$\text{norm}(b - Ax)$

**normar** : float

$\text{norm}(A^T (b - Ax))$

**norma** : float

$\text{norm}(A)$

**conda** : float

Condition number of A.

**normx** : float

$\text{norm}(x)$

### Notes

New in version 0.11.0.

### References

[R384], [R385]

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution  $[0, 0]$

```
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
0
>>> x
array([ 0.,  0.]
```

The stopping code `istop=0` returned indicates that a vector of zeros was found as a solution. The returned solution `x` indeed contains  $[0, 0]$ . The next example has a non-trivial solution:

```
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> normr
4.440892098500627e-16
```

As indicated by `istop=1`, `lsqr` found a solution obeying the tolerance limits. The given solution  $[1, -1]$  obviously solves the equation. The remaining return values include information about the number of iterations (`itn=1`) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333,  0.00333333])
>>> normr
0.005773502691896255
```

`istop` indicates that the system is inconsistent and thus `x` is rather an approximate solution to the corresponding least-squares problem. `normr` contains the minimal distance that was found.

**5.22.5 Matrix factorizations**

Eigenvalue problems:

`eigs(A[, k, M, sigma, which, v0, ncv, ...])`

Find `k` eigenvalues and eigenvectors of the square matrix `A`.

Continued on next page

Table 5.212 – continued from previous page

<code>eigsh(A[, k, M, sigma, which, v0, ncv, ...])</code>	Find $k$ eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix $A$ .
<code>lobpcg(A, X[, B, M, Y, tol, maxiter, ...])</code>	Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

`scipy.sparse.linalg.eigs` ( $A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvectors=True, Minv=None, OPinv=None, OPpart=None$ )

Find  $k$  eigenvalues and eigenvectors of the square matrix  $A$ .

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$ .

If  $M$  is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$

**Parameters**  $A$  : ndarray, sparse matrix or LinearOperator

An array, sparse matrix, or LinearOperator representing the operation  $A * x$ , where  $A$  is a real or complex square matrix.

$k$  : int, optional

The number of eigenvalues and eigenvectors desired.  $k$  must be smaller than  $N-1$ . It is not possible to compute all eigenvectors of a matrix.

$M$  : ndarray, sparse matrix or LinearOperator, optional

An array, sparse matrix, or LinearOperator representing the operation  $M*x$  for the generalized eigenvalue problem

$$A * x = w * M * x.$$

$M$  must represent a real, symmetric matrix if  $A$  is real, and must represent a complex, hermitian matrix if  $A$  is complex. For best results, the data type of  $M$  should be the same as that of  $A$ . Additionally:

If  $sigma$  is None,  $M$  is positive definite

If  $sigma$  is specified,  $M$  is positive semi-definite

If  $sigma$  is None, `eigs` requires an operator to compute the solution of the linear equation  $M * x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix  $M$ , or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator `Minv`, which gives  $x = Minv * b = M^{-1} * b$ .

$sigma$  : real or complex, optional

Find eigenvalues near  $sigma$  using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - sigma * M] * x = b$ , where  $M$  is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices  $A$  &  $M$ , or via an iterative solver if either  $A$  or  $M$  is a general linear operator. Alternatively, the user can supply the matrix or operator `OPinv`, which gives  $x = OPinv * b = [A - sigma * M]^{-1} * b$ . For a real matrix  $A$ , shift-invert can either be done in imaginary mode or real mode, specified by the parameter `OPpart` ('r' or 'i'). Note that when  $sigma$  is specified, the keyword 'which' (below) refers to the shifted eigenvalues  $w'[i]$  where:

**If  $A$  is real and `OPpart == 'r'` (default),**

$$w'[i] = 1/2 * [1/(w[i]-sigma) + 1/(w[i]-conj(sigma))].$$

**If  $A$  is real and `OPpart == 'i'`,**

$$w'[i] = 1/2i * [1/(w[i]-sigma) - 1/(w[i]-conj(sigma))].$$

If  $A$  is complex,  $w'[i] = 1/(w[i]-\sigma)$ .

**v0** : ndarray, optional

Starting vector for iteration. Default: random

**ncv** : int, optional

The number of Lanczos vectors generated  $ncv$  must be greater than  $k$ ; it is recommended that  $ncv > 2*k$ . Default:  $\min(n, \max(2*k + 1, 20))$

**which** : str, ['LM' | 'SM' | 'LR' | 'SR' | 'LI' | 'SI'], optional

Which  $k$  eigenvectors and eigenvalues to find:

'LM' : largest magnitude

'SM' : smallest magnitude

'LR' : largest real part

'SR' : smallest real part

'LI' : largest imaginary part

'SI' : smallest imaginary part

When  $\sigma \neq \text{None}$ , 'which' refers to the shifted eigenvalues  $w'[i]$  (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** : int, optional

Maximum number of Arnoldi update iterations allowed Default:  $n*10$

**tol** : float, optional

Relative accuracy for eigenvalues (stopping criterion) The default value of 0 implies machine precision.

**return\_eigenvectors** : bool, optional

Return eigenvectors (True) in addition to eigenvalues

**Minv** : ndarray, sparse matrix or LinearOperator, optional

See notes in  $M$ , above.

**OPinv** : ndarray, sparse matrix or LinearOperator, optional

See notes in  $\sigma$ , above.

**OPpart** : {'r' or 'i'}, optional

See notes in  $\sigma$ , above

#### Returns

**w** : ndarray

Array of  $k$  eigenvalues.

**v** : ndarray

An array of  $k$  eigenvectors.  $v[:, i]$  is the eigenvector corresponding to the eigenvalue  $w[i]$ .

#### Raises

**ArpackNoConvergence**

When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

#### See also:

**eigsh** eigenvalues and eigenvectors for symmetric matrix  $A$   
**svds** singular value decomposition for a matrix  $A$

#### Notes

This function is a wrapper to the ARPACK [R369] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [R370].

#### References

[R369], [R370]

### Examples

Find 6 eigenvectors of the identity matrix:

```
>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigs(id, k=6)
>>> vals
array([ 1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j])
>>> vecs.shape
(13, 6)
```

`scipy.sparse.linalg.eigsh`(*A*, *k*=6, *M*=None, *sigma*=None, *which*='LM', *v0*=None, *ncv*=None, *maxiter*=None, *tol*=0, *return\_eigenvectors*=True, *Minv*=None, *OPinv*=None, *mode*='normal')

Find *k* eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix *A*.

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for *w*[*i*] eigenvalues with corresponding eigenvectors *x*[*i*].

If *M* is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for *w*[*i*] eigenvalues with corresponding eigenvectors *x*[*i*]

**Parameters** *A* : An *N* x *N* matrix, array, sparse matrix, or LinearOperator representing the operation  $A * x$ , where *A* is a real symmetric matrix For buckling mode (see below) *A* must additionally be positive-definite

*k* : int, optional

The number of eigenvalues and eigenvectors desired. *k* must be smaller than *N*. It is not possible to compute all eigenvectors of a matrix.

**Returns** *w* : array

Array of *k* eigenvalues

*v* : array

An array representing the *k* eigenvectors. The column  $v[:, i]$  is the eigenvector corresponding to the eigenvalue *w*[*i*].

#### Other Parameters

*M* : An *N* x *N* matrix, array, sparse matrix, or linear operator representing the operation  $M * x$  for the generalized eigenvalue problem  $A * x = w * M * x$ .

*M* must represent a real, symmetric matrix if *A* is real, and must represent a complex, hermitian matrix if *A* is complex. For best results, the data type of *M* should be the same as that of *A*. Additionally:

If *sigma* is None, *M* is symmetric positive definite

If *sigma* is specified, *M* is symmetric positive semi-definite

In buckling mode, *M* is symmetric indefinite.

If *sigma* is None, `eigsh` requires an operator to compute the solution of the linear equation  $M * x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix *M*, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator *Minv*, which gives  $x = Minv * b = M^{-1} * b$ .

*sigma* : real

Find eigenvalues near *sigma* using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - sigma * M] x = b$ , where *M* is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices *A* & *M*, or via an iterative solver if either *A* or *M* is a general linear operator. Alternatively, the user can supply the matrix or operator *OPinv*, which gives  $x = OPinv * b = [A - sigma * M]^{-1} * b$ . Note that when *sigma* is specified, the keyword 'which' refers to the shifted eigenvalues *w*' [*i*] where:

```

if mode == 'normal', w'[i] = 1 / (w[i] -
sigma).
if mode == 'cayley', w'[i] = (w[i] + sigma) /
(w[i] - sigma).
if mode == 'buckling', w'[i] = w[i] / (w[i] -
sigma).

```

(see further discussion in 'mode' below)

**v0** : ndarray, optional

Starting vector for iteration. Default: random

**ncv** : int, optional

The number of Lanczos vectors generated ncv must be greater than k and smaller than n; it is recommended that  $ncv > 2*k$ . Default:  $\min(n, \max(2*k + 1, 20))$

**which** : str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']

If A is a complex hermitian matrix, 'BE' is invalid. Which k eigenvectors and eigenvalues to find:

```

'LM' : Largest (in magnitude) eigenvalues
'SM' : Smallest (in magnitude) eigenvalues
'LA' : Largest (algebraic) eigenvalues
'SA' : Smallest (algebraic) eigenvalues
'BE' : Half (k/2) from each end of the spectrum

```

When k is odd, return one more (k/2+1) from the high end. When sigma != None, 'which' refers to the shifted eigenvalues w'[i] (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** : int, optional

Maximum number of Arnoldi update iterations allowed Default: n\*10

**tol** : float

Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

**Minv** : N x N matrix, array, sparse matrix, or LinearOperator

See notes in M, above

**OPinv** : N x N matrix, array, sparse matrix, or LinearOperator

See notes in sigma, above.

**return\_eigenvectors** : bool

Return eigenvectors (True) in addition to eigenvalues

**mode** : string ['normal' | 'buckling' | 'cayley']

Specify strategy to use for shift-invert mode. This argument applies only for real-valued A and sigma != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem  $OP * x'[i] = w'[i] * B * x'[i]$  and transforms the resulting Ritz vectors x'[i] and Ritz values w'[i] into the desired eigenvectors and eigenvalues of the problem  $A * x[i] = w[i] * M * x[i]$ . The modes are as follows:

```

'normal' :   OP = [A - sigma * M]^-1 * M, B = M, w'[i]
             = 1 / (w[i] - sigma)
'buckling' : OP = [A - sigma * M]^-1 * A, B = A, w'[i] =
             w[i] / (w[i] - sigma)
'cayley' :   OP = [A - sigma * M]^-1 * [A + sigma * M],
             B = M, w'[i] = (w[i] + sigma) / (w[i] - sigma)

```

The choice of mode will affect which eigenvalues are selected by the keyword 'which', and can also impact the stability of convergence (see [2] for a discussion)

*Raises*

**ArpackNoConvergence**

When the requested convergence is not obtained.  
 The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

**See also:**

**eigs** eigenvalues and eigenvectors for a general (nonsymmetric) matrix A  
**svds** singular value decomposition for a matrix A

**Notes**

This function is a wrapper to the ARPACK [R371] SSEUPD and DSEUPD functions which use the Implicitly Restarted Lanczos Method to find the eigenvalues and eigenvectors [R372].

**References**

[R371], [R372]

**Examples**

```
>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigsh(id, k=6)
>>> vals
array([ 1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j])
>>> vecs.shape
(13, 6)
```

`scipy.sparse.linalg.lobpcg(A, X, B=None, M=None, Y=None, tol=None, maxiter=20, largest=True, verbosityLevel=0, retLambdaHistory=False, retResidualNormsHistory=False)`

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

- Parameters**
  - A** : {sparse matrix, dense matrix, LinearOperator}
 

The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.
  - X** : array\_like
 

Initial approximation to the k eigenvectors. If A has shape=(n,n) then X should have shape shape=(n,k).
  - B** : {dense matrix, sparse matrix, LinearOperator}, optional
 

the right hand side operator in a generalized eigenproblem. by default, B = Identity often called the “mass matrix”
  - M** : {dense matrix, sparse matrix, LinearOperator}, optional
 

preconditioner to A; by default M = Identity M should approximate the inverse of A
  - Y** : array\_like, optional
 

n-by-sizeY matrix of constraints, sizeY < n The iterations will be performed in the B-orthogonal complement of the column-space of Y. Y must be full rank.
- Returns**
  - w** : array
 

Array of k eigenvalues
  - v** : array
 

An array of k eigenvectors. V has the same shape as X.
- Other Parameters**
  - tol** : scalar, optional
 

Solver tolerance (stopping criterion) by default: `tol=n*sqrt(eps)`

**maxiter** : integer, optional  
 maximum number of iterations by default: `maxiter=min(n,20)`

**largest** : bool, optional  
 when True, solve for the largest eigenvalues, otherwise the smallest

**verbosityLevel** : integer, optional  
 controls solver output. default: `verbosityLevel = 0`.

**retLambdaHistory** : boolean, optional  
 whether to return eigenvalue history

**retResidualNormsHistory** : boolean, optional  
 whether to return history of residual norms

### Notes

If both `retLambdaHistory` and `retResidualNormsHistory` are True, the return tuple has the following format (lambda, V, lambda history, residual norms history).

In the following `n` denotes the matrix size and `m` the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size  $3 \times m$  on every iteration by calling the “standard” dense eigensolver, so if `m` is not small enough compared to `n`, it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. `numpy` or `scipy` function in this case. If one calls the LOBPCG algorithm for  $5 \times m > n$ , it will most likely break internally, so the code tries to call the standard function instead.

It is not that `n` should be large for the LOBPCG to work, but rather the ratio `n/m` should be large. If you call the LOBPCG code with `m=1` and `n=10`, it should work, though `n` is small. The method is intended for extremely large `n/m`, see e.g., reference [28] in <http://arxiv.org/abs/0705.2626>

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary `m` to make this better.
2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large `n`, so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for `A`, which is easy to code since `A` is tridiagonal.

### Acknowledgements

`lobpcg.py` code was written by Robert Cimrman. Many thanks belong to Andrew Knyazev, the author of the algorithm, for lots of advice and support.

### Examples

Solve  $Ax = \lambda Bx$  with constraints and preconditioning.

```
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = [np.arange(n, dtype=np.float64) + 1]
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1.,  0.,  0., ...,  0.,  0.,  0.],
       [ 0.,  2.,  0., ...,  0.,  0.,  0.],
       [ 0.,  0.,  3., ...,  0.,  0.,  0.],
       ...,
       [ 0.,  0.,  0., ..., 98.,  0.,  0.]])
```

```
[ 0., 0., 0., ..., 0., 99., 0.],
 [ 0., 0., 0., ..., 0., 0., 100.]])
```

Constraints.

```
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```
>>> X = np.random.rand(n, 3)
```

Preconditioner – inverse of A (as an abstract linear operator).

```
>>> invA = spdiags([1./vals[0]], 0, n, n)
>>> def precondition(x):
...     return invA * x
>>> M = LinearOperator(matvec=precond, shape=(n, n), dtype=float)
```

Here, invA could of course have been used directly as a preconditioner. Let us then solve the problem:

```
>>> eigs, vecs = lobpcg(A, X, Y=Y, M=M, tol=1e-4, maxiter=40, largest=False)
>>> eigs
array([ 4., 5., 6.])
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

<code>svds(A[, k, ncv, tol, which, v0, maxiter, ...])</code>	Compute the largest k singular values/vectors for a sparse matrix.
--	--

`scipy.sparse.linalg.svds(A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return_singular_vectors=True)`

Compute the largest k singular values/vectors for a sparse matrix.

**Parameters**

- A** : {sparse matrix, LinearOperator}
  - Array to compute the SVD on, of shape (M, N)
- k** : int, optional
  - Number of singular values and vectors to compute. Must be  $1 \leq k < \min(A.shape)$ .
- ncv** : int, optional
  - The number of Lanczos vectors generated ncv must be greater than k+1 and smaller than n; it is recommended that  $ncv > 2*k$  Default:  $\min(n, \max(2*k + 1, 20))$
- tol** : float, optional
  - Tolerance for singular values. Zero (default) means machine precision.
- which** : str, ['LM' | 'SM'], optional
  - Which k singular values to find:
    - 'LM' : largest singular values
    - 'SM' : smallest singular values
  - New in version 0.12.0.
- v0** : ndarray, optional
  - Starting vector for iteration, of length  $\min(A.shape)$ . Should be an (approximate) left singular vector if  $N > M$  and a right singular vector otherwise.

Default: random  
 New in version 0.12.0.

**maxiter** : int, optional  
 Maximum number of iterations.  
 New in version 0.12.0.

**return\_singular\_vectors** : bool or str, optional

- True: return singular vectors (True) in addition to singular values.

New in version 0.12.0.

- "u": only return the u matrix, without computing vh (if  $N > M$ ).
- "vh": only return the vh matrix, without computing u (if  $N \leq M$ ).

**Returns**

**u** : ndarray, shape=(M, k)  
 New in version 0.16.0.  
 Unitary matrix having left singular vectors as columns. If *return\_singular\_vectors* is "vh", this variable is not computed, and None is returned instead.

**s** : ndarray, shape=(k,)  
 The singular values.

**vt** : ndarray, shape=(k, N)  
 Unitary matrix having right singular vectors as rows. If *return\_singular\_vectors* is "u", this variable is not computed, and None is returned instead.

**Notes**

This is a naive implementation using ARPACK as an eigensolver on  $A.H * A$  or  $A * A.H$ , depending on which one is more efficient.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import svds, eigs
>>> A = csc_matrix([[1, 0, 0], [5, 0, 2], [0, -1, 0], [0, 0, 3]], dtype=float)
>>> u, s, vt = svds(A, k=2)
>>> s
array([ 2.75193379,  5.6059665 ])
>>> np.sqrt(eigs(A.dot(A.T), k=2)[0]).real
array([ 5.6059665 ,  2.75193379])
```

Complete or incomplete LU factorizations

<code>splu(A[, permc_spec, diag_pivot_thresh, ...])</code>	Compute the LU decomposition of a sparse, square matrix.
<code>spilu(A[, drop_tol, fill_factor, drop_rule, ...])</code>	Compute an incomplete LU decomposition for a sparse, square matrix.
<i>SuperLU</i>	LU factorization of a sparse matrix.

`scipy.sparse.linalg.splu(A, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options={})`  
 Compute the LU decomposition of a sparse, square matrix.

**Parameters**

**A** : sparse matrix  
 Sparse matrix to factorize. Should be in CSR or CSC format.

**permc\_spec** : str, optional  
 How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')

- NATURAL: natural ordering.
- MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
- MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T A + A$ .
- COLAMD: approximate minimum degree column ordering

**diag\_pivot\_thresh** : float, optional  
 Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user's guide for details [R394]

**relax** : int, optional  
 Expert option for customizing the degree of relaxing supernodes. See SuperLU user's guide for details [R394]

**panel\_size** : int, optional  
 Expert option for customizing the panel size. See SuperLU user's guide for details [R394]

**options** : dict, optional  
 Dictionary containing additional expert options to SuperLU. See SuperLU user guide [R394] (section 2.4 on the 'Options' argument) for more details. For example, you can specify `options=dict(Equil=False, IterRefine='SINGLE')` to turn equilibration off and perform a single iterative refinement.

**Returns** **invA** : `scipy.sparse.linalg.SuperLU`  
 Object, which has a `solve` method.

**See also:**

**spilu** incomplete LU decomposition

**Notes**

This function uses the SuperLU library.

**References**

[R394]

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]], dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1.,  2.,  3.])
>>> B.solve(A.dot(x))
array([ 1.,  2.,  3.])
```

`scipy.sparse.linalg.spilu`(A, *drop\_tol=None*, *fill\_factor=None*, *drop\_rule=None*, *perm\_spec=None*, *diag\_pivot\_thresh=None*, *relax=None*, *panel\_size=None*, *options=None*)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of A.

**Parameters** **A** : (N, N) array\_like  
 Sparse matrix to factorize  
**drop\_tol** : float, optional

Drop tolerance ( $0 \leq \text{tol} \leq 1$ ) for an incomplete LU decomposition. (default:  $1e-4$ )

**fill\_factor** : float, optional  
Specifies the fill ratio upper bound ( $\geq 1.0$ ) for ILU. (default: 10)

**drop\_rule** : str, optional  
Comma-separated string of drop rules to use. Available rules: `basic`, `prows`, `column`, `area`, `secondary`, `dynamic`, `interp`. (Default: `basic, area`)  
See SuperLU documentation for details.

**Remaining other options**  
Same as for `splu`

**Returns** **invA\_approx** : `scipy.sparse.linalg.SuperLU`  
Object, which has a `solve` method.

**See also:**

**splu** complete LU decomposition

**Notes**

To improve the better approximation to the inverse, you may need to increase `fill_factor` AND decrease `drop_tol`.

This function uses the SuperLU library.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]], dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1.,  2.,  3.])
>>> B.solve(A.dot(x))
array([ 1.,  2.,  3.])
```

**class** `scipy.sparse.linalg.SuperLU`

LU factorization of a sparse matrix.

Factorization is represented as:

$$Pr * A * Pc = L * U$$

To construct these *SuperLU* objects, call the `splu` and `spilu` functions.

**Notes**

New in version 0.14.0.

**Examples**

The LU decomposition can be used to solve matrix equations. Consider:

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1,2,0,4],[1,0,0,1],[1,0,2,1],[2,2,1,0]])
```

This can be solved for a given right-hand side:

```
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([ 1.,  2.,  3.,  4.]
```

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The L and U factors are sparse matrices in CSC format:

```
>>> lu.L.A
array([[ 1. ,  0. ,  0. ,  0. ],
       [ 0. ,  1. ,  0. ,  0. ],
       [ 0. ,  0. ,  1. ,  0. ],
       [ 1. ,  0.5,  0.5,  1. ]])
>>> lu.U.A
array([[ 2.,  0.,  1.,  4.],
       [ 0.,  2.,  1.,  1.],
       [ 0.,  0.,  1.,  1.],
       [ 0.,  0.,  0., -5.]])
```

The permutation matrices can be constructed:

```
>>> Pr = csc_matrix((4, 4))
>>> Pr[lu.perm_r, np.arange(4)] = 1
>>> Pc = csc_matrix((4, 4))
>>> Pc[np.arange(4), lu.perm_c] = 1
```

We can reassemble the original matrix:

```
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1.,  2.,  0.,  4.],
       [ 1.,  0.,  0.,  1.],
       [ 1.,  0.,  2.,  1.],
       [ 2.,  2.,  1.,  0.]])
```

### Attributes

<i>shape</i>	Shape of the original matrix as a tuple of ints.
<i>nnz</i>	Number of nonzero elements in the matrix.
<i>perm_c</i>	Permutation Pc represented as an array of indices.
<i>perm_r</i>	Permutation Pr represented as an array of indices.
<i>L</i>	Lower triangular factor with unit diagonal as a <i>scipy.sparse.csc_matrix</i> .
<i>U</i>	Upper triangular factor as a <i>scipy.sparse.csc_matrix</i> .

### SuperLU. **shape**

Shape of the original matrix as a tuple of ints.

SuperLU.**nnz**

Number of nonzero elements in the matrix.

SuperLU.**perm\_c**

Permutation Pc represented as an array of indices.

The column permutation matrix can be reconstructed via:

```
>>> Pc = np.zeros((n, n))
>>> Pc[np.arange(n), perm_c] = 1
```

SuperLU.**perm\_r**

Permutation Pr represented as an array of indices.

The row permutation matrix can be reconstructed via:

```
>>> Pr = np.zeros((n, n))
>>> Pr[perm_r, np.arange(n)] = 1
```

SuperLU.**L**

Lower triangular factor with unit diagonal as a *scipy.sparse.csc\_matrix*.

New in version 0.14.0.

SuperLU.**U**

Upper triangular factor as a *scipy.sparse.csc\_matrix*.

New in version 0.14.0.

### Methods

<i>solve</i> (rhs[, trans])	Solves linear system of equations with one or several right-hand sides.
-----------------------------	---

SuperLU.**solve** (rhs[, trans])

Solves linear system of equations with one or several right-hand sides.

**Parameters** **rhs** : ndarray, shape (n,) or (n, k)  
 Right hand side(s) of equation  
**trans** : {'N', 'T', 'H'}, optional  
 Type of system to solve:

```
'N':  A   * x == rhs  (default)
'T':  A^T * x == rhs
'H':  A^H * x == rhs
```

**Returns** **x** : ndarray, shape rhs.shape  
 i.e., normal, transposed, and hermitian conjugate.  
 Solution vector(s)

## 5.22.6 Exceptions

<i>ArpackNoConvergence</i> (msg, eigenvalues, ...)	ARPACK iteration did not converge
<i>ArpackError</i> (info[, infodict])	ARPACK error

**exception** *scipy.sparse.linalg.ArpackNoConvergence* (msg, eigenvalues, eigenvectors)  
 ARPACK iteration did not converge

*Attributes*

eigenvalues	(ndarray) Partial result. Converged eigenvalues.
eigenvectors	(ndarray) Partial result. Converged eigenvectors.

**exception** `scipy.sparse.linalg.ArpackError` (*info*, *infodict*={*c*: {0: 'Normal exit.', 1: 'Maximum number of iterations taken. All possible eigenvalues of OP has been found. ARPACK error

## 5.23 Compressed Sparse Graph Routines (`scipy.sparse.csgraph`)

Fast graph algorithms based on sparse matrix representations.

### 5.23.1 Contents

<code>connected_components(csgraph[, directed, ...])</code>	Analyze the connected components of a sparse graph
<code>laplacian(csgraph[, normed, return_diag, ...])</code>	Return the Laplacian matrix of a directed graph.
<code>shortest_path(csgraph[, method, directed, ...])</code>	Perform a shortest-path graph search on a positive directed or undirected graph.
<code>dijkstra(csgraph[, directed, indices, ...])</code>	Dijkstra algorithm using Fibonacci Heaps
<code>floyd_warshall(csgraph[, directed, ...])</code>	Compute the shortest path lengths using the Floyd-Warshall algorithm
<code>bellman_ford(csgraph[, directed, indices, ...])</code>	Compute the shortest path lengths using the Bellman-Ford algorithm.
<code>johnson(csgraph[, directed, indices, ...])</code>	Compute the shortest path lengths using Johnson's algorithm.
<code>breadth_first_order(csgraph, i_start[, ...])</code>	Return a breadth-first ordering starting with specified node.
<code>depth_first_order(csgraph, i_start[, ...])</code>	Return a depth-first ordering starting with specified node.
<code>breadth_first_tree(csgraph, i_start[, directed])</code>	Return the tree generated by a breadth-first search
<code>depth_first_tree(csgraph, i_start[, directed])</code>	Return a tree generated by a depth-first search.
<code>minimum_spanning_tree(csgraph[, overwrite])</code>	Return a minimum spanning tree of an undirected graph
<code>reverse_cuthill_mckee(graph[, symmetric_mode])</code>	Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.
<code>maximum_bipartite_matching(graph[, perm_type])</code>	Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.
<code>structural_rank(graph)</code>	Compute the structural rank of a graph (matrix) with a given sparsity pattern.
<code>NegativeCycleError</code>	

`scipy.sparse.csgraph.connected_components` (*csgraph*, *directed=True*, *connection='weak'*, *return\_labels=True*)

Analyze the connected components of a sparse graph

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix

The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

**directed** : bool, optional

If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

**connection** : str, optional

['weak'|'strong']. For directed graphs, the type of connection to use. Nodes i and j are strongly connected if a path exists both from i to j and from j to

i. Nodes i and j are weakly connected if only one of these paths exists. If `directed == False`, this keyword is not referenced.

**return\_labels** : bool, optional  
If True (default), then return the labels for each of the connected components.

**Returns**

**n\_components**: int  
The number of connected components.

**labels**: ndarray  
The length-N array of labels of the connected components.

### References

[R314]

`scipy.sparse.csgraph.laplacian` (*csgraph*, *normed=False*, *return\_diag=False*, *use\_out\_degree=False*)

Return the Laplacian matrix of a directed graph.

**Parameters**

**csgraph** : array\_like or sparse matrix, 2 dimensions  
compressed-sparse graph, with shape (N, N).

**normed** : bool, optional  
If True, then compute normalized Laplacian.

**return\_diag** : bool, optional  
If True, then also return an array related to vertex degrees.

**use\_out\_degree** : bool, optional  
If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

**Returns**

**lap** : ndarray or sparse matrix  
The N x N laplacian matrix of *csgraph*. It will be a numpy array (dense) if the input was dense, or a sparse matrix otherwise.

**diag** : ndarray, optional  
The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

### Notes

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

### Examples

```
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```

```
scipy.sparse.csgraph.shortest_path(csgraph, method='auto', directed=True,
                                     return_predecessors=False, unweighted=False,
                                     overwrite=False, indices=None)
```

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters**

- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
- method** : string ['auto'|'FW'|'D'], optional  
Algorithm to use for shortest paths. Options are:
  - 'auto'** – (default) select the best among 'FW', 'D', 'BF', or 'J' based on the input data.
  - 'FW'** – *Floyd-Warshall algorithm. Computational cost is approximately  $O[N^3]$ . The input csgraph will be converted to a dense representation.*
  - 'D'** – *Dijkstra's algorithm with Fibonacci heaps. Computational cost is approximately  $O[N(N*k + N*\log(N))]$ , where k is the average number of connected edges per node. The input csgraph will be converted to a csr representation.*
  - 'BF'** – *Bellman-Ford algorithm. This algorithm can be used when weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately  $O[N(N^2*k)]$ , where k is the average number of connected edges per node. The input csgraph will be converted to a csr representation.*
  - 'J'** – *Johnson's algorithm. Like the Bellman-Ford algorithm, Johnson's algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra's algorithm for faster computation.*
- directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix
- unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- overwrite** : bool, optional  
If True, overwrite csgraph with the result. This applies only if method == 'FW' and csgraph is a dense, c-ordered array with dtype=float64.
- indices** : array\_like or int, optional  
If specified, only compute the paths for the points at the given indices. Incompatible with method == 'FW'.

**Returns**

- dist\_matrix** : ndarray

The  $N \times N$  matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point  $i$  to point  $j$  along the graph.

**predecessors** : ndarray

Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`

**Raises**

**NegativeCycleError:**

if there are negative cycles in the graph

### Notes

As currently implemented, Dijkstra's algorithm and Johnson's algorithm do not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are non-equal edges, `method='D'` may yield an incorrect result.

`scipy.sparse.csgraph.dijkstra(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False, limit=np.inf)`

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

### Parameters

**csgraph** : array, matrix, or sparse matrix, 2 dimensions

The  $N \times N$  array of non-negative distances representing the input graph.

**directed** : bool, optional

If True (default), then find the shortest path on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`

**indices** : array\_like or int, optional

if specified, only compute the paths for the points at the given indices.

**return\_predecessors** : bool, optional

If True, return the size  $(N, N)$  predecessor matrix

**unweighted** : bool, optional

If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**limit** : float, optional

The maximum distance to calculate, must be  $\geq 0$ . Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance  $> \text{limit}$ . For such pairs, the distance will be equal to `np.inf` (i.e., not connected).

### Returns

**dist\_matrix** : ndarray

New in version 0.14.0.  
The matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point  $i$  to point  $j$  along the graph.

**predecessors** : ndarray

Returned only if `return_predecessors == True`. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`

*Notes*

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are not equal and both are nonzero, setting `directed=False` will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford’s algorithm or Johnson’s algorithm.

`scipy.sparse.csgraph.floyd_warshall` (*csgraph*, *directed=True*, *return\_predecessors=False*, *unweighted=False*, *overwrite=False*)

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

- Parameters**
- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
  - directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`
  - return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix
  - unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
  - overwrite** : bool, optional  
If True, overwrite `csgraph` with the result. This applies only if `csgraph` is a dense, c-ordered array with `dtype=float64`.
- Returns**
- dist\_matrix** : ndarray  
The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.
  - predecessors** : ndarray  
Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`
- Raises**
- NegativeCycleError**:  
if there are negative cycles in the graph

`scipy.sparse.csgraph.bellman_ford` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra’s algorithm may be faster.

New in version 0.11.0.

- Parameters**
- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
  - directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`

**indices** : array\_like or int, optional  
if specified, only compute the paths for the points at the given indices.

**return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix

**unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns** **dist\_matrix** : ndarray  
The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point `i` to point `j` along the graph.

**predecessors** : ndarray  
Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row `i` of the predecessor matrix contains information on the shortest paths from point `i`: each entry `predecessors[i, j]` gives the index of the previous node in the path from point `i` to point `j`. If no path exists between point `i` and `j`, then `predecessors[i, j] = -9999`

**Raises** **NegativeCycleError**:  
if there are negative cycles in the graph

### Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

```
scipy.sparse.csgraph.johnson(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)
```

Compute the shortest path lengths using Johnson's algorithm.

Johnson's algorithm combines the Bellman-Ford algorithm and Dijkstra's algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, `dijkstra()` may be faster.

New in version 0.11.0.

**Parameters** **csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.

**directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point `i` to point `j` along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point `i` to `j` along `csgraph[i, j]` or `csgraph[j, i]`

**indices** : array\_like or int, optional  
if specified, only compute the paths for the points at the given indices.

**return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix

**unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns** **dist\_matrix** : ndarray  
The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point `i` to point `j` along the graph.

**predecessors** : ndarray  
Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row `i` of the predecessor matrix contains information on the shortest paths from point

**Raises** **NegativeCycleError:**  
*i*: each entry predecessors[*i*, *j*] gives the index of the previous node in the path from point *i* to point *j*. If no path exists between point *i* and *j*, then predecessors[*i*, *j*] = -9999  
 if there are negative cycles in the graph

**Notes**

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

```
scipy.sparse.csgraph.breadth_first_order(csgraph, i_start, directed=True, return_predecessors=True)
```

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix  
 The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

**i\_start** : int  
 The index of starting node.

**directed** : bool, optional  
 If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths csgraph[*i*, *j*]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along csgraph[*i*, *j*] or csgraph[*j*, *i*].

**return\_predecessors** : bool, optional  
 If True (default), then return the predecessor array (see below).

**Returns** **node\_array** : ndarray, one dimension  
 The breadth-first list of nodes, starting with specified node. The length of node\_array is the number of nodes reachable from the specified node.

**predecessors** : ndarray, one dimension  
 Returned only if return\_predecessors is True. The length-N list of predecessors of each node in a breadth-first tree. If node *i* is in the tree, then its parent is given by predecessors[*i*]. If node *i* is not in the tree (and for the parent node) then predecessors[*i*] = -9999.

```
scipy.sparse.csgraph.depth_first_order(csgraph, i_start, directed=True, return_predecessors=True)
```

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix  
 The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

**i\_start** : int  
 The index of starting node.

**directed** : bool, optional  
 If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths csgraph[*i*, *j*]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along csgraph[*i*, *j*] or csgraph[*j*, *i*].

**return\_predecessors** : bool, optional

**Returns**

**node\_array** : ndarray, one dimension  
If True (default), then return the predecessor array (see below).  
The depth-first list of nodes, starting with specified node. The length of node\_array is the number of nodes reachable from the specified node.

**predecessors** : ndarray, one dimension  
Returned only if return\_predecessors is True. The length-N list of predecessors of each node in a depth-first tree. If node *i* is in the tree, then its parent is given by predecessors[*i*]. If node *i* is not in the tree (and for the parent node) then predecessors[*i*] = -9999.

scipy.sparse.csgraph.breadth\_first\_tree (csgraph, i\_start, directed=True)

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

**Parameters**

**csgraph** : array\_like or sparse matrix  
The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

**i\_start** : int  
The index of starting node.

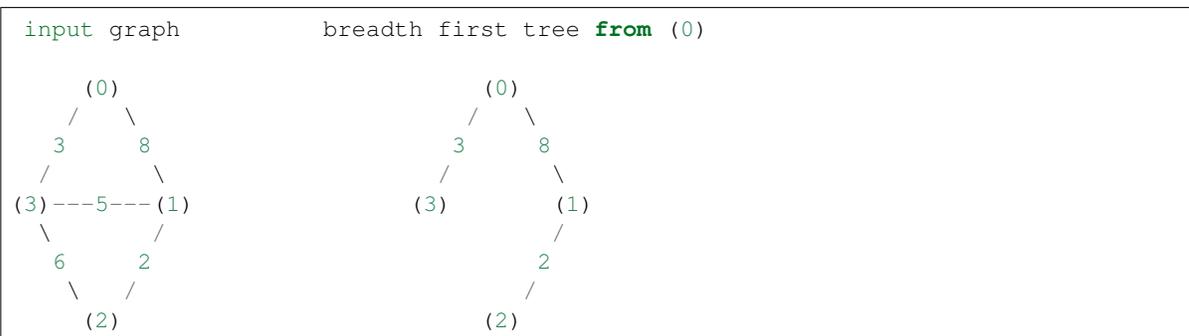

**directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths csgraph[*i*, *j*]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along csgraph[*i*, *j*] or csgraph[*j*, *i*].

**Returns**

**csree** : csr matrix  
The N x N directed compressed-sparse representation of the breadth-first tree drawn from csgraph, starting at the specified node.

### Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                 [0, 0, 2, 5],
...                 [0, 0, 0, 6],
...                 [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],

```

```
[0, 0, 2, 0],
[0, 0, 0, 0],
[0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.

`scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)`

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

**Parameters**

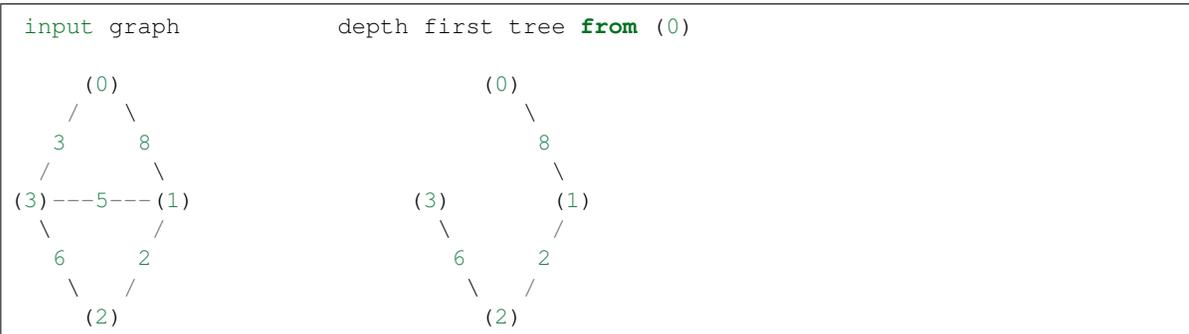

- csgraph** : array\_like or sparse matrix  
The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** : int  
The index of starting node.
- directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

**Returns**

- csmtree** : csr matrix  
The N x N directed compressed-sparse representation of the depth- first tree drawn from csgraph, starting at the specified node.

### Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                 [0, 0, 2, 5],
...                 [0, 0, 0, 6],
...                 [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
```

```
[0, 0, 0, 6],
[0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

`scipy.sparse.csgraph.minimum_spanning_tree(csgraph, overwrite=False)`

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

**Parameters**

- csgraph** : array\_like or sparse matrix, 2 dimensions  
The N x N matrix representing an undirected graph over N nodes (see notes below).
- overwrite** : bool, optional  
if true, then parts of the input graph will be overwritten for efficiency.

**Returns**

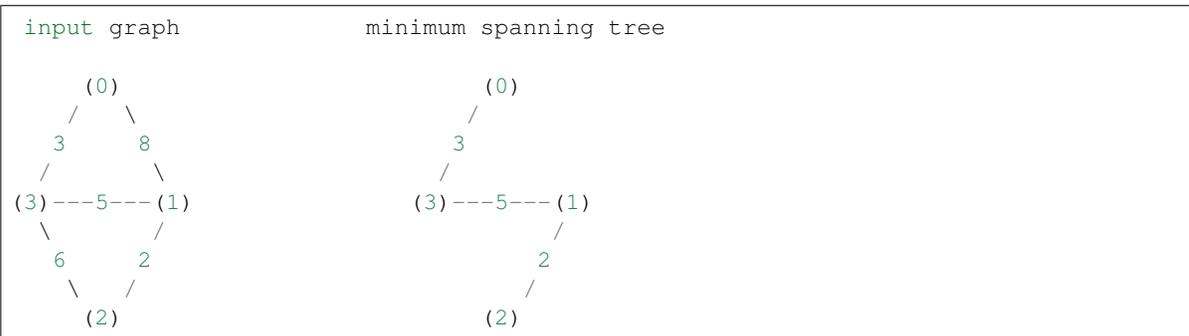

- span\_tree** : csr matrix  
The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

### Notes

This routine uses undirected graphs as input and output. That is, if `graph[i, j]` and `graph[j, i]` are both zero, then nodes `i` and `j` do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

### Examples

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
```

```
[0, 0, 2, 5],
[0, 0, 0, 0],
[0, 0, 0, 0]])
```

`scipy.sparse.csgraph.reverse_cuthill_mckee` (*graph*, *symmetric\_mode=False*)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, `symmetric_mode=False`, that the input matrix is not symmetric and works on the matrix  $A+A.T$ . If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set `symmetric_mode=True`.

**Parameters**

- graph** : sparse matrix  
Input sparse in CSC or CSR sparse matrix format.
- symmetric\_mode** : bool, optional  
Is input matrix guaranteed to be symmetric.

**Returns**

- perm** : ndarray  
Array of permuted row and column indices.

**Notes**

New in version 0.15.0.

**References**

E. Cuthill and J. McKee, “Reducing the Bandwidth of Sparse Symmetric Matrices”, ACM ‘69 Proceedings of the 1969 24th national conference, (1969).

`scipy.sparse.csgraph.maximum_bipartite_matching` (*graph*, *perm\_type='row'*)

Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.

Such a permutation is always possible provided that the matrix is nonsingular. This function looks at the structure of the matrix only. The input matrix will be converted to CSC matrix format if necessary.

**Parameters**

- graph** : sparse matrix  
Input sparse in CSC format
- perm\_type** : str, {'row', 'column'}  
Type of permutation to generate.

**Returns**

- perm** : ndarray  
Array of row or column permutations.

**Notes**

This function relies on a maximum cardinality bipartite matching algorithm based on a breadth-first search (BFS) of the underlying graph.

New in version 0.15.0.

**References**

`scipy.sparse.csgraph.structural_rank` (*graph*)

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

**Parameters**

- graph** : sparse matrix  
Input sparse matrix.

**Returns**     **rank** : int  
                   The structural rank of the sparse graph.  
 New in version 0.19.0.

`scipy.sparse.csgraph.construct_dist_matrix` (*graph*, *predecessors*, *directed=True*, *null\_value=np.inf*)

Construct distance matrix from a predecessor matrix

New in version 0.11.0.

**Parameters**   **graph** : array\_like or sparse  
                   The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.

**predecessors** : array\_like  
                   The N x N matrix of predecessors of each node (see Notes below).

**directed** : bool, optional  
                   If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then operate on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.

**null\_value** : bool, optional  
                   value to use for distances between unconnected nodes. Default is `np.inf`

**Returns**       **dist\_matrix** : ndarray  
                   The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

### Notes

The predecessor matrix is of the form returned by `graph_shortest_path`. Row *i* of the predecessor matrix contains information on the shortest paths from point *i*: each entry `predecessors[i, j]` gives the index of the previous node in the path from point *i* to point *j*. If no path exists between point *i* and *j*, then `predecessors[i, j] = -9999`

`scipy.sparse.csgraph.csgraph_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*, *infinity\_null=True*)

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

**Parameters**   **graph** : array\_like

Input graph. Shape should be (n\_nodes, n\_nodes).  
**null\_value** : float or None (optional)  
 Value that denotes non-edges in the graph. Default is zero.  
**infinity\_null** : bool  
 If True (default), then infinite entries (both positive and negative) are treated as null edges.  
**nan\_null** : bool  
 If True (default), then NaN entries are treated as non-edges  
**Returns** **csgraph** : csr\_matrix  
 Compressed sparse representation of graph,

`scipy.sparse.csgraph.csgraph_from_masked(graph)`  
 Construct a CSR-format graph from a masked array.

New in version 0.11.0.

**Parameters** **graph** : MaskedArray  
**Returns** **csgraph** : csr\_matrix  
 Input graph. Shape should be (n\_nodes, n\_nodes).  
 Compressed sparse representation of graph,

`scipy.sparse.csgraph.csgraph_masked_from_dense(graph, null_value=0, nan_null=True, infinity_null=True, copy=True)`  
 Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

**Parameters** **graph** : array\_like  
 Input graph. Shape should be (n\_nodes, n\_nodes).  
**null\_value** : float or None (optional)  
 Value that denotes non-edges in the graph. Default is zero.  
**infinity\_null** : bool  
 If True (default), then infinite entries (both positive and negative) are treated as null edges.  
**nan\_null** : bool  
 If True (default), then NaN entries are treated as non-edges  
**Returns** **csgraph** : MaskedArray  
 masked array representation of graph

`scipy.sparse.csgraph.csgraph_to_dense(csgraph, null_value=0)`  
 Convert a sparse graph representation to a dense representation

New in version 0.11.0.

**Parameters** **csgraph** : csr\_matrix, csc\_matrix, or lil\_matrix  
 Sparse representation of a graph.  
**null\_value** : float, optional  
 The value used to indicate null edges in the dense representation. Default is 0.  
**Returns** **graph** : ndarray  
 The dense representation of the sparse graph.

**Notes**

For normal sparse graph representations, calling `csgraph_to_dense` with `null_value=0` produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in `scipy.sparse` will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we'll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```

>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 5],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
       [0., 0.]])

```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default `scipy.sparse` behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let's look at the example of a two-node directed graph, connected by an edge of weight zero:

```

>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[ inf,  0.],
       [ inf,  inf]])

```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

`scipy.sparse.csgraph.csgraph_to_masked(csgraph)`

Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

**Parameters** **csgraph** : `csr_matrix`, `csc_matrix`, or `lil_matrix`

**Returns** **graph** : `MaskedArray` Sparse representation of a graph.

The masked dense representation of the sparse graph.

`scipy.sparse.csgraph.reconstruct_path(csgraph, predecessors, directed=True)`

Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

**Parameters** **csgraph** : `array_like` or sparse matrix

The  $N \times N$  matrix representing the directed or undirected graph from which the predecessors are drawn.

**predecessors** : `array_like`, one dimension

The length- $N$  array of indices of predecessors for the tree. The index of the parent of node  $i$  is given by `predecessors[i]`.

**directed** : `bool`, optional

If `True` (default), then operate on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If `False`, then operate on an undirected

**Returns** `cstree` : csr matrix  
 graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`.  
 The  $N \times N$  directed compressed-sparse representation of the tree drawn from `csgraph` which is encoded by the predecessor list.

### 5.23.2 Graph Representations

This module uses graphs which are stored in a matrix format. A graph with  $N$  nodes can be represented by an  $(N \times N)$  adjacency matrix  $G$ . If there is a connection from node  $i$  to node  $j$ , then  $G[i, j] = w$ , where  $w$  is the weight of the connection. For nodes  $i$  and  $j$  which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by  $G[i, j] = 0$ , infinity, or NaN.
- for dense masked representations (of type `np.ma.MaskedArray`), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```

>>> G_dense = np.array([[0, 2, 1],
...                    [2, 0, 0],
...                    [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)
  
```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```

>>> G2_data = np.array([[np.inf, 2, 0 ],
...                    [2, np.inf, np.inf],
...                    [0, np.inf, np.inf]])
  
```

```

... [0, np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([ 2.,  0.,  2.,  0.])

```

Here we have used a utility routine from the `csgraph` submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

## Directed vs. Undirected

Matrices may represent either directed or undirected graphs. This is specified throughout the `csgraph` module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node  $i$  to node  $j$  can be accomplished over the edge  $G[i, j]$ , but not the edge  $G[j, i]$ . In a non-directed graph, traversal from node  $i$  to node  $j$  can be accomplished over either  $G[i, j]$  or  $G[j, i]$ . If both edges are not null, and the two have unequal weights, then the smaller of the two is used. Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘directed’ keyword is set to `True` or `False`. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either `scipy.sparse` representations (`csr`, `csc`, or `lil` format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.

## 5.24 Spatial algorithms and data structures (`scipy.spatial`)

### 5.24.1 Nearest-neighbor Queries

<code>KDTree</code> ( <code>data</code> [, <code>leafsize</code> ])	kd-tree for quick nearest-neighbor lookup
<code>cKDTree</code>	kd-tree for quick nearest-neighbor lookup
<code>distance</code>	
<code>Rectangle</code> ( <code>maxes</code> , <code>mins</code> )	Hyperrectangle class.

**class** `scipy.spatial.KDTree`(`data`, `leafsize=10`)  
kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of  $k$ -dimensional points which can be used to rapidly look up the nearest neighbors of any point.

**Parameters**

- data** : (N,K) array\_like  
The data points to be indexed. This array is not copied, and so modifying this data will result in bogus results.
- leafsize** : int, optional  
The number of points at which the algorithm switches over to brute-force. Has to be positive.

**Raises**

- RuntimeError**  
The maximum recursion limit can be exceeded for large data sets. If this happens, either increase the value for the `leafsize` parameter or increase the recursion limit by:

```
>>> import sys
>>> sys.setrecursionlimit(10000)
```

See also:

**cKDTree** Implementation of *KDTree* in Cython

**Notes**

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the *r* closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the *r* approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

The tree also supports all-neighbors queries, both with arrays of points and with other kd-trees. These do use a reasonably efficient algorithm, but the kd-tree is not necessarily the best data structure for this sort of calculation.

**Methods**

<code>count_neighbors(other, r[, p])</code>	Count how many nearby pairs can be formed.
<code>innernode(split_dim, split, less, greater)</code>	
<code>leafnode(idx)</code>	
<code>node</code>	
<code>query(x[, k, eps, p, distance_upper_bound])</code>	Query the kd-tree for nearest neighbors
<code>query_ball_point(x, r[, p, eps])</code>	Find all points within distance <i>r</i> of point(s) <i>x</i> .
<code>query_ball_tree(other, r[, p, eps])</code>	Find all pairs of points whose distance is at most <i>r</i>
<code>query_pairs(r[, p, eps])</code>	Find all pairs of points within a distance.
<code>sparse_distance_matrix(other, max_distance)</code>	Compute a sparse distance matrix

`KDTree.count_neighbors` (*other*, *r*, *p*=2.0)

Count how many nearby pairs can be formed.

Count the number of pairs (*x*<sub>1</sub>,*x*<sub>2</sub>) can be formed, with *x*<sub>1</sub> drawn from self and *x*<sub>2</sub> drawn from *other*, and where `distance(x1, x2, p) <= r`. This is the “two-point correlation” described in Gray and Moore 2000, “N-body problems in statistical learning”, and the code here is based on their algorithm.

**Parameters**

- other** : KDTree instance  
The other tree to draw points from.
- r** : float or one-dimensional array of floats  
The radius to produce a count for. Multiple radii are searched with a single tree traversal.
- p** : float, 1<=p<=infinity, optional  
Which Minkowski p-norm to use

**Returns**

- result** : int or 1-D array of ints  
The number of pairs. Note that this is internally stored in a numpy int, and so may overflow if very large (2e9).

`KDTree.query(x, k=1, eps=0, p=2, distance_upper_bound=inf)`

Query the kd-tree for nearest neighbors

**Parameters**

- x** : array\_like, last dimension self.m  
An array of points to query.
- k** : int, optional  
The number of nearest neighbors to return.
- eps** : nonnegative float, optional  
Return approximate nearest neighbors; the kth returned value is guaranteed to be no further than (1+eps) times the distance to the real kth nearest neighbor.
- p** : float,  $1 \leq p \leq \text{infinity}$ , optional  
Which Minkowski p-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance
- distance\_upper\_bound** : nonnegative float, optional  
Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.

**Returns**

- d** : float or array of floats  
The distances to the nearest neighbors. If x has shape tuple+(self.m,), then d has shape tuple if k is one, or tuple+(k,) if k is larger than one. Missing neighbors (e.g. when  $k > n$  or `distance_upper_bound` is given) are indicated with infinite distances. If k is None, then d is an object array of shape tuple, containing lists of distances. In either case the hits are sorted by distance (nearest first).
- i** : integer or array of integers  
The locations of the neighbors in self.data. i is the same shape as d.

### Examples

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = spatial.KDTree(list(zip(x.ravel(), y.ravel())))
>>> tree.data
array([[0, 2],
       [0, 3],
       [0, 4],
       [0, 5],
       [0, 6],
       [0, 7],
       [1, 2],
       [1, 3],
       [1, 4],
       [1, 5],
       [1, 6],
       [1, 7],
       [2, 2],
       [2, 3],
       [2, 4],
       [2, 5],
       [2, 6],
       [2, 7],
       [3, 2],
       [3, 3],
       [3, 4],
```

```

        [3, 5],
        [3, 6],
        [3, 7],
        [4, 2],
        [4, 3],
        [4, 4],
        [4, 5],
        [4, 6],
        [4, 7]])
>>> pts = np.array([[0, 0], [2.1, 2.9]])
>>> tree.query(pts)
(array([ 2.          ,  0.14142136]), array([ 0, 13]))
>>> tree.query(pts[0])
(2.0, 0)

```

`KDTree.query_ball_point` ( $x$ ,  $r$ ,  $p=2.0$ ,  $eps=0$ )

Find all points within distance  $r$  of point(s)  $x$ .

**Parameters**

- x** : array\_like, shape tuple + (self.m.)  
The point or points to search for neighbors of.
- r** : positive float  
The radius of points to return.
- p** : float, optional  
Which Minkowski p-norm to use. Should be in the range [1, inf].
- eps** : nonnegative float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + eps)$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + eps)$ .

**Returns**

- results** : list or array of lists  
If  $x$  is a single point, returns a list of the indices of the neighbors of  $x$ . If  $x$  is an array of points, returns an object array of shape tuple containing lists of neighbors.

### Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a KDTree and using `query_ball_tree`.

### Examples

```

>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 0:5]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.KDTree(points)
>>> tree.query_ball_point([2, 0], 1)
[5, 10, 11, 15]

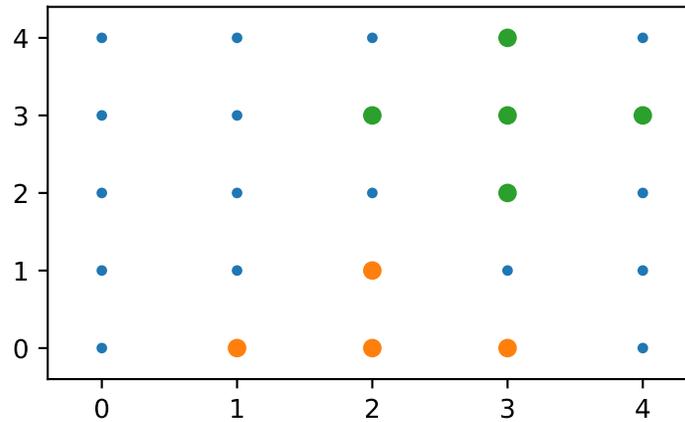

```

Query multiple points and plot the results:

```

>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point([[2, 0], [3, 3]], 1):
...     nearby_points = points[results]
...     plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()

```

`KDTree.query_ball_tree` (*other*, *r*, *p*=2.0, *eps*=0)

Find all pairs of points whose distance is at most *r*

**Parameters**

- other** : KDTree instance  
The tree containing points to search against.
- r** : float  
The maximum distance, has to be positive.
- p** : float, optional  
Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ .
- eps** : float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

**Returns**

- results** : list of lists  
For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

`KDTree.query_pairs` (*r*, *p*=2.0, *eps*=0)

Find all pairs of points within a distance.

**Parameters**

- r** : positive float  
The maximum distance.
- p** : float, optional  
Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ .
- eps** : float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

**Returns**

- results** : set  
Set of pairs  $(i, j)$ , with  $i < j$ , for which the corresponding positions are close.

`KDTree.sparse_distance_matrix` (*other*, *max\_distance*, *p=2.0*)

Compute a sparse distance matrix

Computes a distance matrix between two KDTrees, leaving as zero any distance greater than *max\_distance*.

**Parameters**    **other** : KDTree  
                   **max\_distance** : positive float

**Returns**        **p** : float, optional  
                   **result** : dok\_matrix

Sparse matrix representing the results in “dictionary of keys” format.

**class** `scipy.spatial.cKDTree`

kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary trie, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the *r* closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the *r* approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

**Parameters**    **data** : array\_like, shape (n,m)

The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with `copy_data=True`.

**leafsize** : positive int, optional

The number of points at which the algorithm switches over to brute-force. Default: 16.

**compact\_nodes** : bool, optional

If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.

**copy\_data** : bool, optional

If True the data is always copied to protect the kd-tree against data corruption. Default: False.

**balanced\_tree** : bool, optional

If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.

**boxsize** : array\_like or scalar, optional

Apply a m-d toroidal topology to the KDTree.. The topology is generated by  $x_i + n_i L_i$  where  $n_i$  are integers and  $L_i$  is the boxsize along i-th dimension. The input data shall be wrapped into  $[0, L_i)$ . A ValueError is raised if any of the data is outside of this bound.

**See also:****KDTree** Implementation of *cKDTree* in pure Python**Attributes**

<code>data</code>	(ndarray, shape (n,m)) The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with <i>copy_data=True</i> .
<code>leaf-size</code>	(positive int) The number of points at which the algorithm switches over to brute-force.
<code>m</code>	(int) The dimension of a single data-point.
<code>n</code>	(int) The number of data points.
<code>maxes</code>	(ndarray, shape (m,)) The maximum value in each dimension of the n data points.
<code>mins</code>	(ndarray, shape (m,)) The minimum value in each dimension of the n data points.
<code>tree</code>	(object, class <i>cKDTreeNode</i> ) This class exposes a Python view of the root node in the <i>cKDTree</i> object.
<code>size</code>	(int) The number of nodes in the tree.

**Methods**

<code>count_neighbors(self, other, r[, p, ...])</code>	Count how many nearby pairs can be formed.
<code>query(self, x[, k, eps, p, ...])</code>	Query the kd-tree for nearest neighbors
<code>query_ball_point(self, x, r[, p, eps])</code>	Find all points within distance r of point(s) x.
<code>query_ball_tree(self, other, r[, p, eps])</code>	Find all pairs of points whose distance is at most r
<code>query_pairs(self, r[, p, eps])</code>	Find all pairs of points whose distance is at most r.
<code>sparse_distance_matrix(self, other, max_distance)</code>	Compute a sparse distance matrix

`cKDTree.count_neighbors` (*self, other, r, p=2., weights=None, cumulative=True*)

Count how many nearby pairs can be formed. (pair-counting)

Count the number of pairs (x1,x2) can be formed, with x1 drawn from *self* and x2 drawn from *other*, and where `distance(x1, x2, p) <= r`.

Data points on *self* and *other* are optionally weighted by the *weights* argument. (See below)

The algorithm we implement here is based on [R401]. See notes for further discussion.

**Parameters** **other** : *cKDTree* instance

The other tree to draw points from, can be the same tree as *self*.

**r** : float or one-dimensional array of floats

The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative (*cumulative=False*), *r* defines the edges of the bins, and must be non-decreasing.

**p** : float, optional

$1 \leq p \leq \infty$ . Which Minkowski p-norm to use. Default 2.0.

**weights** : tuple, array\_like, or None, optional

If None, the pair-counting is unweighted. If given as a tuple, `weights[0]` is the weights of points in *self*, and `weights[1]` is the weights of points in *other*; either can be None to indicate the points are unweighted. If given as an array\_like, *weights* is the weights of points in *self* and *other*. For this to make sense, *self* and *other* must be the same tree. If *self* and *other* are two different trees, a `ValueError` is raised. Default: None

**cumulative** : bool, optional  
 Whether the returned counts are cumulative. When `cumulative` is set to `False` the algorithm is optimized to work with a large number of bins (>10) specified by `r`. When `cumulative` is set to `True`, the algorithm is optimized to work with a small number of `r`. Default: `True`.

**Returns** **result** : scalar or 1-D array  
 The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If `cumulative` is `False`, `result[i]` contains the counts with `(-inf if i == 0 else r[i-1]) < R <= r[i]`

**Notes**

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of `D` measures the clustering signal in `D`. [R402]

- For example, given the position of two sets of objects,
- objects `D` (data) contains the clustering signal, and
  - objects `R` (random) that contains no signal,

$$\xi(r) = \frac{\langle D, D \rangle - 2f \langle D, R \rangle + f^2 \langle R, R \rangle}{f^2 \langle R, R \rangle},$$

where the brackets represents counting pairs between two data sets in a finite bin around `r` (distance), corresponding to setting `cumulative=False`, and `f = float(len(D)) / float(len(R))` is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [R401]. We switch between two different pair-cumulation scheme depending on the setting of `cumulative`. The computing time of the method we use when for `cumulative == False` does not scale with the total number of bins. The algorithm for `cumulative == True` scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [R405].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([R403], section 2.2), or to properly calculate the average of data per distance bin (e.g. [R404], section 2.1 on redshift).

`ckdtree.query(self, x, k=1, eps=0, p=2, distance_upper_bound=np.inf, n_jobs=1)`

Query the kd-tree for nearest neighbors

**Parameters** **x** : array\_like, last dimension self.m  
 An array of points to query.

**k** : list of integer or integer  
 The list of k-th nearest neighbors to return. If `k` is an integer it is treated as a list of `[1, ... k]` (`range(1, k+1)`). Note that the counting starts from 1.

**eps** : non-negative float  
 Return approximate nearest neighbors; the k-th returned value is guaranteed to be no further than `(1+eps)` times the distance to the real k-th nearest neighbor.

**p** : float, `1 <= p <= infinity`

Which Minkowski  $p$ -norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance

**distance\_upper\_bound** : nonnegative float

Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.

**n\_jobs** : int, optional

Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.

**Returns**

**d** : array of floats

The distances to the nearest neighbors. If  $x$  has shape `tuple+(self.m,)`, then  $d$  has shape `tuple+(k,)`. When  $k == 1$ , the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances.

**i** : ndarray of ints

The locations of the neighbors in `self.data`. If  $x$  has shape `tuple+(self.m,)`, then  $i$  has shape `tuple+(k,)`. When  $k == 1$ , the last dimension of the output is squeezed. Missing neighbors are indicated with `self.n`.

### Notes

If the KD-Tree is periodic, the position  $x$  is wrapped into the box.

When the input  $k$  is a list, a query for `arange(max(k))` is performed, but only columns that store the requested values of  $k$  are preserved. This is implemented in a manner that reduces memory usage.

### Examples

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = cKDTree(np.c_[x.ravel(), y.ravel()])
```

To query the nearest neighbours and return squeezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[ 2.          0.14142136] [ 0 13]
```

To query the nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1])
>>> print(dd, ii)
[[ 2.          ]
 [ 0.14142136]] [[ 0]
 [13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[2])
>>> print(dd, ii)
[[ 2.23606798]
 [ 0.90553851]] [[ 6]
 [12]]
```

To query the first and second nearest neighbours, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[ 2.          2.23606798]
 [ 0.14142136  0.90553851]] [[ 0  6]
 [13 12]]
```

or, be more specific

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[ 2.          2.23606798]
 [ 0.14142136  0.90553851]] [[ 0  6]
 [13 12]]
```

`cKDTree.query_ball_point` (*self*, *x*, *r*, *p=2.*, *eps=0*)

Find all points within distance *r* of point(s) *x*.

**Parameters** **x** : array\_like, shape tuple + (self.m.)

The point or points to search for neighbors of.

**r** : positive float

The radius of points to return.

**p** : float, optional

Which Minkowski *p*-norm to use. Should be in the range [1, inf].

**eps** : nonnegative float, optional

Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ .

**n\_jobs** : int, optional

Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.

**Returns** **results** : list or array of lists

If *x* is a single point, returns a list of the indices of the neighbors of *x*. If *x* is an array of points, returns an object array of shape tuple containing lists of neighbors.

### Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a `cKDTree` and using `query_ball_tree`.

### Examples

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:4, 0:4]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.cKDTree(points)
>>> tree.query_ball_point([2, 0], 1)
[4, 8, 9, 12]
```

`cKDTree.query_ball_tree` (*self*, *other*, *r*, *p=2.*, *eps=0*)

Find all pairs of points whose distance is at most *r*

**Parameters** **other** : cKDTree instance

The tree containing points to search against.

**r** : float

The maximum distance, has to be positive.

**p** : float, optional  
Which Minkowski norm to use.  $p$  has to meet the condition  $1 \leq p \leq \text{infinity}$ .

**eps** : float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ .  $\text{eps}$  has to be non-negative.

**Returns** **results** : list of lists  
For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

`cKDTree.query_pairs` (*self*, *r*, *p=2.*, *eps=0*)  
Find all pairs of points whose distance is at most *r*.

**Parameters** **r** : positive float  
The maximum distance.

**p** : float, optional  
Which Minkowski norm to use.  $p$  has to meet the condition  $1 \leq p \leq \text{infinity}$ .

**eps** : float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ .  $\text{eps}$  has to be non-negative.

**output\_type** : string, optional  
Choose the output container, 'set' or 'ndarray'. Default: 'set'

**Returns** **results** : set or ndarray  
Set of pairs  $(i, j)$ , with  $i < j$ , for which the corresponding positions are close. If `output_type` is 'ndarray', an ndarray is returned instead of a set.

`cKDTree.sparse_distance_matrix` (*self*, *other*, *max\_distance*, *p=2.*)  
Compute a sparse distance matrix

Computes a distance matrix between two `cKDTree`s, leaving as zero any distance greater than `max_distance`.

**Parameters** **other** : `cKDTree`  
**max\_distance** : positive float  
**p** : float,  $1 \leq p \leq \text{infinity}$   
Which Minkowski  $p$ -norm to use.

**output\_type** : string, optional  
Which container to use for output data. Options: 'dok\_matrix', 'coo\_matrix', 'dict' or 'ndarray'. Default: 'dok\_matrix'.

**Returns** **result** : `dok_matrix`, `coo_matrix`, `dict` or `ndarray`  
Sparse matrix representing the results in "dictionary of keys" format. If a dict is returned the keys are  $(i, j)$  tuples of indices. If `output_type` is 'ndarray' a record array with fields 'i', 'j', and 'k' is returned,

### Distance computations (*scipy.spatial.distance*)

#### Function Reference

Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.

<code>pdist(X[, metric])</code>	Pairwise distances between observations in n-dimensional space.
<code>cdist(XA, XB[, metric])</code>	Computes distance between each pair of the two collections of inputs.
<code>squareform(X[, force, checks])</code>	Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.
<code>directed_hausdorff(u, v[, seed])</code>	Computes the directed Hausdorff distance between two N-D arrays.

`scipy.spatial.distance.pdist` (*X*, *metric*='euclidean', \*args, \*\*kwargs)

Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

**Parameters**    **X** : ndarray

An m by n array of m original observations in an n-dimensional space.

**metric** : str or function, optional

The distance metric to use. The distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.

**\*args** : tuple. Deprecated.

Additional arguments should be passed as keyword arguments

**\*\*kwargs** : dict, optional

Extra arguments to *metric*: refer to each metric documentation for a list of all possible arguments.

Some possible arguments:

**p** : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.

**w** : ndarray The weight vector for metrics that support weights (e.g., Minkowski).

**V** : ndarray The variance vector for standardized Euclidean. Default: var(X, axis=0, ddof=1)

**VI** : ndarray The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(X.T)).T

**out** : ndarray. The output array If not None, condensed distance matrix Y is stored in this array. Note: metric independent, it will become a regular keyword arg in a future scipy version

**Returns**        **Y** : ndarray

Returns a condensed distance matrix Y. For each *i* and *j* (where  $i < j < m$ ), where *m* is the number of original observations. The metric `dist(u=X[i], v=X[j])` is computed and stored in entry `ij`.

**See also:**

**squareform** converts between condensed distance matrices and square distance matrices.

**Notes**

See `squareform` for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. `Y = pdist(X, 'euclidean')`

Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix  $X$ .

2. `Y = pdist(X, 'minkowski', p=2.)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  ( $p$ -norm) where  $p \geq 1$ .

3. `Y = pdist(X, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = pdist(X, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two  $n$ -vectors  $u$  and  $v$  is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}$$

$V$  is the variance vector;  $V[i]$  is the variance computed over all the  $i$ 'th components of the points. If not passed, it is automatically computed.

5. `Y = pdist(X, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6. `Y = pdist(X, 'cosine')`

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|* \|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7. `Y = pdist(X, 'correlation')`

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8. `Y = pdist(X, 'hamming')`

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9. `Y = pdist(X, 'jaccard')`

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree.

10. `Y = pdist(X, 'chebyshev')`

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|$$

11. `Y = pdist(X, 'canberra')`

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

12.Y = pdist(X, 'braycurtis')

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i + v_i|}$$

13.Y = pdist(X, 'mahalanobis', VI=None)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u-v)(1/V)(u-v)^T}$  where  $(1/V)$  (the VI variable) is the inverse covariance. If VI is not None, VI will be used as the inverse covariance matrix.

14.Y = pdist(X, 'yule')

Computes the Yule distance between each pair of boolean vectors. (see yule function documentation)

15.Y = pdist(X, 'matching')

Synonym for 'hamming'.

16.Y = pdist(X, 'dice')

Computes the Dice distance between each pair of boolean vectors. (see dice function documentation)

17.Y = pdist(X, 'kulsinski')

Computes the Kulsinski distance between each pair of boolean vectors. (see kulsinski function documentation)

18.Y = pdist(X, 'rogerstanimoto')

Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see rogerstanimoto function documentation)

19.Y = pdist(X, 'russellrao')

Computes the Russell-Rao distance between each pair of boolean vectors. (see russellrao function documentation)

20.Y = pdist(X, 'sokalmichener')

Computes the Sokal-Michener distance between each pair of boolean vectors. (see sokalmichener function documentation)

21.Y = pdist(X, 'sokalsneath')

Computes the Sokal-Sneath distance between each pair of boolean vectors. (see sokalsneath function documentation)

22.Y = pdist(X, 'wminkowski', p=2, w=w)

Computes the weighted Minkowski distance between each pair of vectors. (see wminkowski function documentation)

23.Y = pdist(X, f)

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = pdist(X, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = pdist(X, sokalsneath)
```

would calculate the pair-wise distances between the vectors in  $X$  using the Python function `sokalsneath`. This would result in `sokalsneath` being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax.:

```
dm = pdist(X, 'sokalsneath')
```

`scipy.spatial.distance.cdist` ( $XA, XB, metric='euclidean', *args, **kwargs$ )

Computes distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

**Parameters**    **XA** : ndarray

An  $m_A$  by  $n$  array of  $m_A$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.

**XB** : ndarray

An  $m_B$  by  $n$  array of  $m_B$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.

**metric** : str or callable, optional

The distance metric to use. If a string, the distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'wminkowski', 'yule'.

**\*args** : tuple. Deprecated.

Additional arguments should be passed as keyword arguments

**\*\*kwargs** : dict, optional

Extra arguments to *metric*: refer to each metric documentation for a list of all possible arguments.

Some possible arguments:

**p** : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.

**w** : ndarray The weight vector for metrics that support weights (e.g., Minkowski).

**V** : ndarray The variance vector for standardized Euclidean. Default: `var(vstack([XA, XB]), axis=0, ddof=1)`

**VI** : ndarray The inverse of the covariance matrix for Mahalanobis. Default: `inv(cov(vstack([XA, XB].T))).T`

**out** : ndarray The output array If not None, the distance matrix  $Y$  is stored in this array. Note: metric independent, it will become a regular keyword arg in a future scipy version

**Returns**        **Y** : ndarray

A  $m_A$  by  $m_B$  distance matrix is returned. For each  $i$  and  $j$ , the metric `dist(u=XA[i], v=XB[j])` is computed and stored in the  $ij$  th entry.

**Raises**        **ValueError**

An exception is thrown if  $XA$  and  $XB$  do not have the same number of columns.

### Notes

The following are common calling conventions:

1.Y = cdist(XA, XB, 'euclidean')

Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix X.

2.Y = cdist(XA, XB, 'minkowski', p=2.)

Computes the distances using the Minkowski distance  $\|u - v\|_p$  ( $p$ -norm) where  $p \geq 1$ .

3.Y = cdist(XA, XB, 'cityblock')

Computes the city block or Manhattan distance between the points.

4.Y = cdist(XA, XB, 'seuclidean', V=None)

Computes the standardized Euclidean distance. The standardized Euclidean distance between two  $n$ -vectors  $u$  and  $v$  is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}.$$

$V$  is the variance vector;  $V[i]$  is the variance computed over all the  $i$ 'th components of the points. If not passed, it is automatically computed.

5.Y = cdist(XA, XB, 'sqeuclidean')

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6.Y = cdist(XA, XB, 'cosine')

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|* \|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7.Y = cdist(XA, XB, 'correlation')

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8.Y = cdist(XA, XB, 'hamming')

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix X can be of type boolean.

9.Y = cdist(XA, XB, 'jaccard')

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree where at least one of them is non-zero.

10.Y = cdist(XA, XB, 'chebyshev')

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|.$$

11.Y = cdist(XA, XB, 'canberra')

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

```
12.Y = cdist(XA, XB, 'braycurtis')
```

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}$$

```
13.Y = cdist(XA, XB, 'mahalanobis', VI=None)
```

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u-v)(1/V)(u-v)^T}$  where  $(1/V)$  (the `VI` variable) is the inverse covariance. If `VI` is not `None`, `VI` will be used as the inverse covariance matrix.

```
14.Y = cdist(XA, XB, 'yule')
```

Computes the Yule distance between the boolean vectors. (see `yule` function documentation)

```
15.Y = cdist(XA, XB, 'matching')
```

Synonym for ‘hamming’.

```
16.Y = cdist(XA, XB, 'dice')
```

Computes the Dice distance between the boolean vectors. (see `dice` function documentation)

```
17.Y = cdist(XA, XB, 'kulsinski')
```

Computes the Kulsinski distance between the boolean vectors. (see `kulsinski` function documentation)

```
18.Y = cdist(XA, XB, 'rogerstanimoto')
```

Computes the Rogers-Tanimoto distance between the boolean vectors. (see `rogerstanimoto` function documentation)

```
19.Y = cdist(XA, XB, 'russellrao')
```

Computes the Russell-Rao distance between the boolean vectors. (see `russellrao` function documentation)

```
20.Y = cdist(XA, XB, 'sokalmichener')
```

Computes the Sokal-Michener distance between the boolean vectors. (see `sokalmichener` function documentation)

```
21.Y = cdist(XA, XB, 'sokalsneath')
```

Computes the Sokal-Sneath distance between the vectors. (see `sokalsneath` function documentation)

```
22.Y = cdist(XA, XB, 'wminkowski', p=2., w=w)
```

Computes the weighted Minkowski distance between the vectors. (see `wminkowski` function documentation)

```
23.Y = cdist(XA, XB, f)
```

Computes the distance between all pairs of vectors in `X` using the user supplied 2-arity function `f`. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = cdist(XA, XB, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = cdist(XA, XB, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function *sokalsneath*. This would result in *sokalsneath* being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

```
dm = cdist(XA, XB, 'sokalsneath')
```

### Examples

Find the Euclidean distances between four 2-D coordinates:

```
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672),
...           (35.1174, -89.9711),
...           (35.9728, -83.9422),
...           (36.1667, -86.7833)]
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0.         ,  4.7044,  1.6172,  1.8856],
       [ 4.7044,  0.         ,  6.0893,  3.3561],
       [ 1.6172,  6.0893,  0.         ,  2.8477],
       [ 1.8856,  3.3561,  2.8477,  0.         ]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```
>>> a = np.array([[0, 0, 0],
...               [0, 0, 1],
...               [0, 1, 0],
...               [0, 1, 1],
...               [1, 0, 0],
...               [1, 0, 1],
...               [1, 1, 0],
...               [1, 1, 1]])
>>> b = np.array([[0.1, 0.2, 0.4]])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
       [ 0.9],
       [ 1.3],
       [ 1.5],
       [ 1.5],
       [ 1.7],
       [ 2.1],
       [ 2.3]])
```

`scipy.spatial.distance.squareform(X, force='no', checks=True)`

Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.

**Parameters** **X** : ndarray

Either a condensed or redundant distance matrix.

**force** : str, optional

As with MATLAB(TM), if *force* is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.

**checks** : bool, optional

If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that  $X - X.T$  is small and  $\text{diag}(X)$  is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

**Returns** **Y** : ndarray

If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

### Notes

1.  $v = \text{squareform}(X)$

Given a square  $d$ -by- $d$  symmetric distance matrix  $X$ ,  $v = \text{squareform}(X)$  returns a  $d * (d-1) / 2$  (or  $\binom{n}{2}$ ) sized vector  $v$ .

$v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  is the distance between points  $i$  and  $j$ . If  $X$  is non-square or asymmetric, an error is returned.

2.  $X = \text{squareform}(v)$

Given a  $d * (d-1) / 2$  sized  $v$  for some integer  $d \geq 2$  encoding distances as described,  $X = \text{squareform}(v)$  returns a  $d$  by  $d$  distance matrix  $X$ . The  $X[i, j]$  and  $X[j, i]$  values are set to  $v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  and all diagonal elements are zero.

In SciPy 0.19.0, `squareform` stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

`scipy.spatial.distance.directed_hausdorff(u, v, seed=0)`

Computes the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

**Parameters** **u** : (M,N) ndarray

Input array.

**v** : (O,N) ndarray

Input array.

**seed** : int or None

Local `np.random.RandomState` seed. Default is 0, a random shuffling of  $u$  and  $v$  that guarantees reproducibility.

**Returns** **d** : double

The directed Hausdorff distance between arrays  $u$  and  $v$ ,

**index\_1** : int

index of point contributing to Hausdorff pair in  $u$

**index\_2** : int

index of point contributing to Hausdorff pair in  $v$

**See also:**

`scipy.spatial.procrustes`

Another similarity test for two data sets

### Notes

Uses the early break technique and the random sampling approach described by [R44]. Although worst-case performance is  $O(m * o)$  (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is  $O(m)$ , which is satisfied by selecting an inner loop distance

that is less than `cmax` and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to  $O(m)$ .

New in version 0.19.0.

### References

[R44]

### Examples

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
...              (0.0, 1.0),
...              (-1.0, 0.0),
...              (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
...              (0.0, 2.0),
...              (-2.0, 0.0),
...              (0.0, -4.0)])
```

```
>>> directed_hausdorff(u, v)[0]
2.23606797749979
>>> directed_hausdorff(v, u)[0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```
>>> max(directed_hausdorff(u, v)[0], directed_hausdorff(v, u)[0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```
>>> directed_hausdorff(v, u)[1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

<code>is_valid_dm(D[, tol, throw, name, warning])</code>	Returns True if input array is a valid distance matrix.
<code>is_valid_y(y[, warning, throw, name])</code>	Returns True if the input array is a valid condensed distance matrix.
<code>num_obs_dm(d)</code>	Returns the number of original observations that correspond to a square, redundant distance matrix.
<code>num_obs_y(Y)</code>	Returns the number of original observations that correspond to a condensed distance matrix.

`scipy.spatial.distance.is_valid_dm(D, tol=0.0, throw=False, name='D', warning=False)`

Returns True if input array is a valid distance matrix.

Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.

**Parameters** **D**: ndarray

The candidate object to test for validity.

**tol** : float, optional  
The distance matrix should be symmetric. *tol* is the maximum difference between entries  $i_j$  and  $j_i$  for the distance metric to be considered symmetric.

**throw** : bool, optional  
An exception is thrown if the distance matrix passed is not valid.

**name** : str, optional  
The name of the variable to checked. This is useful if *throw* is set to True so the offending variable can be identified in the exception message when an exception is thrown.

**warning** : bool, optional  
Instead of throwing an exception, a warning message is raised.

**Returns** **valid** : bool  
True if the variable *D* passed is a valid distance matrix.

**Notes**

Small numerical differences in *D* and *D.T* and non-zerosness of the diagonal are ignored if they are within the tolerance specified by *tol*.

`scipy.spatial.distance.is_valid_y` (*y*, *warning=False*, *throw=False*, *name=None*)

Returns True if the input array is a valid condensed distance matrix.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient  $\binom{n}{2}$  for some positive integer *n*.

**Parameters** **y** : ndarray  
The condensed distance matrix.

**warning** : bool, optional  
Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. *name* is used when referencing the offending variable.

**throw** : bool, optional  
Throws an exception if the variable passed is not a valid condensed distance matrix.

**name** : bool, optional  
Used when referencing the offending variable in the warning or exception message.

`scipy.spatial.distance.num_obs_dm` (*d*)

Returns the number of original observations that correspond to a square, redundant distance matrix.

**Parameters** **d** : ndarray  
The target distance matrix.

**Returns** **num\_obs\_dm** : int  
The number of observations in the redundant distance matrix.

`scipy.spatial.distance.num_obs_y` (*Y*)

Returns the number of original observations that correspond to a condensed distance matrix.

**Parameters** **Y** : ndarray  
Condensed distance matrix.

**Returns** **n** : int  
The number of observations in the condensed distance matrix *Y*.

Distance functions between two numeric vectors *u* and *v*. Computing distances over a large collection of vectors is inefficient for these functions. Use `pdist` for this purpose.

Continued on next page

Table 5.225 – continued from previous page

<code>braycurtis(u, v[, w])</code>	Computes the Bray-Curtis distance between two 1-D arrays.
<code>canberra(u, v[, w])</code>	Computes the Canberra distance between two 1-D arrays.
<code>chebyshev(u, v)</code>	Computes the Chebyshev distance.
<code>cityblock(u, v[, w])</code>	Computes the City Block (Manhattan) distance.
<code>correlation(u, v[, w, centered])</code>	Computes the correlation distance between two 1-D arrays.
<code>cosine(u, v[, w])</code>	Computes the Cosine distance between 1-D arrays.
<code>euclidean(u, v[, w])</code>	Computes the Euclidean distance between two 1-D arrays.
<code>mahalanobis(u, v, VI)</code>	Computes the Mahalanobis distance between two 1-D arrays.
<code>minkowski(u, v[, p, w])</code>	Computes the Minkowski distance between two 1-D arrays.
<code>seuclidean(u, v, V)</code>	Returns the standardized Euclidean distance between two 1-D arrays.
<code>squeuclidean(u, v[, w])</code>	Computes the squared Euclidean distance between two 1-D arrays.
<code>wminkowski(u, v, p, w)</code>	Computes the weighted Minkowski distance between two 1-D arrays.

`scipy.spatial.distance.braycurtis(u, v, w=None)`

Computes the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

$$\sum |u_i - v_i| / \sum |u_i + v_i|$$

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- w** : (N,) array\_like, optional  
The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- braycurtis** : double  
The Bray-Curtis distance between 1-D arrays *u* and *v*.

`scipy.spatial.distance.canberra(u, v, w=None)`

Computes the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- w** : (N,) array\_like, optional  
The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- canberra** : double  
The Canberra distance between vectors *u* and *v*.

**Notes**

When  $u[i]$  and  $v[i]$  are 0 for given  $i$ , then the fraction  $0/0 = 0$  is used in the calculation.

`scipy.spatial.distance.chebyshev` ( $u, v$ )

Computes the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays  $u$  and  $v$ , which is defined as

$$\max_i |u_i - v_i|.$$

**Parameters** **u** : (N,) array\_like  
Input vector.

**v** : (N,) array\_like

**Returns** **chebyshev** : double  
Input vector.

The Chebyshev distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.cityblock` ( $u, v, w=None$ )

Computes the City Block (Manhattan) distance.

Computes the Manhattan distance between two 1-D arrays  $u$  and  $v$ , which is defined as

$$\sum_i |u_i - v_i|.$$

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like

Input array.

**w** : (N,) array\_like, optional

The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **cityblock** : double

The City Block (Manhattan) distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.correlation` ( $u, v, w=None, centered=True$ )

Computes the correlation distance between two 1-D arrays. The correlation distance between  $u$  and  $v$ , is defined as

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|u - \bar{u}\|_2 \|v - \bar{v}\|_2}$$

where  $\bar{u}$  is the mean of the elements of  $u$  and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like

Input array.

**w** : (N,) array\_like, optional

The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **correlation** : double

The correlation distance between 1-D array  $u$  and  $v$ .

`scipy.spatial.distance.cosine` ( $u, v, w=None$ )

Computes the Cosine distance between 1-D arrays. The Cosine distance between  $u$  and  $v$ , is defined as

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}.$$

where  $u \cdot v$  is the dot product of  $u$  and  $v$ .

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- w** : (N,) array\_like, optional  
The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- cosine** : double  
The Cosine distance between vectors *u* and *v*.

`scipy.spatial.distance.euclidean` (*u*, *v*, *w=None*)

Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays *u* and *v*, is defined as

$$\|u - v\|_2 = \left( \sum (w_i |u_i - v_i|^2) \right)^{1/2}$$

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- w** : (N,) array\_like, optional  
The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- euclidean** : double  
The Euclidean distance between vectors *u* and *v*.

`scipy.spatial.distance.mahalanobis` (*u*, *v*, *VI*)

Computes the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays *u* and *v*, is defined as

$$\sqrt{(u - v)V^{-1}(u - v)^T}$$

where *V* is the covariance matrix. Note that the argument *VI* is the inverse of *V*.

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- VI** : ndarray  
The inverse of the covariance matrix.

**Returns**

- mahalanobis** : double  
The Mahalanobis distance between vectors *u* and *v*.

`scipy.spatial.distance.minkowski` (*u*, *v*, *p=2*, *w=None*)

Computes the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays *u* and *v*, is defined as

$$\|u - v\|_p = \left( \sum |u_i - v_i|^p \right)^{1/p} = \left( \sum w_i (|u_i - v_i|^p) \right)^{1/p}$$

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.

**p** : int  
The order of the norm of the difference  $\|u - v\|_p$ .

**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **minkowski** : double  
The Minkowski distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.seuclidean(u, v, V)`  
Returns the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between  $u$  and  $v$ .

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like  
Input array.

**V** : (N,) array\_like  
 $V$  is an 1-D array of component variances. It is usually computed among a larger collection vectors.

**Returns** **seuclidean** : double  
The standardized Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sqeuclidean(u, v, w=None)`  
Computes the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between  $u$  and  $v$  is defined as

$$\|u - v\|_2^2$$

$$\left( \sum (w_i |u_i - v_i|^2) \right)$$

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like  
Input array.

**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **sqeuclidean** : double  
The squared Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.wminkowski(u, v, p, w)`  
Computes the weighted Minkowski distance between two 1-D arrays. The weighted Minkowski distance between  $u$  and  $v$ , defined as

$$\left( \sum (|w_i(u_i - v_i)|^p) \right)^{1/p} .$$

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like  
Input array.

**p** : int  
The order of the norm of the difference  $\|u - v\|_p$ .

**w** : (N,) array\_like  
The weight vector.

**Returns** **wminkowski** : double  
The weighted Minkowski distance between vectors  $u$  and  $v$ .

**Notes**

`wminkowski` is DEPRECATED. It implements a definition where weights are powered. It is recommended to use the weighted version of `minkowski` instead. This function will be removed in a future version of `scipy`.

Distance functions between two boolean vectors (representing sets)  $u$  and  $v$ . As in the case of numerical vectors, `pdist` is more efficient for computing the distances between all pairs.

<code>dice(u, v[, w])</code>	Computes the Dice dissimilarity between two boolean 1-D arrays.
<code>hamming(u, v[, w])</code>	Computes the Hamming distance between two 1-D arrays.
<code>jaccard(u, v[, w])</code>	Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.
<code>kulsinski(u, v[, w])</code>	Computes the Kulsinski dissimilarity between two boolean 1-D arrays.
<code>rogerstanimoto(u, v[, w])</code>	Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.
<code>russellrao(u, v[, w])</code>	Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.
<code>sokalmichener(u, v[, w])</code>	Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.
<code>sokalsneath(u, v[, w])</code>	Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.
<code>yule(u, v[, w])</code>	Computes the Yule dissimilarity between two boolean 1-D arrays.

`scipy.spatial.distance.dice(u, v, w=None)`

Computes the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between  $u$  and  $v$ , is

$$\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

- u** : (N,) ndarray, bool  
Input 1-D array.
- v** : (N,) ndarray, bool  
Input 1-D array.
- w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is `None`, which gives each value a weight of 1.0

**Returns**

- dice** : double  
The Dice dissimilarity between 1-D arrays  $u$  and  $v$ .

`scipy.spatial.distance.hamming(u, v, w=None)`

Computes the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays  $u$  and  $v$ , is simply the proportion of disagreeing components in  $u$  and  $v$ . If  $u$  and  $v$  are boolean vectors, the Hamming distance is

$$\frac{c_{01} + c_{10}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

- u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like  
Input array.

**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **hamming** : double  
The Hamming distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.jaccard` ( $u, v, w=None$ )

Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays  $u$  and  $v$ , is defined as

$$\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
Input array.

**v** : (N,) array\_like, bool  
Input array.

**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **jaccard** : double  
The Jaccard distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.kulsinski` ( $u, v, w=None$ )

Computes the Kulsinski dissimilarity between two boolean 1-D arrays.

The Kulsinski dissimilarity between two boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
Input array.

**v** : (N,) array\_like, bool  
Input array.

**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **kulsinski** : double  
The Kulsinski distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.rogerstanimoto` ( $u, v, w=None$ )

Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{R}{c_{TT} + c_{FF} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters** **u** : (N,) array\_like, bool  
Input array.

**v** : (N,) array\_like, bool  
Input array.

**Parameters** **w** : (N,) array\_like, optional  
 The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns** **rogerstanimoto** : double  
 The Rogers-Tanimoto dissimilarity between vectors *u* and *v*.

`scipy.spatial.distance.russellrao` (*u*, *v*, *w=None*)  
 Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays, *u* and *v*, is defined as

$$\frac{n - c_{TT}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.

**v** : (N,) array\_like, bool  
 Input array.

**w** : (N,) array\_like, optional  
 The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns** **russellrao** : double  
 The Russell-Rao dissimilarity between vectors *u* and *v*.

`scipy.spatial.distance.sokalmichener` (*u*, *v*, *w=None*)  
 Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays *u* and *v*, is defined as

$$\frac{R}{S + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ ,  $R = 2 * (c_{TF} + c_{FT})$  and  $S = c_{FF} + c_{TT}$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.

**v** : (N,) array\_like, bool  
 Input array.

**w** : (N,) array\_like, optional  
 The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns** **sokalmichener** : double  
 The Sokal-Michener dissimilarity between vectors *u* and *v*.

`scipy.spatial.distance.sokalsneath` (*u*, *v*, *w=None*)  
 Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between *u* and *v*,

$$\frac{R}{c_{TT} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.

**v** : (N,) array\_like, bool  
 Input array.

**w** : (N,) array\_like, optional

**Returns** `sokalsneath` : double  
 The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0  
 The Sokal-Sneath dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.yule` ( $u, v, w=None$ )  
 Computes the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

$$\frac{R}{c_{TT} * c_{FF} + \frac{R}{2}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2.0 * c_{TF} * c_{FT}$ .

**Parameters** `u` : (N,) array\_like, bool  
 Input array.  
`v` : (N,) array\_like, bool  
 Input array.  
`w` : (N,) array\_like, optional  
 The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0  
**Returns** `yule` : double  
 The Yule dissimilarity between vectors  $u$  and  $v$ .

`hamming` also operates over discrete numerical vectors.

**Functions**

<code>braycurtis(u, v[, w])</code>	Computes the Bray-Curtis distance between two 1-D arrays.
<code>callable(object) -&gt; bool</code>	Return whether the object is callable (i.e., some kind of function).
<code>canberra(u, v[, w])</code>	Computes the Canberra distance between two 1-D arrays.
<code>cdist(XA, XB[, metric])</code>	Computes distance between each pair of the two collections of inputs.
<code>chebyshev(u, v)</code>	Computes the Chebyshev distance.
<code>cityblock(u, v[, w])</code>	Computes the City Block (Manhattan) distance.
<code>correlation(u, v[, w, centered])</code>	Computes the correlation distance between two 1-D arrays.
<code>cosine(u, v[, w])</code>	Computes the Cosine distance between 1-D arrays.
<code>dice(u, v[, w])</code>	Computes the Dice dissimilarity between two boolean 1-D arrays.
<code>directed_hausdorff(u, v[, seed])</code>	Computes the directed Hausdorff distance between two N-D arrays.
<code>euclidean(u, v[, w])</code>	Computes the Euclidean distance between two 1-D arrays.
<code>hamming(u, v[, w])</code>	Computes the Hamming distance between two 1-D arrays.
<code>is_valid_dm(D[, tol, throw, name, warning])</code>	Returns True if input array is a valid distance matrix.
<code>is_valid_y(y[, warning, throw, name])</code>	Returns True if the input array is a valid condensed distance matrix.
<code>jaccard(u, v[, w])</code>	Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.
<code>kulsinski(u, v[, w])</code>	Computes the Kulsinski dissimilarity between two boolean 1-D arrays.
<code>mahalanobis(u, v, VI)</code>	Computes the Mahalanobis distance between two 1-D arrays.
<code>matching(*args, **kwargs)</code>	<code>matching</code> is deprecated!

Continued on next page

Table 5.227 – continued from previous page

<code>minkowski(u, v[, p, w])</code>	Computes the Minkowski distance between two 1-D arrays.
<code>namedtuple(typename, field_names[, verbose, ...])</code>	Returns a new subclass of tuple with named fields.
<code>norm(a[, ord, axis, keepdims])</code>	Matrix or vector norm.
<code>num_obs_dm(d)</code>	Returns the number of original observations that correspond to a square, redundant distance matrix.
<code>num_obs_y(Y)</code>	Returns the number of original observations that correspond to a condensed distance matrix.
<code>pdist(X[, metric])</code>	Pairwise distances between observations in n-dimensional space.
<code>rogerstanimoto(u, v[, w])</code>	Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.
<code>russellrao(u, v[, w])</code>	Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.
<code>seuclidean(u, v, V)</code>	Returns the standardized Euclidean distance between two 1-D arrays.
<code>sokalmichener(u, v[, w])</code>	Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.
<code>sokalsneath(u, v[, w])</code>	Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.
<code>squeuclidean(u, v[, w])</code>	Computes the squared Euclidean distance between two 1-D arrays.
<code>squareform(X[, force, checks])</code>	Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.
<code>wminkowski(u, v, p, w)</code>	Computes the weighted Minkowski distance between two 1-D arrays.
<code>yule(u, v[, w])</code>	Computes the Yule dissimilarity between two boolean 1-D arrays.

**Classes**

MetricInfo

**Attributes**

<code>partial</code>	<code>partial(func, *args, **keywords)</code> - new function with partial application
<code>xrange</code>	<code>xrange(start, stop[, step])</code> -> xrange object

**class** `scipy.spatial.Rectangle` (*maxes, mins*)  
 Hyperrectangle class.  
 Represents a Cartesian product of intervals.

**Methods**

<code>max_distance_point(x[, p])</code>	Return the maximum distance between input and points in the hyperrectangle.
<code>max_distance_rectangle(other[, p])</code>	Compute the maximum distance between points in the two hyperrectangles.
<code>min_distance_point(x[, p])</code>	Return the minimum distance between input and points in the hyperrectangle.

Continued on next page

Table 5.229 – continued from previous page

<code>min_distance_rectangle(other[, p])</code>	Compute the minimum distance between points in the two hyperrectangles.
<code>split(d, split)</code>	Produce two hyperrectangles by splitting.
<code>volume()</code>	Total volume.

`Rectangle.max_distance_point` ( $x, p=2.0$ )

Return the maximum distance between input and points in the hyperrectangle.

**Parameters**

- x** : array\_like  
Input array.
- p** : float, optional  
Input.

`Rectangle.max_distance_rectangle` ( $other, p=2.0$ )

Compute the maximum distance between points in the two hyperrectangles.

**Parameters**

- other** : hyperrectangle  
Input.
- p** : float, optional  
Input.

`Rectangle.min_distance_point` ( $x, p=2.0$ )

Return the minimum distance between input and points in the hyperrectangle.

**Parameters**

- x** : array\_like  
Input.
- p** : float, optional  
Input.

`Rectangle.min_distance_rectangle` ( $other, p=2.0$ )

Compute the minimum distance between points in the two hyperrectangles.

**Parameters**

- other** : hyperrectangle  
Input.
- p** : float  
Input.

`Rectangle.split` ( $d, split$ )

Produce two hyperrectangles by splitting.

In general, if you need to compute maximum and minimum distances to the children, it can be done more efficiently by updating the maximum and minimum distances to the parent.

**Parameters**

- d** : int  
Axis to split hyperrectangle along.
- split** : float  
Position along axis  $d$  to split at.

`Rectangle.volume` ()

Total volume.

## 5.24.2 Delaunay Triangulation, Convex Hulls and Voronoi Diagrams

<code>Delaunay(points[, furthest_site, ...])</code>	Delaunay tessellation in N dimensions.
<code>ConvexHull(points[, incremental, qhull_options])</code>	Convex hulls in N dimensions.

Continued on next page

Table 5.230 – continued from previous page

<code>Voronoi(points[, furthest_site, ...])</code>	Voronoi diagrams in N dimensions.
<code>SphericalVoronoi(points[, radius, center, ...])</code>	Voronoi diagrams on the surface of a sphere.
<code>HalfspaceIntersection(halfspaces, interior_point)</code>	Halfspace intersections in N dimensions.

**class** `scipy.spatial.Delaunay` (*points, furthest\_site=False, incremental=False, qhull\_options=None*)  
 Delaunay tessellation in N dimensions.

New in version 0.9.

**Parameters**

- points** : ndarray of floats, shape (npoints, ndim)  
 Coordinates of points to triangulate
- furthest\_site** : bool, optional  
 Whether to compute a furthest-site Delaunay triangulation. Default: False  
 New in version 0.12.0.
- incremental** : bool, optional  
 Allow adding new points incrementally. This takes up some additional resources.
- qhull\_options** : str, optional  
 Additional options to pass to Qhull. See Qhull manual for details. Option “Qt” is always enabled. Default: “Qbb Qc Qz Qx Q12” for ndim > 4 and “Qbb Qc Qz Q12” otherwise. Incremental mode omits “Qz”.  
 New in version 0.12.0.

**Raises**

- QhullError**  
 Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
- ValueError**  
 Raised if an incompatible array is given as input.

**Notes**

The tessellation is computed using the Qhull library [Qhull library](#).

---

**Note:** Unless you pass in the Qhull option “QJ”, Qhull does not guarantee that each input point appears as a vertex in the Delaunay triangulation. Omitted points are listed in the *coplanar* attribute.

---

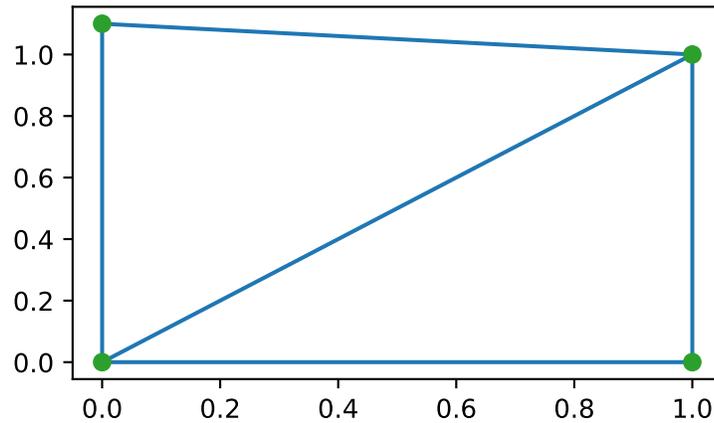

**Examples**

Triangulation of a set of points:

```
>>> points = np.array([[0, 0], [0, 1.1], [1, 0], [1, 1]])
>>> from scipy.spatial import Delaunay
>>> tri = Delaunay(points)
```

We can plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices.copy())
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> plt.show()
```

Point indices and coordinates for the two triangles forming the triangulation:

```
>>> tri.simplices
array([[2, 3, 0],           # may vary
       [3, 1, 0]], dtype=int32)
```

Note that depending on how rounding errors go, the simplices may be in a different order than above.

```
>>> points[tri.simplices]
array([[ 1. ,  0. ],           # may vary
       [ 1. ,  1. ],
       [ 0. ,  0. ]],
      [[ 1. ,  1. ],
       [ 0. ,  1.1],
       [ 0. ,  0. ]])
```

Triangle 0 is the only neighbor of triangle 1, and it's opposite to vertex 1 of triangle 1:

```
>>> tri.neighbors[1]
array([-1,  0, -1], dtype=int32)
>>> points[tri.simplices[1,1]]
array([ 0. ,  1.1])
```

We can find out which triangle points are in:

```
>>> p = np.array([(0.1, 0.2), (1.5, 0.5), (0.5, 1.05)])
>>> tri.find_simplex(p)
array([ 1, -1,  1], dtype=int32)
```

The returned integers in the array are the indices of the simplex the corresponding point is in. If -1 is returned, the point is in no simplex. Be aware that the shortcut in the following example only works correctly for valid points as invalid points result in -1 which is itself a valid index for the last simplex in the list.

```
>>> p_valids = np.array([(0.1, 0.2), (0.5, 1.05)])
>>> tri.simplices[tri.find_simplex(p_valids)]
array([[3, 1, 0],           # may vary
       [3, 1, 0]], dtype=int32)
```

We can also compute barycentric coordinates in triangle 1 for these points:

```
>>> b = tri.transform[1,:2].dot(np.transpose(p - tri.transform[1,2]))
>>> np.c_[np.transpose(b), 1 - b.sum(axis=0)]
array([[ 0.1      ,  0.09090909,  0.80909091],
       [ 1.5      , -0.90909091,  0.40909091],
       [ 0.5      ,  0.5       ,  0.          ]])
```

The coordinates for the first point are all positive, meaning it is indeed inside the triangle. The third point is on a vertex, hence its null third coordinate.

**Attributes**

<code>transform</code>	Affine transform from $x$ to the barycentric coordinates $c$ .
<code>vertex_to_simplex</code>	Lookup array, from a vertex, to some simplex which it is a part of.
<code>convex_hull</code>	Vertices of facets forming the convex hull of the point set.
<code>vertex_neighbor_vertices</code>	Neighboring vertices of vertices.

**Delaunay.transform**

Affine transform from  $x$  to the barycentric coordinates  $c$ .

**Type** ndarray of double, shape (nsimplex, ndim+1, ndim)

This is defined by:

$$T c = x - r$$

At vertex  $j$ ,  $c_j = 1$  and the other coordinates zero.

For simplex  $i$ , `transform[i,:ndim,:ndim]` contains inverse of the matrix  $T$ , and `transform[i,ndim,:]` contains the vector  $r$ .

**Delaunay.vertex\_to\_simplex**

Lookup array, from a vertex, to some simplex which it is a part of.

**Type** ndarray of int, shape (npoints,)

**Delaunay.convex\_hull**

Vertices of facets forming the convex hull of the point set.

**Type** ndarray of int, shape (nfaces, ndim)

The array contains the indices of the points belonging to the (N-1)-dimensional facets that form the convex hull of the triangulation.

---

**Note:** Computing convex hulls via the Delaunay triangulation is inefficient and subject to increased numerical instability. Use `ConvexHull` instead.

---

**Delaunay.vertex\_neighbor\_vertices**

Neighboring vertices of vertices.

Tuple of two ndarrays of int: (indptr, indices). The indices of neighboring vertices of vertex  $k$  are `indices[indptr[k]:indptr[k+1]]`.

points	(ndarray of double, shape (npoints, ndim)) Coordinates of input points.
simplices	(ndarray of ints, shape (nsimplex, ndim+1)) Indices of the points forming the simplices in the triangulation. For 2-D, the points are oriented counterclockwise.
neighbors	(ndarray of ints, shape (nsimplex, ndim+1)) Indices of neighbor simplices for each simplex. The kth neighbor is opposite to the kth vertex. For simplices at the boundary, -1 denotes no neighbor.
equations	(ndarray of double, shape (nsimplex, ndim+2)) [normal, offset] forming the hyperplane equation of the facet on the paraboloid (see <a href="#">Qhull documentation</a> for more).
paraboloid_scale, paraboloid_shift	(float) Scale and shift for the extra paraboloid dimension (see <a href="#">Qhull documentation</a> for more).
coplanar	(ndarray of int, shape (ncoplanar, 3)) Indices of coplanar points and the corresponding indices of the nearest facet and the nearest vertex. Coplanar points are input points which were <i>not</i> included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed. .. versionadded:: 0.12.0
vertices	Same as <i>simplices</i> , but deprecated.

**Methods**

<code>add_points(points[, restart])</code>	Process a set of additional new points.
<code>close()</code>	Finish incremental processing.
<code>find_simplex(self, xi[, bruteforce, tol])</code>	Find the simplices containing the given points.
<code>lift_points(self, x)</code>	Lift points to the Qhull paraboloid.
<code>plane_distance(self, xi)</code>	Compute hyperplane distances to the point <i>xi</i> from all simplices.

`Delaunay.add_points (points, restart=False)`

Process a set of additional new points.

**Parameters**    **points** : ndarray

New points to add. The dimensionality should match that of the initial points.

**restart** : bool, optional

Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**        **QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

`close`

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

`Delaunay.close ()`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

`Delaunay.find_simplex (self, xi, bruteforce=False, tol=None)`

Find the simplices containing the given points.

**Parameters**    **tri** : DelaunayInfo

Delaunay triangulation  
**xi** : ndarray of double, shape (..., ndim)  
 Points to locate  
**bruteforce** : bool, optional  
 Whether to only perform a brute-force search  
**tol** : float, optional  
 Tolerance allowed in the inside-triangle check. Default is  $100 * \text{eps}$ .  
**Returns** **i** : ndarray of int, same shape as *xi*  
 Indices of simplices containing each point. Points outside the triangulation get the value -1.

**Notes**

This uses an algorithm adapted from Qhull's `qh_findbestfacet`, which makes use of the connection between a convex hull and a Delaunay triangulation. After finding the simplex closest to the point in  $N+1$  dimensions, the algorithm falls back to directed search in  $N$  dimensions.

`Delaunay.lift_points` (*self*, *x*)  
 Lift points to the Qhull paraboloid.

`Delaunay.plane_distance` (*self*, *xi*)  
 Compute hyperplane distances to the point *xi* from all simplices.

**class** `scipy.spatial.ConvexHull` (*points*, *incremental=False*, *qhull\_options=None*)  
 Convex hulls in  $N$  dimensions.

New in version 0.12.0.

**Parameters** **points** : ndarray of floats, shape (npoints, ndim)  
 Coordinates of points to construct a convex hull from  
**incremental** : bool, optional  
 Allow adding new points incrementally. This takes up some additional resources.  
**qhull\_options** : str, optional  
 Additional options to pass to Qhull. See Qhull manual for details. (Default: "Qx" for  $\text{ndim} > 4$  and "" otherwise) Option "Qt" is always enabled.  
**Raises** **QhullError**  
 Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.  
**ValueError**  
 Raised if an incompatible array is given as input.

**Notes**

The convex hull is computed using the [Qhull library](#).

**References**

[[Qhull](#)]

**Examples**

Convex hull of a random set of points:

```

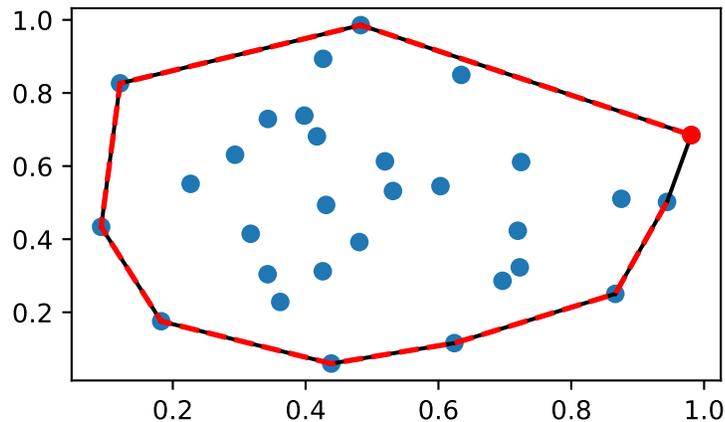

>>> from scipy.spatial import ConvexHull
>>> points = np.random.rand(30, 2) # 30 random points in 2-D
>>> hull = ConvexHull(points)
    
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> for simplex in hull.simplices:
...     plt.plot(points[simplex, 0], points[simplex, 1], 'k-')
```

We could also have directly used the vertices of the hull, which for 2-D are guaranteed to be in counterclockwise order:

```
>>> plt.plot(points[hull.vertices,0], points[hull.vertices,1], 'r--', lw=2)
>>> plt.plot(points[hull.vertices[0],0], points[hull.vertices[0],1], 'ro')
>>> plt.show()
```

### Attributes

points	(ndarray of double, shape (npoints, ndim)) Coordinates of input points.
vertices	(ndarray of ints, shape (nvertices,)) Indices of points forming the vertices of the convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.
simplices	(ndarray of ints, shape (nfacet, ndim)) Indices of points forming the simplicial facets of the convex hull.
neighbors	(ndarray of ints, shape (nfacet, ndim)) Indices of neighbor facets for each facet. The kth neighbor is opposite to the kth vertex. -1 denotes no neighbor.
equations	(ndarray of double, shape (nfacet, ndim+1)) [normal, offset] forming the hyperplane equation of the facet (see <a href="#">Qhull documentation</a> for more).
coplanar	(ndarray of int, shape (ncoplanar, 3)) Indices of coplanar points and the corresponding indices of the nearest facets and nearest vertex indices. Coplanar points are input points which were <i>not</i> included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed.
area	(float) Area of the convex hull
volume	(float) Volume of the convex hull

### Methods

<code>add_points(points[, restart])</code>	Process a set of additional new points.
<code>close()</code>	Finish incremental processing.

`ConvexHull.add_points` (*points*, *restart=False*)

Process a set of additional new points.

<b>Parameters</b>	<b>points</b> : ndarray	New points to add. The dimensionality should match that of the initial points.
	<b>restart</b> : bool, optional	Whether to restart processing from scratch, rather than adding points incrementally.
<b>Raises</b>	<b>QhullError</b>	Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

`close`

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

`ConvexHull.close` ()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**class** `scipy.spatial.Voronoi` (*points*, *furthest\_site=False*, *incremental=False*, *qhull\_options=None*)

Voronoi diagrams in N dimensions.

New in version 0.12.0.

<b>Parameters</b>	<b>points</b> : ndarray of floats, shape (npoints, ndim)	Coordinates of points to construct a convex hull from
	<b>furthest_site</b> : bool, optional	Whether to compute a furthest-site Voronoi diagram. Default: False
	<b>incremental</b> : bool, optional	Allow adding new points incrementally. This takes up some additional resources.
	<b>qhull_options</b> : str, optional	Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qbb Qc Qz Qx” for ndim > 4 and “Qbb Qc Qz” otherwise. Incremental mode omits “Qz”.)
<b>Raises</b>	<b>QhullError</b>	Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
	<b>ValueError</b>	Raised if an incompatible array is given as input.

**Notes**

The Voronoi diagram is computed using the [Qhull library](#).

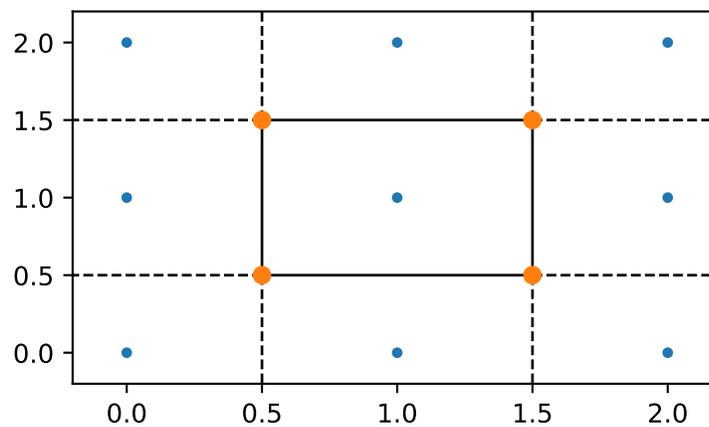

### Examples

Voronoi diagram for a set of point:

```
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2],
...                    [2, 0], [2, 1], [2, 2]])
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> voronoi_plot_2d(vor)
>>> plt.show()
```

The Voronoi vertices:

```
>>> vor.vertices
array([[ 0.5,  0.5],
       [ 1.5,  0.5],
       [ 0.5,  1.5],
       [ 1.5,  1.5]])
```

There is a single finite Voronoi region, and four finite Voronoi ridges:

```
>>> vor.regions
[[[], [-1, 0], [-1, 1], [1, -1, 0], [3, -1, 2], [-1, 3], [-1, 2], [3, 2, 0, 1], [2,
↪ -1, 0], [3, -1, 1]]
>>> vor.ridge_vertices
[[-1, 0], [-1, 0], [-1, 1], [-1, 1], [0, 1], [-1, 3], [-1, 2], [2, 3], [-1, 3], [-
↪ 1, 2], [0, 2], [1, 3]]
```

The ridges are perpendicular between lines drawn between the following input points:

```
>>> vor.ridge_points
array([[0, 1],
       [0, 3],
       [6, 3],
       [6, 7],
```

```
[3, 4],
[5, 8],
[5, 2],
[5, 4],
[8, 7],
[2, 1],
[4, 1],
[4, 7]], dtype=int32)
```

**Attributes**

<code>points</code>	(ndarray of double, shape (npoints, ndim)) Coordinates of input points.
<code>vertices</code>	(ndarray of double, shape (nvertices, ndim)) Coordinates of the Voronoi vertices.
<code>ridge_points</code>	(ndarray of ints, shape (nridges, 2)) Indices of the points between which each Voronoi ridge lies.
<code>ridge_vertices</code>	(list of list of ints, shape (nridges, *)) Indices of the Voronoi vertices forming each Voronoi ridge.
<code>regions</code>	(list of list of ints, shape (nregions, *)) Indices of the Voronoi vertices forming each Voronoi region. -1 indicates vertex outside the Voronoi diagram.
<code>point_region</code>	(list of ints, shape (npoints)) Index of the Voronoi region for each input point. If qhull option "Qc" was not specified, the list will contain -1 for points that are not associated with a Voronoi region.

**Methods**

<code>add_points(points[, restart])</code>	Process a set of additional new points.
<code>close()</code>	Finish incremental processing.

`Voronoi.add_points` (*points*, *restart=False*)  
 Process a set of additional new points.

**Parameters**

- points** : ndarray  
 New points to add. The dimensionality should match that of the initial points.
- restart** : bool, optional  
 Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**

- QhullError**  
 Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

`close`

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

`Voronoi.close` ()  
 Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**class** `scipy.spatial.SphericalVoronoi` (*points*, *radius=None*, *center=None*, *threshold=1e-06*)  
 Voronoi diagrams on the surface of a sphere.

New in version 0.18.0.

**Parameters**

- points** : ndarray of floats, shape (npoints, 3)  
 Coordinates of points to construct a spherical Voronoi diagram from
- radius** : float, optional  
 Radius of the sphere (Default: 1)
- center** : ndarray of floats, shape (3,)  
 Center of sphere (Default: origin)
- threshold** : float  
 Threshold for detecting duplicate points and mismatches between points and sphere parameters. (Default: 1e-06)

**Raises**

- ValueError**  
 If there are duplicates in *points*. If the provided *radius* is not consistent with *points*.

**See also:**

**Voronoi** Conventional Voronoi diagrams in N dimensions.

### Notes

The spherical Voronoi diagram algorithm proceeds as follows. The Convex Hull of the input points (generators) is calculated, and is equivalent to their Delaunay triangulation on the surface of the sphere [Caroli]. A 3D Delaunay tetrahedralization is obtained by including the origin of the coordinate system as the fourth vertex of each simplex of the Convex Hull. The circumcenters of all tetrahedra in the system are calculated and projected to the surface of the sphere, producing the Voronoi vertices. The Delaunay tetrahedralization neighbour information is then used to order the Voronoi region vertices around each generator. The latter approach is substantially less sensitive to floating point issues than angle-based methods of Voronoi region vertex sorting.

The surface area of spherical polygons is calculated by decomposing them into triangles and using L'Huilier's Theorem to calculate the spherical excess of each triangle [Weisstein]. The sum of the spherical excesses is multiplied by the square of the sphere radius to obtain the surface area of the spherical polygon. For nearly-degenerate spherical polygons an area of approximately 0 is returned by default, rather than attempting the unstable calculation.

Empirical assessment of spherical Voronoi algorithm performance suggests quadratic time complexity (loglinear is optimal, but algorithms are more challenging to implement). The reconstitution of the surface area of the sphere, measured as the sum of the surface areas of all Voronoi regions, is closest to 100 % for larger (>> 10) numbers of generators.

### Examples

```
>>> from matplotlib import colors
>>> from mpl_toolkits.mplot3d.art3d import Poly3DCollection
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import SphericalVoronoi
>>> from mpl_toolkits.mplot3d import proj3d
>>> # set input data
>>> points = np.array([[0, 0, 1], [0, 0, -1], [1, 0, 0],
...                   [0, 1, 0], [0, -1, 0], [-1, 0, 0], ])
>>> center = np.array([0, 0, 0])
>>> radius = 1
>>> # calculate spherical Voronoi diagram
```

```

>>> sv = SphericalVoronoi(points, radius, center)
>>> # sort vertices (optional, helpful for plotting)
>>> sv.sort_vertices_of_regions()
>>> # generate plot
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> # plot the unit sphere for reference (optional)
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
>>> # plot generator points
>>> ax.scatter(points[:, 0], points[:, 1], points[:, 2], c='b')
>>> # plot Voronoi vertices
>>> ax.scatter(sv.vertices[:, 0], sv.vertices[:, 1], sv.vertices[:, 2],
...           c='g')
>>> # indicate Voronoi regions (as Euclidean polygons)
>>> for region in sv.regions:
...     random_color = colors.rgb2hex(np.random.rand(3))
...     polygon = Poly3DCollection([sv.vertices[region]], alpha=1.0)
...     polygon.set_color(random_color)
...     ax.add_collection3d(polygon)
>>> plt.show()
    
```

### Attributes

points	(double array of shape (npoints, 3)) the points in 3D to generate the Voronoi diagram from
radius	(double) radius of the sphere Default: None (forces estimation, which is less precise)
center	(double array of shape (3,)) center of the sphere Default: None (assumes sphere is centered at origin)
vertices	(double array of shape (nvertices, 3)) Voronoi vertices corresponding to points
regions	(list of list of integers of shape (npoints, _)) the n-th entry is a list consisting of the indices of the vertices belonging to the n-th point in points

**Methods**

---

<code>sort_vertices_of_regions()</code>	For each region in regions, it sorts the indices of the Voronoi vertices such that the resulting points are in a clockwise or counterclockwise order around the generator point.
---	--

---

**SphericalVoronoi.sort\_vertices\_of\_regions()**

For each region in regions, it sorts the indices of the Voronoi vertices such that the resulting points are in a clockwise or counterclockwise order around the generator point.

This is done as follows: Recall that the n-th region in regions surrounds the n-th generator in points and that the k-th Voronoi vertex in vertices is the projected circumcenter of the tetrahedron obtained by the k-th triangle in `_tri.simplices` (and the origin). For each region n, we choose the first triangle (=Voronoi vertex) in `_tri.simplices` and a vertex of that triangle not equal to the center n. These determine a unique neighbor of that triangle, which is then chosen as the second triangle. The second triangle will have a unique vertex not equal to the current vertex or the center. This determines a unique neighbor of the second triangle, which is then chosen as the third triangle and so forth. We proceed through all the triangles (=Voronoi vertices) belonging to the generator in points and obtain a sorted version of the vertices of its surrounding region.

**class** `scipy.spatial.HalfspaceIntersection` (*halfspaces*, *interior\_point*, *incremental=False*, *qhull\_options=None*)

Halfspace intersections in N dimensions.

New in version 0.19.0.

<b>Parameters</b>	<p><b>halfspaces</b> : ndarray of floats, shape (nineq, ndim+1) Stacked Inequalities of the form <math>Ax + b \leq 0</math> in format [A; b]</p> <p><b>interior_point</b> : ndarray of floats, shape (ndim,) Point clearly inside the region defined by halfspaces. Also called a feasible point, it can be obtained by linear programming.</p> <p><b>incremental</b> : bool, optional Allow adding new halfspaces incrementally. This takes up some additional resources.</p> <p><b>qhull_options</b> : str, optional Additional options to pass to Qhull. See Qhull manual for details. (Default: "Qx" for ndim &gt; 4 and "" otherwise) Option "H" is always enabled.</p>
<b>Raises</b>	<p><b>QhullError</b> Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.</p> <p><b>ValueError</b> Raised if an incompatible array is given as input.</p>

**Notes**

The intersections are computed using the [Qhull library](#). This reproduces the "qhalf" functionality of Qhull.

**References**

[[Qhull](#)], [[R395](#)]

**Examples**

Halfspace intersection of planes forming some polygon

```

>>> from scipy.spatial import HalfspaceIntersection
>>> import numpy as np
>>> halfspaces = np.array([[ -1,  0.,  0.],
...                       [ 0., -1.,  0.],
...                       [ 2.,  1., -4.],
...                       [-0.5, 1., -2.]])
>>> feasible_point = np.array([0.5, 0.5])
>>> hs = HalfspaceIntersection(halfspaces, feasible_point)

```

Plot halfspaces as filled regions and intersection points:

```

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot('111', aspect='equal')
>>> xlim, ylim = (-1, 3), (-1, 3)
>>> ax.set_xlim(xlim)
>>> ax.set_ylim(ylim)
>>> x = np.linspace(-1, 3, 100)
>>> symbols = ['- ', '+ ', 'x ', '* ']
>>> signs = [0, 0, -1, -1]
>>> fmt = {"color": None, "edgecolor": "b", "alpha": 0.5}
>>> for h, sym, sign in zip(halfspaces, symbols, signs):
...     hlist = h.tolist()
...     fmt["hatch"] = sym
...     if h[1]== 0:
...         ax.axvline(-h[2]/h[0], label='{}x+{}y+{}=0'.format(*hlist))
...         xi = np.linspace(xlim[sign], -h[2]/h[0], 100)
...         ax.fill_between(xi, ylim[0], ylim[1], **fmt)
...     else:
...         ax.plot(x, (-h[2]-h[0]*x)/h[1], label='{}x+{}y+{}=0'.format(*hlist))
...         ax.fill_between(x, (-h[2]-h[0]*x)/h[1], ylim[sign], **fmt)
>>> x, y = zip(*hs.intersections)
>>> ax.plot(x, y, 'o', markersize=8)

```

By default, qhull does not provide with a way to compute an interior point. This can easily be computed using linear programming. Considering halfspaces of the form  $Ax + b \leq 0$ , solving the linear program:

$$\begin{aligned} & \max y \\ & \text{s.t. } Ax + y||A_i|| \leq -b \end{aligned}$$

With  $A_i$  being the rows of  $A$ , i.e. the normals to each plane.

Will yield a point  $x$  that is furthest inside the convex polyhedron. To be precise, it is the center of the largest hypersphere of radius  $y$  inscribed in the polyhedron. This point is called the Chebyshev center of the polyhedron (see [R395] 4.3.1, pp148-149). The equations outputted by Qhull are always normalized.

```

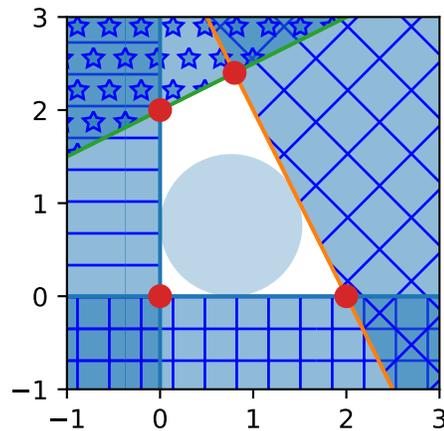

>>> from scipy.optimize import linprog
>>> from matplotlib.patches import Circle
>>> norm_vector = np.reshape(np.linalg.norm(halfspaces[:, :-1], axis=1),
...                          (halfspaces.shape[0], 1))
>>> c = np.zeros((halfspaces.shape[1],))
>>> c[-1] = -1
>>> A = np.hstack((halfspaces[:, :-1], norm_vector))
>>> b = - halfspaces[:, -1:]
>>> res = linprog(c, A_ub=A, b_ub=b)
>>> x = res.x[:-1]
>>> y = res.x[-1]
>>> circle = Circle(x, radius=y, alpha=0.3)

```

```

>>> ax.add_patch(circle)
>>> plt.legend(bbox_to_anchor=(1.6, 1.0))
>>> plt.show()

```

### Attributes

halfspaces	(ndarray of double, shape (nineq, ndim+1)) Input halfspaces.
interior_point :ndarray of floats, shape (ndim,)	Input interior point.
intersections	(ndarray of double, shape (ninter, ndim)) Intersections of all halfspaces.
dual_points	(ndarray of double, shape (nineq, ndim)) Dual points of the input halfspaces.
dual_facets	(list of lists of ints) Indices of points forming the (non necessarily simplicial) facets of the dual convex hull.
dual_vertices	(ndarray of ints, shape (nvertices,)) Indices of halfspaces forming the vertices of the dual convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.
dual_equations	(ndarray of double, shape (nfacet, ndim+1)) [normal, offset] forming the hyperplane equation of the dual facet (see <a href="#">Qhull documentation</a> for more).
dual_area	(float) Area of the dual convex hull
dual_volume	(float) Volume of the dual convex hull

### Methods

<code>add_halfspaces(halfspaces[, restart])</code>	Process a set of additional new halfspaces.
<code>close()</code>	Finish incremental processing.

`HalfspaceIntersection.add_halfspaces(halfspaces, restart=False)`

Process a set of additional new halfspaces.

**Parameters** `halfspaces` : ndarray

New halfspaces to add. The dimensionality should match that of the initial halfspaces.

`restart` : bool, optional

**Raises**

**QhullError**

Whether to restart processing from scratch, rather than adding halfspaces incrementally.

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

`close`

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add halfspaces incrementally. Incremental addition of halfspaces is also not possible after `close` has been called.

`HalfspaceIntersection.close()`  
 Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

### 5.24.3 Plotting Helpers

<code>del aunay_plot_2d(tri[, ax])</code>	Plot the given Delaunay triangulation in 2-D
<code>convex_hull_plot_2d(hull[, ax])</code>	Plot the given convex hull diagram in 2-D
<code>voronoi_plot_2d(vor[, ax])</code>	Plot the given Voronoi diagram in 2-D

`scipy.spatial.delaunay_plot_2d(tri, ax=None)`  
 Plot the given Delaunay triangulation in 2-D

**Parameters** **tri** : `scipy.spatial.Delaunay` instance  
 Triangulation to plot  
**ax** : `matplotlib.axes.Axes` instance, optional  
 Axes to plot on  
**Returns** **fig** : `matplotlib.figure.Figure` instance  
 Figure for the plot

**See also:**

`Delaunay`, `matplotlib.pyplot.triplot`

**Notes**

Requires Matplotlib.

`scipy.spatial.convex_hull_plot_2d(hull, ax=None)`  
 Plot the given convex hull diagram in 2-D

**Parameters** **hull** : `scipy.spatial.ConvexHull` instance  
 Convex hull to plot  
**ax** : `matplotlib.axes.Axes` instance, optional  
 Axes to plot on  
**Returns** **fig** : `matplotlib.figure.Figure` instance  
 Figure for the plot

**See also:**

`ConvexHull`

**Notes**

Requires Matplotlib.

```
scipy.spatial.voronoi_plot_2d(vor, ax=None, **kw)
```

Plot the given Voronoi diagram in 2-D

**Parameters**

- vor** : scipy.spatial.Voronoi instance  
Diagram to plot
- ax** : matplotlib.axes.Axes instance, optional  
Axes to plot on
- show\_points**: **bool, optional**  
Add the Voronoi points to the plot.
- show\_vertices** : bool, optional  
Add the Voronoi vertices to the plot.
- line\_colors** : string, optional  
Specifies the line color for polygon boundaries
- line\_width** : float, optional  
Specifies the line width for polygon boundaries
- line\_alpha**: **float, optional**  
Specifies the line alpha for polygon boundaries

**Returns**

- fig** : matplotlib.figure.Figure instance  
Figure for the plot

**See also:**

*Voronoi*

**Notes**

Requires Matplotlib.

**See also:**

*Tutorial*

## 5.24.4 Simplex representation

The simplices (triangles, tetrahedra, ...) appearing in the Delaunay tessellation (N-dim simplices), convex hull facets, and Voronoi ridges (N-1 dim simplices) are represented in the following scheme:

```
tess = Delaunay(points)
hull = ConvexHull(points)
voro = Voronoi(points)

# coordinates of the j-th vertex of the i-th simplex
tess.points[tess.simplices[i, j], :] # tessellation element
hull.points[hull.simplices[i, j], :] # convex hull facet
voro.vertices[voro.ridge_vertices[i, j], :] # ridge between Voronoi cells
```

For Delaunay triangulations and convex hulls, the neighborhood structure of the simplices satisfies the condition:

`tess.neighbors[i, j]` is the neighboring simplex of the i-th simplex, opposite to the j-vertex. It is -1 in case of no neighbor.

Convex hull facets also define a hyperplane equation:

```
(hull.equations[i, :-1] * coord).sum() + hull.equations[i, -1] == 0
```

Similar hyperplane equations for the Delaunay triangulation correspond to the convex hull facets on the corresponding  $N+1$  dimensional paraboloid.

The Delaunay triangulation objects offer a method for locating the simplex containing a given point, and barycentric coordinate computations.

## Functions

<code>tsearch(tri, xi)</code>	Find simplices containing the given points.
<code>distance_matrix(x, y[, p, threshold])</code>	Compute the distance matrix.
<code>minkowski_distance(x, y[, p])</code>	Compute the $L^{**p}$ distance between two arrays.
<code>minkowski_distance_p(x, y[, p])</code>	Compute the $p$ -th power of the $L^{**p}$ distance between two arrays.
<code>procrustes(data1, data2)</code>	Procrustes analysis, a similarity test for two data sets.

`scipy.spatial.tsearch(tri, xi)`

Find simplices containing the given points. This function does the same thing as `Delaunay.find_simplex`.

New in version 0.9.

**See also:**

`Delaunay.find_simplex`

`scipy.spatial.distance_matrix(x, y, p=2, threshold=1000000)`

Compute the distance matrix.

Returns the matrix of all pair-wise distances.

**Parameters** `x` : (M, K) array\_like

Matrix of M vectors in K dimensions.

`y` : (N, K) array\_like

Matrix of N vectors in K dimensions.

`p` : float,  $1 \leq p \leq \text{infinity}$

Which Minkowski  $p$ -norm to use.

**threshold** : positive int

If  $M * N * K > \text{threshold}$ , algorithm uses a Python loop instead of large

temporary arrays.

**Returns**

**result** : (M, N) ndarray

Matrix containing the distance from every vector in  $x$  to every vector in  $y$ .

### Examples

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix([[0,0], [0,1]], [[1,0], [1,1]])
array([[ 1.         ,  1.41421356],
       [ 1.41421356,  1.         ]])
```

`scipy.spatial.minkowski_distance(x, y, p=2)`

Compute the  $L^{**p}$  distance between two arrays.

**Parameters** `x` : (M, K) array\_like

Input array.

`y` : (N, K) array\_like

Input array.

`p` : float,  $1 \leq p \leq \text{infinity}$

Which Minkowski p-norm to use.

### Examples

```
>>> from scipy.spatial import minkowski_distance
>>> minkowski_distance([[0,0],[0,0]], [[1,1],[0,1]])
array([ 1.41421356,  1.         ])
```

`scipy.spatial.minkowski_distance_p(x, y, p=2)`

Compute the p-th power of the L\*\*p distance between two arrays.

For efficiency, this function computes the L\*\*p distance but does not extract the pth root. If  $p$  is 1 or infinity, this is equal to the actual L\*\*p distance.

**Parameters**

- x** : (M, K) array\_like  
Input array.
- y** : (N, K) array\_like  
Input array.
- p** : float,  $1 \leq p \leq \text{infinity}$   
Which Minkowski p-norm to use.

### Examples

```
>>> from scipy.spatial import minkowski_distance_p
>>> minkowski_distance_p([[0,0],[0,0]], [[1,1],[0,1]])
array([2, 1])
```

`scipy.spatial.procrustes(data1, data2)`

Procrustes analysis, a similarity test for two data sets.

Each input matrix is a set of points or vectors (the rows of the matrix). The dimension of the space is the number of columns of each matrix. Given two identically sized matrices, procrustes standardizes both such that:

- $\text{tr}(AA^T) = 1$ .
- Both sets of points are centered around the origin.

Procrustes ([R410], [R411]) then applies the optimal transform to the second matrix (including scaling/dilation, rotations, and reflections) to minimize  $M^2 = \sum (\text{data1} - \text{data2})^2$ , or the sum of the squares of the pointwise differences between the two input datasets.

This function was not designed to handle datasets with different numbers of datapoints (rows). If two data sets have different dimensionality (different number of columns), simply add columns of zeros to the smaller of the two.

**Parameters**

- data1** : array\_like  
Matrix, n rows represent points in k (columns) space *data1* is the reference data, after it is standardised, the data from *data2* will be transformed to fit the pattern in *data1* (must have >1 unique points).
- data2** : array\_like  
n rows of data in k space to be fit to *data1*. Must be the same shape (numrows, numcols) as *data1* (must have >1 unique points).

**Returns**

- mtx1** : array\_like  
A standardized version of *data1*.
- mtx2** : array\_like  
The orientation of *data2* that best fits *data1*. Centered, but not necessarily  $\text{tr}(AA^T) = 1$ .
- disparity** : float  
 $M^2$  as defined above.

**Raises**

- ValueError**  
If the input arrays are not two-dimensional. If the shape of the input arrays is different. If the input arrays have zero columns or zero rows.

**See also:**

`scipy.linalg.orthogonal_procrustes`  
**`scipy.spatial.distance.directed_hausdorff`**

Another similarity test for two data sets

**Notes**

- The disparity should not depend on the order of the input matrices, but the output matrices will, as only the first output matrix is guaranteed to be scaled such that  $tr(AA^T) = 1$ .
- Duplicate data points are generally ok, duplicating a data point will increase its effect on the procrustes fit.
- The disparity scales as the number of points per input matrix.

**References**

[R410], [R411]

**Examples**

```
>>> from scipy.spatial import procrustes
```

The matrix b is a rotated, shifted, scaled and mirrored version of a here:

```
>>> a = np.array([[1, 3], [1, 2], [1, 1], [2, 1]], 'd')
>>> b = np.array([[4, -2], [4, -4], [4, -6], [2, -6]], 'd')
>>> mtx1, mtx2, disparity = procrustes(a, b)
>>> round(disparity)
0.0
```

## 5.25 Distance computations (`scipy.spatial.distance`)

### 5.25.1 Function Reference

Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.

<code>pdist(X[, metric])</code>	Pairwise distances between observations in n-dimensional space.
<code>cdist(XA, XB[, metric])</code>	Computes distance between each pair of the two collections of inputs.
<code>squareform(X[, force, checks])</code>	Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.
<code>directed_hausdorff(u, v[, seed])</code>	Computes the directed Hausdorff distance between two N-D arrays.

`scipy.spatial.distance.pdist` (*X*, *metric*='euclidean', \*args, \*\*kwargs)

Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

- Parameters**
- X** : ndarray  
An m by n array of m original observations in an n-dimensional space.
  - metric** : str or function, optional  
The distance metric to use. The distance function can be 'braycurtis',

'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.

**\*args** : tuple. Deprecated.

Additional arguments should be passed as keyword arguments

**\*\*kwargs** : dict, optional

Extra arguments to *metric*: refer to each metric documentation for a list of all possible arguments.

Some possible arguments:

**p** : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.

**w** : ndarray The weight vector for metrics that support weights (e.g., Minkowski).

**V** : ndarray The variance vector for standardized Euclidean. Default: var(X, axis=0, ddof=1)

**VI** : ndarray The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(X.T)).T

**out** : ndarray. The output array If not None, condensed distance matrix Y is stored in this array. Note: metric independent, it will become a regular keyword arg in a future scipy version

**Returns**     **Y** : ndarray

Returns a condensed distance matrix Y. For each *i* and *j* (where  $i < j < m$ ), where *m* is the number of original observations. The metric  $\text{dist}(u=X[i], v=X[j])$  is computed and stored in entry *ij*.

**See also:**

**squareform** converts between condensed distance matrices and square distance matrices.

**Notes**

See `squareform` for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. `Y = pdist(X, 'euclidean')`

Computes the distance between *m* points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as *m* *n*-dimensional row vectors in the matrix *X*.

2. `Y = pdist(X, 'minkowski', p=2.)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  (p-norm) where  $p \geq 1$ .

3. `Y = pdist(X, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = pdist(X, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two *n*-vectors *u* and *v* is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}$$

*V* is the variance vector; *V*[*i*] is the variance computed over all the *i*'th components of the points. If not passed, it is automatically computed.

5. `Y = pdist(X, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6.Y = pdist(X, 'cosine')

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|*\|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7.Y = pdist(X, 'correlation')

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8.Y = pdist(X, 'hamming')

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9.Y = pdist(X, 'jaccard')

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree.

10.Y = pdist(X, 'chebyshev')

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|$$

11.Y = pdist(X, 'canberra')

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

12.Y = pdist(X, 'braycurtis')

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i + v_i|}$$

13.Y = pdist(X, 'mahalanobis', VI=None)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u - v)(1/V)(u - v)^T}$  where  $(1/V)$  (the VI variable) is the inverse covariance. If VI is not None, VI will be used as the inverse covariance matrix.

14.Y = pdist(X, 'yule')

Computes the Yule distance between each pair of boolean vectors. (see yule function documentation)

15.Y = pdist(X, 'matching')

Synonym for 'hamming'.

```
16.Y = pdist(X, 'dice')
```

Computes the Dice distance between each pair of boolean vectors. (see dice function documentation)

```
17.Y = pdist(X, 'kulsinski')
```

Computes the Kulsinski distance between each pair of boolean vectors. (see kulsinski function documentation)

```
18.Y = pdist(X, 'rogerstanimoto')
```

Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see rogerstanimoto function documentation)

```
19.Y = pdist(X, 'russellrao')
```

Computes the Russell-Rao distance between each pair of boolean vectors. (see russellrao function documentation)

```
20.Y = pdist(X, 'sokalmichener')
```

Computes the Sokal-Michener distance between each pair of boolean vectors. (see sokalmichener function documentation)

```
21.Y = pdist(X, 'sokalsneath')
```

Computes the Sokal-Sneath distance between each pair of boolean vectors. (see sokalsneath function documentation)

```
22.Y = pdist(X, 'wminkowski', p=2, w=w)
```

Computes the weighted Minkowski distance between each pair of vectors. (see wminkowski function documentation)

```
23.Y = pdist(X, f)
```

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = pdist(X, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = pdist(X, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function sokalsneath. This would result in sokalsneath being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax.:

```
dm = pdist(X, 'sokalsneath')
```

```
scipy.spatial.distance.cdist(XA, XB, metric='euclidean', *args, **kwargs)
```

Computes distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

**Parameters**    **XA** : ndarray

An  $m_A$  by  $n$  array of  $m_A$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.

**XB** : ndarray

An  $m_B$  by  $n$  array of  $m_B$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.

**metric** : str or callable, optional

The distance metric to use. If a string, the distance function can be 'bray-curtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'wminkowski', 'yule'.

**\*args** : tuple. Deprecated.

Additional arguments should be passed as keyword arguments

**\*\*kwargs** : dict, optional

Extra arguments to *metric*: refer to each metric documentation for a list of all possible arguments.

Some possible arguments:

**p** : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.

**w** : ndarray The weight vector for metrics that support weights (e.g., Minkowski).

**V** : ndarray The variance vector for standardized Euclidean. Default: `var(vstack([XA, XB]), axis=0, ddof=1)`

**VI** : ndarray The inverse of the covariance matrix for Mahalanobis. Default: `inv(cov(vstack([XA, XB].T))).T`

**out** : ndarray The output array If not None, the distance matrix Y is stored in this array. Note: metric independent, it will become a regular keyword arg in a future scipy version

**Returns** **Y** : ndarray

A  $m_A$  by  $m_B$  distance matrix is returned. For each  $i$  and  $j$ , the metric `dist(u=XA[i], v=XB[j])` is computed and stored in the  $ij$  th entry.

**Raises** **ValueError**

An exception is thrown if *XA* and *XB* do not have the same number of columns.

### Notes

The following are common calling conventions:

1. `Y = cdist(XA, XB, 'euclidean')`

Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix *X*.

2. `Y = cdist(XA, XB, 'minkowski', p=2.)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  ( $p$ -norm) where  $p \geq 1$ .

3. `Y = cdist(XA, XB, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = cdist(XA, XB, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two vectors *u* and *v* is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}.$$

*V* is the variance vector; *V*[*i*] is the variance computed over all the *i*'th components of the points. If not passed, it is automatically computed.

5. `Y = cdist(XA, XB, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6.Y = cdist(XA, XB, 'cosine')

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|*\|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7.Y = cdist(XA, XB, 'correlation')

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8.Y = cdist(XA, XB, 'hamming')

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9.Y = cdist(XA, XB, 'jaccard')

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree where at least one of them is non-zero.

10.Y = cdist(XA, XB, 'chebyshev')

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|.$$

11.Y = cdist(XA, XB, 'canberra')

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

12.Y = cdist(XA, XB, 'braycurtis')

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}$$

13.Y = cdist(XA, XB, 'mahalanobis', VI=None)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u - v)(1/V)(u - v)^T}$  where  $(1/V)$  (the VI variable) is the inverse covariance. If VI is not None, VI will be used as the inverse covariance matrix.

14.Y = cdist(XA, XB, 'yule')

Computes the Yule distance between the boolean vectors. (see *yule* function documentation)

15.Y = cdist(XA, XB, 'matching')

Synonym for 'hamming'.

```
16.Y = cdist(XA, XB, 'dice')
```

Computes the Dice distance between the boolean vectors. (see *dice* function documentation)

```
17.Y = cdist(XA, XB, 'kulsinski')
```

Computes the Kulsinski distance between the boolean vectors. (see *kulsinski* function documentation)

```
18.Y = cdist(XA, XB, 'rogerstanimoto')
```

Computes the Rogers-Tanimoto distance between the boolean vectors. (see *rogerstanimoto* function documentation)

```
19.Y = cdist(XA, XB, 'russellrao')
```

Computes the Russell-Rao distance between the boolean vectors. (see *russellrao* function documentation)

```
20.Y = cdist(XA, XB, 'sokalmichener')
```

Computes the Sokal-Michener distance between the boolean vectors. (see *sokalmichener* function documentation)

```
21.Y = cdist(XA, XB, 'sokalsneath')
```

Computes the Sokal-Sneath distance between the vectors. (see *sokalsneath* function documentation)

```
22.Y = cdist(XA, XB, 'wminkowski', p=2., w=w)
```

Computes the weighted Minkowski distance between the vectors. (see *wminkowski* function documentation)

```
23.Y = cdist(XA, XB, f)
```

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = cdist(XA, XB, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = cdist(XA, XB, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function *sokalsneath*. This would result in *sokalsneath* being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

```
dm = cdist(XA, XB, 'sokalsneath')
```

### Examples

Find the Euclidean distances between four 2-D coordinates:

```
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672),
...          (35.1174, -89.9711),
...          (35.9728, -83.9422),
...          (36.1667, -86.7833)]
```

```
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0.        ,  4.7044,  1.6172,  1.8856],
       [ 4.7044,  0.        ,  6.0893,  3.3561],
       [ 1.6172,  6.0893,  0.        ,  2.8477],
       [ 1.8856,  3.3561,  2.8477,  0.        ]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```
>>> a = np.array([[0, 0, 0],
...              [0, 0, 1],
...              [0, 1, 0],
...              [0, 1, 1],
...              [1, 0, 0],
...              [1, 0, 1],
...              [1, 1, 0],
...              [1, 1, 1]])
>>> b = np.array([0.1, 0.2, 0.4])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
       [ 0.9],
       [ 1.3],
       [ 1.5],
       [ 1.5],
       [ 1.7],
       [ 2.1],
       [ 2.3]])
```

`scipy.spatial.distance.squareform(X, force='no', checks=True)`

Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.

**Parameters** **X** : ndarray

Either a condensed or redundant distance matrix.

**force** : str, optional

As with MATLAB(TM), if force is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.

**checks** : bool, optional

If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that  $X - X.T$  is small and  $\text{diag}(X)$  is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

**Returns** **Y** : ndarray

If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

### Notes

1.  $v = \text{squareform}(X)$

Given a square  $d$ -by- $d$  symmetric distance matrix  $X$ ,  $v = \text{squareform}(X)$  returns a  $d * (d-1) / 2$  (or  $\binom{d}{2}$ ) sized vector  $v$ .

$v[\binom{d}{2} - \binom{d-i}{2} + (j-i-1)]$  is the distance between points  $i$  and  $j$ . If  $X$  is non-square or asymmetric, an error is returned.

2.  $X = \text{squareform}(v)$

Given a  $d*(d-1)/2$  sized  $v$  for some integer  $d \geq 2$  encoding distances as described,  $X = \text{squareform}(v)$  returns a  $d$  by  $d$  distance matrix  $X$ . The  $X[i, j]$  and  $X[j, i]$  values are set to  $v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  and all diagonal elements are zero.

In SciPy 0.19.0, `squareform` stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

`scipy.spatial.distance.directed_hausdorff(u, v, seed=0)`

Computes the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

**Parameters**

- u** : (M,N) ndarray  
Input array.
- v** : (O,N) ndarray  
Input array.
- seed** : int or None  
Local `np.random.RandomState` seed. Default is 0, a random shuffling of  $u$  and  $v$  that guarantees reproducibility.

**Returns**

- d** : double  
The directed Hausdorff distance between arrays  $u$  and  $v$ ,
- index\_1** : int  
index of point contributing to Hausdorff pair in  $u$
- index\_2** : int  
index of point contributing to Hausdorff pair in  $v$

`scipy.spatial.procrustes`

Another similarity test for two data sets

### Notes

Uses the early break technique and the random sampling approach described by [R409]. Although worst-case performance is  $O(m * o)$  (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is  $O(m)$ , which is satisfied by selecting an inner loop distance that is less than `cmax` and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to  $O(m)$ .

New in version 0.19.0.

### References

[R409]

### Examples

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
...              (0.0, 1.0),
...              (-1.0, 0.0),
...              (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
...              (0.0, 2.0),
...              (-2.0, 0.0),
...              (0.0, -4.0)])
```

```
>>> directed_hausdorff(u, v) [0]
2.23606797749979
>>> directed_hausdorff(v, u) [0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```
>>> max(directed_hausdorff(u, v) [0], directed_hausdorff(v, u) [0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```
>>> directed_hausdorff(v, u) [1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

<code>is_valid_dm(D[, tol, throw, name, warning])</code>	Returns True if input array is a valid distance matrix.
<code>is_valid_y(y[, warning, throw, name])</code>	Returns True if the input array is a valid condensed distance matrix.
<code>num_obs_dm(d)</code>	Returns the number of original observations that correspond to a square, redundant distance matrix.
<code>num_obs_y(Y)</code>	Returns the number of original observations that correspond to a condensed distance matrix.

`scipy.spatial.distance.is_valid_dm(D, tol=0.0, throw=False, name='D', warning=False)`

Returns True if input array is a valid distance matrix.

Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.

<b>Parameters</b>	<b>D</b> : ndarray	The candidate object to test for validity.
	<b>tol</b> : float, optional	The distance matrix should be symmetric. <i>tol</i> is the maximum difference between entries $i_j$ and $j_i$ for the distance metric to be considered symmetric.
	<b>throw</b> : bool, optional	An exception is thrown if the distance matrix passed is not valid.
	<b>name</b> : str, optional	The name of the variable to checked. This is useful if <i>throw</i> is set to True so the offending variable can be identified in the exception message when an exception is thrown.
	<b>warning</b> : bool, optional	Instead of throwing an exception, a warning message is raised.
<b>Returns</b>	<b>valid</b> : bool	True if the variable <i>D</i> passed is a valid distance matrix.

#### Notes

Small numerical differences in *D* and *D.T* and non-zerosness of the diagonal are ignored if they are within the tolerance specified by *tol*.

`scipy.spatial.distance.is_valid_y(y, warning=False, throw=False, name=None)`

Returns True if the input array is a valid condensed distance matrix.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient  $\binom{n}{2}$  for some positive integer  $n$ .

**Parameters** **y** : ndarray  
The condensed distance matrix.

**warning** : bool, optional  
Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. *name* is used when referencing the offending variable.

**throw** : bool, optional  
Throws an exception if the variable passed is not a valid condensed distance matrix.

**name** : bool, optional  
Used when referencing the offending variable in the warning or exception message.

`scipy.spatial.distance.num_obs_dm(d)`

Returns the number of original observations that correspond to a square, redundant distance matrix.

**Parameters** **d** : ndarray  
The target distance matrix.

**Returns** **num\_obs\_dm** : int  
The number of observations in the redundant distance matrix.

`scipy.spatial.distance.num_obs_y(Y)`

Returns the number of original observations that correspond to a condensed distance matrix.

**Parameters** **Y** : ndarray  
Condensed distance matrix.

**Returns** **n** : int  
The number of observations in the condensed distance matrix *Y*.

Distance functions between two numeric vectors *u* and *v*. Computing distances over a large collection of vectors is inefficient for these functions. Use `pdist` for this purpose.

<code>braycurtis(u, v[, w])</code>	Computes the Bray-Curtis distance between two 1-D arrays.
<code>canberra(u, v[, w])</code>	Computes the Canberra distance between two 1-D arrays.
<code>chebyshev(u, v)</code>	Computes the Chebyshev distance.
<code>cityblock(u, v[, w])</code>	Computes the City Block (Manhattan) distance.
<code>correlation(u, v[, w, centered])</code>	Computes the correlation distance between two 1-D arrays.
<code>cosine(u, v[, w])</code>	Computes the Cosine distance between 1-D arrays.
<code>euclidean(u, v[, w])</code>	Computes the Euclidean distance between two 1-D arrays.
<code>mahalanobis(u, v, VI)</code>	Computes the Mahalanobis distance between two 1-D arrays.
<code>minkowski(u, v[, p, w])</code>	Computes the Minkowski distance between two 1-D arrays.
<code>seuclidean(u, v, V)</code>	Returns the standardized Euclidean distance between two 1-D arrays.
<code>squeuclidean(u, v[, w])</code>	Computes the squared Euclidean distance between two 1-D arrays.
<code>wminkowski(u, v, p, w)</code>	Computes the weighted Minkowski distance between two 1-D arrays.

`scipy.spatial.distance.braycurtis(u, v, w=None)`

Computes the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

$$\sum |u_i - v_i| / \sum |u_i + v_i|$$

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- w** : (N,) array\_like, optional  
The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**braycurtis** : double  
The Bray-Curtis distance between 1-D arrays *u* and *v*.

`scipy.spatial.distance.canberra` (*u*, *v*, *w=None*)

Computes the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- w** : (N,) array\_like, optional  
The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**canberra** : double  
The Canberra distance between vectors *u* and *v*.

#### Notes

When  $u[i]$  and  $v[i]$  are 0 for given *i*, then the fraction  $0/0 = 0$  is used in the calculation.

`scipy.spatial.distance.chebyshev` (*u*, *v*)

Computes the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays *u* and *v*, which is defined as

$$\max_i |u_i - v_i|$$

**Parameters**

- u** : (N,) array\_like  
Input vector.
- v** : (N,) array\_like  
Input vector.

**Returns**

**chebyshev** : double  
The Chebyshev distance between vectors *u* and *v*.

`scipy.spatial.distance.cityblock` (*u*, *v*, *w=None*)

Computes the City Block (Manhattan) distance.

Computes the Manhattan distance between two 1-D arrays *u* and *v*, which is defined as

$$\sum_i |u_i - v_i|$$

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.  
**w** : (N,) array\_like, optional  
 The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns** **cityblock** : double  
 The City Block (Manhattan) distance between vectors *u* and *v*.

`scipy.spatial.distance.correlation` (*u*, *v*, *w=None*, *centered=True*)

Computes the correlation distance between two 1-D arrays. The correlation distance between *u* and *v*, is defined as

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|u - \bar{u}\|_2 \|v - \bar{v}\|_2}$$

where  $\bar{u}$  is the mean of the elements of *u* and  $x \cdot y$  is the dot product of *x* and *y*.

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.  
**w** : (N,) array\_like, optional  
 The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns** **correlation** : double  
 The correlation distance between 1-D array *u* and *v*.

`scipy.spatial.distance.cosine` (*u*, *v*, *w=None*)

Computes the Cosine distance between 1-D arrays. The Cosine distance between *u* and *v*, is defined as

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $u \cdot v$  is the dot product of *u* and *v*.

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.  
**w** : (N,) array\_like, optional  
 The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns** **cosine** : double  
 The Cosine distance between vectors *u* and *v*.

`scipy.spatial.distance.euclidean` (*u*, *v*, *w=None*)

Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays *u* and *v*, is defined as

$$\|u - v\|_2 \left( \sum (w_i |(u_i - v_i)|^2) \right)^{1/2}$$

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.

**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **euclidean** : double  
The Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.mahalanobis` ( $u, v, VI$ )

Computes the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\sqrt{(u - v)V^{-1}(u - v)^T}$$

where  $V$  is the covariance matrix. Note that the argument  $VI$  is the inverse of  $V$ .

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.  
**VI** : ndarray  
The inverse of the covariance matrix.

**Returns** **mahalanobis** : double  
The Mahalanobis distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.minkowski` ( $u, v, p=2, w=None$ )

Computes the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\|u - v\|_p = \left( \sum |u_i - v_i|^p \right)^{1/p}.$$

$$\left( \sum w_i (|u_i - v_i|^p) \right)^{1/p}.$$

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.  
**p** : int  
The order of the norm of the difference  $\|u - v\|_p$ .  
**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **minkowski** : double  
The Minkowski distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.seuclidean` ( $u, v, V$ )

Returns the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between  $u$  and  $v$ .

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.  
**V** : (N,) array\_like  
 $V$  is an 1-D array of component variances. It is usually computed among a larger collection vectors.

**Returns** **seuclidean** : double  
The standardized Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sqeuclidean` (*u*, *v*, *w=None*)  
 Computes the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between *u* and *v* is defined as

$$\|u - v\|_2^2$$

$$\left( \sum (w_i |u_i - v_i|^2) \right)$$

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- w** : (N,) array\_like, optional  
The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**sqeuclidean** : double  
The squared Euclidean distance between vectors *u* and *v*.

`scipy.spatial.distance.wminkowski` (*u*, *v*, *p*, *w*)  
 Computes the weighted Minkowski distance between two 1-D arrays. The weighted Minkowski distance between *u* and *v*, defined as

$$\left( \sum (|w_i (u_i - v_i)|^p) \right)^{1/p} .$$

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- p** : int  
The order of the norm of the difference  $\|u - v\|_p$ .
- w** : (N,) array\_like  
The weight vector.

**Returns**

**wminkowski** : double  
The weighted Minkowski distance between vectors *u* and *v*.

**Notes**

`wminkowski` is DEPRECATED. It implements a definition where weights are powered. It is recommended to use the weighted version of `minkowski` instead. This function will be removed in a future version of `scipy`.

Distance functions between two boolean vectors (representing sets) *u* and *v*. As in the case of numerical vectors, `pdist` is more efficient for computing the distances between all pairs.

<code>dice(u, v[, w])</code>	Computes the Dice dissimilarity between two boolean 1-D arrays.
<code>hamming(u, v[, w])</code>	Computes the Hamming distance between two 1-D arrays.
<code>jaccard(u, v[, w])</code>	Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.
<code>kulsinski(u, v[, w])</code>	Computes the Kulsinski dissimilarity between two boolean 1-D arrays.
<code>rogerstanimoto(u, v[, w])</code>	Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.
<code>russellrao(u, v[, w])</code>	Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.
<code>sokalmichener(u, v[, w])</code>	Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.

Continued on next page

Table 5.242 – continued from previous page

<code>sokalsneath(u, v[, w])</code>	Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.
<code>yule(u, v[, w])</code>	Computes the Yule dissimilarity between two boolean 1-D arrays.

`scipy.spatial.distance.dice` ( $u, v, w=None$ )

Computes the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between  $u$  and  $v$ , is

$$\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

- u** : (N,) ndarray, bool  
Input 1-D array.
- v** : (N,) ndarray, bool  
Input 1-D array.
- w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns**

**dice** : double  
The Dice dissimilarity between 1-D arrays  $u$  and  $v$ .

`scipy.spatial.distance.hamming` ( $u, v, w=None$ )

Computes the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays  $u$  and  $v$ , is simply the proportion of disagreeing components in  $u$  and  $v$ . If  $u$  and  $v$  are boolean vectors, the Hamming distance is

$$\frac{c_{01} + c_{10}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

- u** : (N,) array\_like  
Input array.
- v** : (N,) array\_like  
Input array.
- w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns**

**hamming** : double  
The Hamming distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.jaccard` ( $u, v, w=None$ )

Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays  $u$  and  $v$ , is defined as

$$\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

- u** : (N,) array\_like, bool  
Input array.
- v** : (N,) array\_like, bool  
Input array.

**Returns** **w** : (N,) array\_like, optional  
 The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0  
**jaccard** : double  
 The Jaccard distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.kulsinski` ( $u, v, w=None$ )

Computes the Kulsinski dissimilarity between two boolean 1-D arrays.

The Kulsinski dissimilarity between two boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
 Input array.  
**w** : (N,) array\_like, optional  
 The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0  
**Returns** **kulsinski** : double  
 The Kulsinski distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.rogerstanimoto` ( $u, v, w=None$ )

Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{R}{c_{TT} + c_{FF} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
 Input array.  
**w** : (N,) array\_like, optional  
 The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0  
**Returns** **rogerstanimoto** : double  
 The Rogers-Tanimoto dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.russellrao` ( $u, v, w=None$ )

Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays,  $u$  and  $v$ , is defined as

$$\frac{n - c_{TT}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
 Input array.  
**w** : (N,) array\_like, optional  
 The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **russellrao** : double  
The Russell-Rao dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sokalmichener` ( $u, v, w=None$ )

Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{R}{S + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ ,  $R = 2 * (c_{TF} + c_{FT})$  and  $S = c_{FF} + c_{TT}$ .

**Parameters** **u** : (N,) array\_like, bool  
Input array.  
**v** : (N,) array\_like, bool  
Input array.  
**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **sokalmichener** : double  
The Sokal-Michener dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sokalsneath` ( $u, v, w=None$ )

Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between  $u$  and  $v$ ,

$$\frac{R}{c_{TT} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters** **u** : (N,) array\_like, bool  
Input array.  
**v** : (N,) array\_like, bool  
Input array.  
**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **sokalsneath** : double  
The Sokal-Sneath dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.yule` ( $u, v, w=None$ )

Computes the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

$$\frac{R}{c_{TT} * c_{FF} + \frac{R}{2}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2.0 * c_{TF} * c_{FT}$ .

**Parameters** **u** : (N,) array\_like, bool  
Input array.  
**v** : (N,) array\_like, bool  
Input array.  
**w** : (N,) array\_like, optional  
The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns** **yule** : double

The Yule dissimilarity between vectors  $u$  and  $v$ .

`hamming` also operates over discrete numerical vectors.

## 5.26 Special functions (`scipy.special`)

Nearly all of the functions below are universal functions and follow broadcasting and automatic array-looping rules. Exceptions are noted.

**See also:**

`scipy.special.cython_special` – Typed Cython versions of special functions

### 5.26.1 Error handling

Errors are handled by returning NaNs or other appropriate values. Some of the special function routines can emit warnings or raise exceptions when an error occurs. By default this is disabled; to query and control the current error handling state the following functions are provided.

<code>geterr</code>	Get the current way of handling special-function errors.
<code>seterr</code>	Set how special-function errors are handled.
<code>errstate</code>	Context manager for special-function error handling.
<code>SpecialFunctionWarning</code>	Warning that can be emitted by special functions.
<code>SpecialFunctionError</code>	Exception that can be raised by special functions.

`scipy.special.geterr()`

Get the current way of handling special-function errors.

**Returns** `err` : dict

A dictionary with keys “singular”, “underflow”, “overflow”, “slow”, “loss”, “no\_result”, “domain”, “arg”, and “other”, whose values are from the strings “ignore”, “warn”, and “raise”. The keys represent possible special-function errors, and the values define how these errors are handled.

**See also:**

- seterr** set how special-function errors are handled
- errstate** context manager for special-function error handling
- `numpy.geterr`** similar numpy function for floating-point errors

**Notes**

For complete documentation of the types of special-function errors and treatment options, see `seterr`.

**Examples**

By default all errors are ignored.

```

>>> import scipy.special as sc
>>> for key, value in sorted(sc.geterr().items()):
...     print("{}: {}".format(key, value))
...
arg: ignore
domain: ignore
    
```

```

loss: ignore
no_result: ignore
other: ignore
overflow: ignore
singular: ignore
slow: ignore
underflow: ignore

```

`scipy.special.seterr()`

Set how special-function errors are handled.

**Parameters** **all** : {'ignore', 'warn', 'raise'}, optional

Set treatment for all type of special-function errors at once. The options are:

- 'ignore' Take no action when the error occurs
- 'warn' Print a `SpecialFunctionWarning` when the error occurs (via the Python `warnings` module)
- 'raise' Raise a `SpecialFunctionError` when the error occurs.

The default is to not change the current behavior. If behaviors for additional categories of special-function errors are specified, then `all` is applied first, followed by the additional categories.

**singular** : {'ignore', 'warn', 'raise'}, optional

Treatment for singularities.

**underflow** : {'ignore', 'warn', 'raise'}, optional

Treatment for underflow.

**overflow** : {'ignore', 'warn', 'raise'}, optional

Treatment for overflow.

**slow** : {'ignore', 'warn', 'raise'}, optional

Treatment for slow convergence.

**loss** : {'ignore', 'warn', 'raise'}, optional

Treatment for loss of accuracy.

**no\_result** : {'ignore', 'warn', 'raise'}, optional

Treatment for failing to find a result.

**domain** : {'ignore', 'warn', 'raise'}, optional

Treatment for an invalid argument to a function.

**arg** : {'ignore', 'warn', 'raise'}, optional

Treatment for an invalid parameter to a function.

**other** : {'ignore', 'warn', 'raise'}, optional

Treatment for an unknown error.

**Returns**

**olderr** : dict

Dictionary containing the old settings.

See also:

**geterr** get the current way of handling special-function errors

**errstate** context manager for special-function error handling

**`numpy.seterr`**

similar numpy function for floating-point errors

**Examples**

```

>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> olderr = sc.seterr(singular='raise')

```

```
>>> with raises(sc.SpecialFunctionError):
...     sc.gammaln(0)
...
>>> _ = sc.seterr(**olderr)
```

We can also raise for every category except one.

```
>>> olderr = sc.seterr(all='raise', singular='ignore')
>>> sc.gammaln(0)
inf
>>> with raises(sc.SpecialFunctionError):
...     sc.spence(-1)
...
>>> _ = sc.seterr(**olderr)
```

### class `scipy.special.errstate`

Context manager for special-function error handling.

Using an instance of `errstate` as a context manager allows statements in that context to execute with a known error handling behavior. Upon entering the context the error handling is set with `seterr`, and upon exiting it is restored to what it was before.

**Parameters** **kwargs** : {all, singular, underflow, overflow, slow, loss, no\_result, domain, arg, other}  
 Keyword arguments. The valid keywords are possible special-function errors. Each keyword should have a string value that defines the treatment for the particular type of error. Values must be 'ignore', 'warn', or 'other'. See `seterr` for details.

#### See also:

**geterr** get the current way of handling special-function errors  
**seterr** set how special-function errors are handled  
`numpy.errstate`  
 similar numpy function for floating-point errors

#### Examples

```
>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> with sc.errstate(singular='raise'):
...     with raises(sc.SpecialFunctionError):
...         sc.gammaln(0)
...
>>> sc.gammaln(0)
inf
```

We can also raise on every category except one.

```
>>> with sc.errstate(all='raise', singular='ignore'):
...     sc.gammaln(0)
...     with raises(sc.SpecialFunctionError):
...         sc.spence(-1)
...
inf
```

**exception** `scipy.special.SpecialFunctionWarning`

Warning that can be emitted by special functions.

**exception** `scipy.special.SpecialFunctionError`

Exception that can be raised by special functions.

## 5.26.2 Available functions

### Airy functions

<code>airy(z)</code>	Airy functions and their derivatives.
<code>airye(z)</code>	Exponentially scaled Airy functions and their derivatives.
<code>ai_zeros(nt)</code>	Compute $nt$ zeros and values of the Airy function $Ai$ and its derivative.
<code>bi_zeros(nt)</code>	Compute $nt$ zeros and values of the Airy function $Bi$ and its derivative.
<code>itairy(x)</code>	Integrals of Airy functions

`scipy.special.airy(z) = <ufunc 'airy'>`

Airy functions and their derivatives.

**Parameters** `z` : array\_like

**Returns** `Ai, Aip, Bi, Bip` : ndarrays

Real or complex argument.

Airy functions  $Ai$  and  $Bi$ , and their derivatives  $Aip$  and  $Bip$ .

**See also:**

**airye** exponentially scaled Airy functions.

**Notes**

The Airy functions  $Ai$  and  $Bi$  are two independent solutions of

$$y''(x) = xy(x).$$

For real  $z$  in  $[-10, 10]$ , the computation is carried out by calling the Cephes [R413] `airy` routine, which uses power series summation for small  $z$  and rational minimax approximations for large  $z$ .

Outside this range, the AMOS [R414] `zairy` and `zbiry` routines are employed. They are computed using power series for  $|z| < 1$  and the following relations to modified Bessel functions for larger  $z$  (where  $t \equiv 2z^{3/2}/3$ ):

$$Ai(z) = \frac{1}{\pi\sqrt{3}}K_{1/3}(t)$$

$$Ai'(z) = -\frac{z}{\pi\sqrt{3}}K_{2/3}(t)$$

$$Bi(z) = \sqrt{\frac{z}{3}}(I_{-1/3}(t) + I_{1/3}(t))$$

$$Bi'(z) = \frac{z}{\sqrt{3}}(I_{-2/3}(t) + I_{2/3}(t))$$

**References**

[R413], [R414]

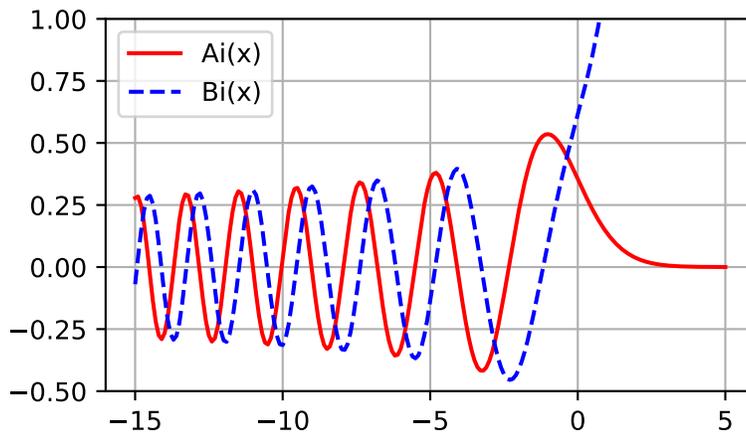

*Examples*

Compute the Airy functions on the interval [-15, 5].

```
>>> from scipy import special
>>> x = np.linspace(-15, 5, 201)
>>> ai, aip, bi, bip = special.airy(x)
```

Plot  $Ai(x)$  and  $Bi(x)$ .

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, ai, 'r', label='Ai(x)')
>>> plt.plot(x, bi, 'b--', label='Bi(x)')
>>> plt.ylim(-0.5, 1.0)
>>> plt.grid()
>>> plt.legend(loc='upper left')
>>> plt.show()
```

`scipy.special.airye(z) = <ufunc 'airye'>`

Exponentially scaled Airy functions and their derivatives.

Scaling:

```
eAi = Ai * exp(2.0/3.0*z*sqrt(z))
eAip = Aip * exp(2.0/3.0*z*sqrt(z))
eBi = Bi * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
eBip = Bip * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
```

**Parameters** `z`: array\_like

**Returns** `eAi, eAip, eBi, eBip`: array\_like  
 Real or complex argument.  
 Airy functions  $Ai$  and  $Bi$ , and their derivatives  $Aip$  and  $Bip$

**See also:**

`airy`

**Notes**

Wrapper for the AMOS [R415] routines *zairy* and *zbiry*.

**References**

[R415]

`scipy.special.ai_zeros` (*nt*)

Compute *nt* zeros and values of the Airy function  $Ai$  and its derivative.

Computes the first *nt* zeros, *a*, of the Airy function  $Ai(x)$ ; first *nt* zeros, *ap*, of the derivative of the Airy function  $Ai'(x)$ ; the corresponding values  $Ai(a')$ ; and the corresponding values  $Ai'(a)$ .

<b>Parameters</b>	<b>nt</b> : int	Number of zeros to compute
<b>Returns</b>	<b>a</b> : ndarray	First <i>nt</i> zeros of $Ai(x)$
	<b>ap</b> : ndarray	First <i>nt</i> zeros of $Ai'(x)$
	<b>ai</b> : ndarray	Values of $Ai(x)$ evaluated at first <i>nt</i> zeros of $Ai'(x)$
	<b>aip</b> : ndarray	Values of $Ai'(x)$ evaluated at first <i>nt</i> zeros of $Ai(x)$

**References**

[R412]

`scipy.special.bi_zeros` (*nt*)

Compute *nt* zeros and values of the Airy function  $Bi$  and its derivative.

Computes the first *nt* zeros, *b*, of the Airy function  $Bi(x)$ ; first *nt* zeros, *b'*, of the derivative of the Airy function  $Bi'(x)$ ; the corresponding values  $Bi(b')$ ; and the corresponding values  $Bi'(b)$ .

<b>Parameters</b>	<b>nt</b> : int	Number of zeros to compute
<b>Returns</b>	<b>b</b> : ndarray	First <i>nt</i> zeros of $Bi(x)$
	<b>bp</b> : ndarray	First <i>nt</i> zeros of $Bi'(x)$
	<b>bi</b> : ndarray	Values of $Bi(x)$ evaluated at first <i>nt</i> zeros of $Bi'(x)$
	<b>bip</b> : ndarray	Values of $Bi'(x)$ evaluated at first <i>nt</i> zeros of $Bi(x)$

**References**

[R428]

`scipy.special.itairy` (*x*) = <ufunc 'itairy'>

Integrals of Airy functions

Calculates the integrals of Airy functions from 0 to *x*.

<b>Parameters</b>	<b>x</b> : array_like	Upper limit of integration (float).
<b>Returns</b>	<b>Apt</b>	Integral of $Ai(t)$ from 0 to <i>x</i> .
	<b>Bpt</b>	Integral of $Bi(t)$ from 0 to <i>x</i> .
	<b>Ant</b>	

`scipy.special.ellipk(m)`

Complete elliptic integral of the first kind.

This function is defined as

$$K(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

**Parameters** **m** : array\_like  
**Returns** **K** : array\_like The parameter of the elliptic integral.  
 Value of the elliptic integral.

**See also:**

**ellipkm1** Complete elliptic integral of the first kind around  $m = 1$   
**ellipkinc** Incomplete elliptic integral of the first kind  
**ellipe** Complete elliptic integral of the second kind  
**ellipeinc** Incomplete elliptic integral of the second kind

**Notes**

For more precision around point  $m = 1$ , use `ellipkm1`, which this function calls.

The parameterization in terms of  $m$  follows that of section 17.2 in [R452]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

**References**

[R452]

`scipy.special.ellipkm1(p) = <ufunc 'ellipkm1'>`

Complete elliptic integral of the first kind around  $m = 1$

This function is defined as

$$K(p) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

where  $m = 1 - p$ .

**Parameters** **p** : array\_like  
**Returns** **K** : ndarray Defines the parameter of the elliptic integral as  $m = 1 - p$ .  
 Value of the elliptic integral.

**See also:**

**ellipk** Complete elliptic integral of the first kind  
**ellipkinc** Incomplete elliptic integral of the first kind  
**ellipe** Complete elliptic integral of the second kind  
**ellipeinc** Incomplete elliptic integral of the second kind

**Notes**

Wrapper for the Cephes [R455] routine `ellpk`.

For  $p \leq 1$ , computation uses the approximation,

$$K(p) \approx P(p) - \log(p)Q(p),$$

where  $P$  and  $Q$  are tenth-order polynomials. The argument  $p$  is used internally rather than  $m$  so that the logarithmic singularity at  $m = 1$  will be shifted to the origin; this preserves maximum accuracy. For  $p > 1$ , the identity

$$K(p) = K(1/p)/\sqrt{p}$$

is used.

### References

[R455]

`scipy.special.ellipkinc(phi, m) = <ufunc 'ellipkinc'>`

Incomplete elliptic integral of the first kind

This function is defined as

$$K(\phi, m) = \int_0^\phi [1 - m \sin(t)^2]^{-1/2} dt$$

This function is also called  $F(\phi, m)$ .

<b>Parameters</b>	<b>phi</b> : array_like	amplitude of the elliptic integral
	<b>m</b> : array_like	parameter of the elliptic integral
<b>Returns</b>	<b>K</b> : ndarray	Value of the elliptic integral

See also:

<b>ellipkm1</b>	Complete elliptic integral of the first kind, near $m = 1$
<b>ellipk</b>	Complete elliptic integral of the first kind
<b>ellipe</b>	Complete elliptic integral of the second kind
<b>ellipeinc</b>	Incomplete elliptic integral of the second kind

### Notes

Wrapper for the Cephes [R453] routine *ellik*. The computation is carried out using the arithmetic-geometric mean algorithm.

The parameterization in terms of  $m$  follows that of section 17.2 in [R454]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

### References

[R453], [R454]

`scipy.special.ellipe(m) = <ufunc 'ellipe'>`

Complete elliptic integral of the second kind

This function is defined as

$$E(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{1/2} dt$$

<b>Parameters</b>	<b>m</b> : array_like	Defines the parameter of the elliptic integral.
<b>Returns</b>	<b>E</b> : ndarray	Value of the elliptic integral.

See also:

**ellipkm1** Complete elliptic integral of the first kind, near  $m = 1$   
**ellipk** Complete elliptic integral of the first kind  
**ellipkinc** Incomplete elliptic integral of the first kind  
**ellipeinc** Incomplete elliptic integral of the second kind

**Notes**

Wrapper for the Cephes [R447] routine *ellpe*.

For  $m > 0$  the computation uses the approximation,

$$E(m) \approx P(1 - m) - (1 - m) \log(1 - m)Q(1 - m),$$

where  $P$  and  $Q$  are tenth-order polynomials. For  $m < 0$ , the relation

$$E(m) = E(m/(m - 1))\sqrt{1 - m}$$

is used.

The parameterization in terms of  $m$  follows that of section 17.2 in [R448]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

**References**

[R447], [R448]

`scipy.special.ellipeinc(phi, m) = <ufunc 'ellipeinc'>`  
 Incomplete elliptic integral of the second kind

This function is defined as

$$E(\phi, m) = \int_0^\phi [1 - m \sin(t)^2]^{1/2} dt$$

**Parameters**

- phi** : array\_like  
amplitude of the elliptic integral.
- m** : array\_like  
parameter of the elliptic integral.

**Returns**

- E** : ndarray  
Value of the elliptic integral.

**See also:**

**ellipkm1** Complete elliptic integral of the first kind, near  $m = 1$   
**ellipk** Complete elliptic integral of the first kind  
**ellipkinc** Incomplete elliptic integral of the first kind  
**ellipe** Complete elliptic integral of the second kind

**Notes**

Wrapper for the Cephes [R449] routine *ellie*.

Computation uses arithmetic-geometric means algorithm.

The parameterization in terms of  $m$  follows that of section 17.2 in [R450]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

## Bessel Functions

$jv(v, z)$	Bessel function of the first kind of real order and complex argument.
$jn(v, z)$	Bessel function of the first kind of real order and complex argument.
$jve(v, z)$	Exponentially scaled Bessel function of order $v$ .
$yn(n, x)$	Bessel function of the second kind of integer order and real argument.
$yv(v, z)$	Bessel function of the second kind of real order and complex argument.
$yve(v, z)$	Exponentially scaled Bessel function of the second kind of real order.
$kn(n, x)$	Modified Bessel function of the second kind of integer order $n$
$kν(v, z)$	Modified Bessel function of the second kind of real order $v$
$kve(v, z)$	Exponentially scaled modified Bessel function of the second kind.
$iv(v, z)$	Modified Bessel function of the first kind of real order.
$ive(v, z)$	Exponentially scaled modified Bessel function of the first kind
$hankel1(v, z)$	Hankel function of the first kind
$hankel1e(v, z)$	Exponentially scaled Hankel function of the first kind
$hankel2(v, z)$	Hankel function of the second kind
$hankel2e(v, z)$	Exponentially scaled Hankel function of the second kind

`scipy.special.jv(v, z) = <ufunc 'jv'>`

Bessel function of the first kind of real order and complex argument.

**Parameters**

- v** : array\_like  
Order (float).
- z** : array\_like  
Argument (float or complex).

**Returns**

- J** : ndarray  
Value of the Bessel function,  $J_v(z)$ .

**See also:**

**jve**  $J_v$  with leading exponential behavior stripped off.

**spherical\_jn**  
spherical Bessel functions.

**Notes**

For positive  $v$  values, the computation is carried out using the AMOS [R511] *zbesj* routine, which exploits the connection to the modified Bessel function  $I_v$ ,

$$J_v(z) = \exp(v\pi i/2)I_v(-iz) \quad (\Im z > 0)$$

$$J_v(z) = \exp(-v\pi i/2)I_v(iz) \quad (\Im z < 0)$$

For negative  $v$  values the formula,

$$J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)$$

is used, where  $Y_v(z)$  is the Bessel function of the second kind, computed using the AMOS routine *zbesy*. Note that the second term is exactly zero for integer  $v$ ; to improve accuracy the second term is explicitly omitted for  $v$  values such that  $v = \text{floor}(v)$ .

Not to be confused with the spherical Bessel functions (see *spherical\_jn*).

### References

[R511]

`scipy.special.jn`(*v*, *z*) = <ufunc 'jn'>

Bessel function of the first kind of real order and complex argument.

**Parameters**

- v** : array\_like  
Order (float).
- z** : array\_like  
Argument (float or complex).

**Returns**

- J** : ndarray  
Value of the Bessel function,  $J_v(z)$ .

See also:

**jve**  $J_v$  with leading exponential behavior stripped off.

**spherical\_jn**  
spherical Bessel functions.

### Notes

For positive *v* values, the computation is carried out using the AMOS [R506] *zbesj* routine, which exploits the connection to the modified Bessel function  $I_v$ ,

$$\begin{aligned} J_v(z) &= \exp(v\pi i/2) I_v(-iz) & (\Im z > 0) \\ J_v(z) &= \exp(-v\pi i/2) I_v(iz) & (\Im z < 0) \end{aligned}$$

For negative *v* values the formula,

$$J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)$$

is used, where  $Y_v(z)$  is the Bessel function of the second kind, computed using the AMOS routine *zbesy*. Note that the second term is exactly zero for integer *v*; to improve accuracy the second term is explicitly omitted for *v* values such that  $v = \text{floor}(v)$ .

Not to be confused with the spherical Bessel functions (see *spherical\_jn*).

### References

[R506]

`scipy.special.jve`(*v*, *z*) = <ufunc 'jve'>

Exponentially scaled Bessel function of order *v*.

Defined as:

```
jve(v, z) = jv(v, z) * exp(-abs(z.imag))
```

**Parameters**

- v** : array\_like  
Order (float).
- z** : array\_like  
Argument (float or complex).

**Returns**

- J** : ndarray  
Value of the exponentially scaled Bessel function.

**Notes**

For positive  $\nu$  values, the computation is carried out using the AMOS [R597] *zbesy* routine, which exploits the connection to the Hankel Bessel functions  $H_\nu^{(1)}$  and  $H_\nu^{(2)}$ ,

$$Y_\nu(z) = \frac{1}{2i}(H_\nu^{(1)} - H_\nu^{(2)}).$$

For negative  $\nu$  values the formula,

$$Y_{-\nu}(z) = Y_\nu(z) \cos(\pi\nu) + J_\nu(z) \sin(\pi\nu)$$

is used, where  $J_\nu(z)$  is the Bessel function of the first kind, computed using the AMOS routine *zbesj*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

**References**

[R597]

`scipy.special.yve` ( $\nu, z$ ) = <ufunc 'yve'>

Exponentially scaled Bessel function of the second kind of real order.

Returns the exponentially scaled Bessel function of the second kind of real order  $\nu$  at complex  $z$ :

```
yve( $\nu, z$ ) = yv( $\nu, z$ ) * exp(-abs( $z$ .imag))
```

**Parameters**  $\nu$  : array\_like

Order (float).

$z$  : array\_like

Argument (float or complex).

**Returns**  $Y$  : ndarray

Value of the exponentially scaled Bessel function.

**Notes**

For positive  $\nu$  values, the computation is carried out using the AMOS [R598] *zbesy* routine, which exploits the connection to the Hankel Bessel functions  $H_\nu^{(1)}$  and  $H_\nu^{(2)}$ ,

$$Y_\nu(z) = \frac{1}{2i}(H_\nu^{(1)} - H_\nu^{(2)}).$$

For negative  $\nu$  values the formula,

$$Y_{-\nu}(z) = Y_\nu(z) \cos(\pi\nu) + J_\nu(z) \sin(\pi\nu)$$

is used, where  $J_\nu(z)$  is the Bessel function of the first kind, computed using the AMOS routine *zbesj*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

**References**

[R598]

`scipy.special.kn` ( $n, x$ ) = <ufunc 'kn'>

Modified Bessel function of the second kind of integer order  $n$

Returns the modified Bessel function of the second kind for integer order  $n$  at real  $z$ .

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions.

**Parameters**  $n$  : array\_like of int

Order of Bessel functions (floats will truncate with a warning)  
**z** : array\_like of float  
**Returns**     **out** : ndarray     Argument at which to evaluate the Bessel functions  
                                   The results

**See also:**

**kv**            Same function, but accepts real order and complex argument  
**kvp**          Derivative of this function

**Notes**

Wrapper for AMOS [R523] routine *zbesk*. For a discussion of the algorithm used, see [R524] and the references therein.

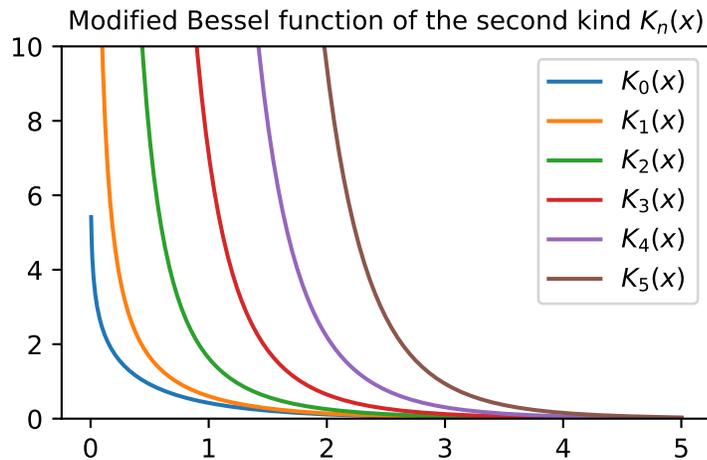

**References**

[R523], [R524]

**Examples**

Plot the function of several orders for real input:

```
>>> from scipy.special import kn
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in range(6):
...     plt.plot(x, kn(N, x), label='$K_{%d}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_n(x)$')
>>> plt.show()
```

Calculate for a single value at multiple orders:

```
>>> kn([4, 5, 6], 1)
array([ 44.23241585, 360.9605896, 3653.83831186])
```

`scipy.special.kv`( $\nu, z$ ) = <ufunc 'kv'>

Modified Bessel function of the second kind of real order  $\nu$

Returns the modified Bessel function of the second kind for real order  $\nu$  at complex  $z$ .

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions. They are defined as those solutions of the modified Bessel equation for which,

$$K_\nu(x) \sim \sqrt{\pi/(2x)} \exp(-x)$$

as  $x \rightarrow \infty$  [R527].

<b>Parameters</b>	<b>v</b> : array_like of float Order of Bessel functions
	<b>z</b> : array_like of complex Argument at which to evaluate the Bessel functions
<b>Returns</b>	<b>out</b> : ndarray The results. Note that input must be of complex type to get complex output, e.g. <code>kv(3, -2+0j)</code> instead of <code>kv(3, -2)</code> .

**See also:**

**kve** This function with leading exponential behavior stripped off.  
**kvp** Derivative of this function

**Notes**

Wrapper for AMOS [R525] routine `zbesk`. For a discussion of the algorithm used, see [R526] and the references therein.

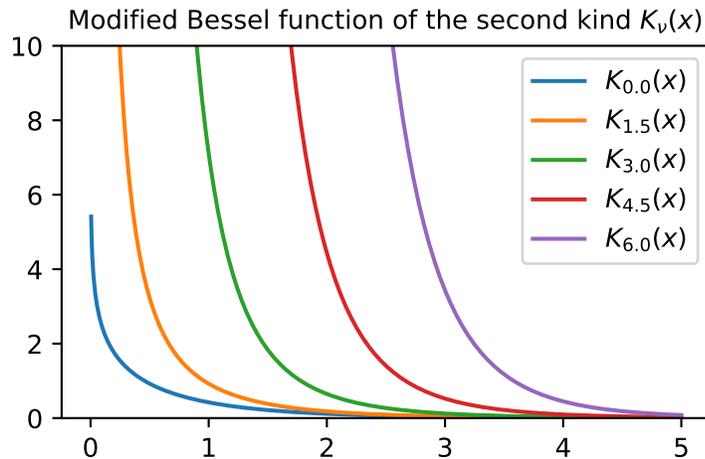

**References**

[R525], [R526], [R527]

**Examples**

Plot the function of several orders for real input:

```
>>> from scipy.special import kv
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in np.linspace(0, 6, 5):
...     plt.plot(x, kv(N, x), label='$K_{%d}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_{\nu}(x)$')
>>> plt.show()
```

Calculate for a single value at multiple orders:

```
>>> kv([4, 4.5, 5], 1+2j)
array([ 0.1992+2.3892j,  2.3493+3.6j    ,  7.2827+3.8104j])
```

`scipy.special.kve` ( $v, z$ ) = <ufunc 'kve'>

Exponentially scaled modified Bessel function of the second kind.

Returns the exponentially scaled, modified Bessel function of the second kind (sometimes called the third kind) for real order  $v$  at complex  $z$ :

```
kve(v, z) = kv(v, z) * exp(z)
```

**Parameters**

- v** : array\_like of float  
Order of Bessel functions
- z** : array\_like of complex  
Argument at which to evaluate the Bessel functions

**Returns**

- out** : ndarray  
The exponentially scaled modified Bessel function of the second kind.

#### Notes

Wrapper for AMOS [R528] routine *zbesk*. For a discussion of the algorithm used, see [R529] and the references therein.

#### References

`scipy.special.iv` ( $v, z$ ) = <ufunc 'iv'>

Modified Bessel function of the first kind of real order.

**Parameters**

- v** : array\_like  
Order. If  $z$  is of real type and negative,  $v$  must be integer valued.
- z** : array\_like of float or complex  
Argument.

**Returns**

- out** : ndarray  
Values of the modified Bessel function.

**See also:**

**kve** This function with leading exponential behavior stripped off.

**Notes**

For real  $z$  and  $v \in [-50, 50]$ , the evaluation is carried out using Temme's method [R499]. For larger orders, uniform asymptotic expansions are applied.

For complex  $z$  and positive  $v$ , the AMOS [R500] *zbesi* routine is called. It uses a power series for small  $z$ , the asymptotic expansion for large  $abs(z)$ , the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for  $I_v(z)$  and  $J_v(z)$  for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v) I_v(z)$$

(valid when the real part of  $z$  is positive). For negative  $v$ , the formula

$$I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v) K_v(z)$$

is used, where  $K_v(z)$  is the modified Bessel function of the second kind, evaluated using the AMOS routine *zbesk*.

**References**

`scipy.special.ive(v, z) = <ufunc 'ive'>`

Exponentially scaled modified Bessel function of the first kind

Defined as:

```
ive(v, z) = iv(v, z) * exp(-abs(z.real))
```

**Parameters** **v** : array\_like of float  
Order.

**z** : array\_like of float or complex  
Argument.

**Returns** **out** : ndarray  
Values of the exponentially scaled modified Bessel function.

**Notes**

For positive  $v$ , the AMOS [R501] *zbesi* routine is called. It uses a power series for small  $z$ , the asymptotic expansion for large  $abs(z)$ , the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for  $I_v(z)$  and  $J_v(z)$  for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v) I_v(z)$$

(valid when the real part of  $z$  is positive). For negative  $v$ , the formula

$$I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v) K_v(z)$$

is used, where  $K_v(z)$  is the modified Bessel function of the second kind, evaluated using the AMOS routine *zbesk*.

`scipy.special.hankel2` ( $v, z$ ) = <ufunc 'hankel2'>

Hankel function of the second kind

**Parameters** **v** : array\_like  
Order (float).  
**z** : array\_like  
Argument (float or complex).

**Returns** **out** : Values of the Hankel function of the second kind.

**See also:****hankel2e** this function with leading exponential behavior stripped off.**Notes**A wrapper for the AMOS [R486] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(2)}(z) = -\frac{2}{i\pi} \exp(i\pi v/2) K_v(z \exp(i\pi/2))$$

where  $K_v$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(2)}(z) = H_v^{(2)}(z) \exp(-i\pi v)$$

is used.

[R486]

`scipy.special.hankel2e` ( $v, z$ ) = <ufunc 'hankel2e'>

Exponentially scaled Hankel function of the second kind

Defined as:

<code>hankel2e(v, z) = hankel2(v, z) * exp(1j * z)</code>
---

**Parameters** **v** : array\_like  
Order (float).  
**z** : array\_like  
Argument (float or complex).

**Returns** **out** : Values of the exponentially scaled Hankel function of the second kind.

**Notes**A wrapper for the AMOS [R487] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(2)}(z) = -\frac{2}{i\pi} \exp\left(\frac{i\pi v}{2}\right) K_v\left(z \exp\left(\frac{i\pi}{2}\right)\right)$$

where  $K_v$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(2)}(z) = H_v^{(2)}(z) \exp(-i\pi v)$$

is used.

The following is not an universal function:

`lmbda(v, x)`

Jahnke-Emden Lambda function, `Lambdav(x)`.

---

`scipy.special.lmbda(v, x)`

Jahnke-Emden Lambda function, `Lambdav(x)`.

This function is defined as [R535],

$$\Lambda_v(x) = \Gamma(v + 1) \frac{J_v(x)}{(x/2)^v},$$

where  $\Gamma$  is the gamma function and  $J_v$  is the Bessel function of the first kind.

**Parameters**

- v** : float  
Order of the Lambda function
- x** : float  
Value at which to evaluate the function and derivatives

**Returns**

- vl** : ndarray  
Values of `Lambda_vi(x)`, for  $vi=v-\text{int}(v)$ ,  $vi=1+v-\text{int}(v)$ , ...,  $vi=v$ .
- dl** : ndarray  
Derivatives `Lambda_vi'(x)`, for  $vi=v-\text{int}(v)$ ,  $vi=1+v-\text{int}(v)$ , ...,  $vi=v$ .

**Zeros of Bessel Functions**

These are not universal functions:

<code>jnjnp_zeros(nt)</code>	Compute zeros of integer-order Bessel functions $J_n$ and $J_n'$ .
<code>jny_n_zeros(n, nt)</code>	Compute $nt$ zeros of Bessel functions $J_n(x)$ , $J_n'(x)$ , $Y_n(x)$ , and $Y_n'(x)$ .
<code>jn_zeros(n, nt)</code>	Compute zeros of integer-order Bessel function $J_n(x)$ .
<code>jnp_zeros(n, nt)</code>	Compute zeros of integer-order Bessel function derivative $J_n'(x)$ .
<code>yn_zeros(n, nt)</code>	Compute zeros of integer-order Bessel function $Y_n(x)$ .
<code>ynp_zeros(n, nt)</code>	Compute zeros of integer-order Bessel function derivative $Y_n'(x)$ .
<code>y0_zeros(nt[, complex])</code>	Compute $nt$ zeros of Bessel function $Y_0(z)$ , and derivative at each zero.
<code>y1_zeros(nt[, complex])</code>	Compute $nt$ zeros of Bessel function $Y_1(z)$ , and derivative at each zero.
<code>y1p_zeros(nt[, complex])</code>	Compute $nt$ zeros of Bessel derivative $Y_1'(z)$ , and value at each zero.

`scipy.special.jnjnp_zeros(nt)`

Compute zeros of integer-order Bessel functions  $J_n$  and  $J_n'$ .

Results are arranged in order of the magnitudes of the zeros.

**Parameters**

- nt** : int  
Number ( $\leq 1200$ ) of zeros to compute

**Returns**

- zo[l-1]** : ndarray  
Value of the  $l$ th zero of  $J_n(x)$  and  $J_n'(x)$ . Of length  $nt$ .
- n[l-1]** : ndarray  
Order of the  $J_n(x)$  or  $J_n'(x)$  associated with  $l$ th zero. Of length  $nt$ .

**m[l-1]** : ndarray  
Serial number of the zeros of  $J_n(x)$  or  $J_n'(x)$  associated with  $l$ th zero. Of length  $nt$ .

**t[l-1]** : ndarray  
0 if  $l$ th zero in  $z_0$  is zero of  $J_n(x)$ , 1 if it is a zero of  $J_n'(x)$ . Of length  $nt$ .

**See also:***jn\_zeros, jnp\_zeros***References***[R508]*`scipy.special.jnyn_zeros(n, nt)`Compute  $nt$  zeros of Bessel functions  $J_n(x)$ ,  $J_n'(x)$ ,  $Y_n(x)$ , and  $Y_n'(x)$ .Returns 4 arrays of length  $nt$ , corresponding to the first  $nt$  zeros of  $J_n(x)$ ,  $J_n'(x)$ ,  $Y_n(x)$ , and  $Y_n'(x)$ , respectively.

**Parameters**

**n** : int  
Order of the Bessel functions

**nt** : int  
Number ( $\leq 1200$ ) of zeros to compute

See **`jn_zeros`**, **`jnp_zeros`**, **`yn_zeros`**, **`ynp_zeros`** to get separate arrays.

**References***[R510]*`scipy.special.jn_zeros(n, nt)`Compute zeros of integer-order Bessel function  $J_n(x)$ .

**Parameters**

**n** : int  
Order of Bessel function

**nt** : int  
Number of zeros to return

**References***[R507]*`scipy.special.jnp_zeros(n, nt)`Compute zeros of integer-order Bessel function derivative  $J_n'(x)$ .

**Parameters**

**n** : int  
Order of Bessel function

**nt** : int  
Number of zeros to return

**References***[R509]*`scipy.special.yn_zeros(n, nt)`Compute zeros of integer-order Bessel function  $Y_n(x)$ .

**n** : int  
Order of Bessel function

**nt** : int  
Number of zeros to return

**References**

[R595]

`scipy.special.ynp_zeros` (*n*, *nt*)

Compute zeros of integer-order Bessel function derivative  $Y_n'(x)$ .

**Parameters**

- n** : int  
Order of Bessel function
- nt** : int  
Number of zeros to return

**References**

[R596]

`scipy.special.y0_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel function  $Y_0(z)$ , and derivative at each zero.

The derivatives are given by  $Y_0'(z_0) = -Y_1(z_0)$  at each zero  $z_0$ .

**Parameters**

- nt** : int  
Number of zeros to return
- complex** : bool, default False  
Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

**Returns**

- z0n** : ndarray  
Location of *n*th zero of  $Y_0(z)$
- y0pz0n** : ndarray  
Value of derivative  $Y_0'(z_0)$  for *n*th zero

**References**

[R590]

`scipy.special.y1_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel function  $Y_1(z)$ , and derivative at each zero.

The derivatives are given by  $Y_1'(z_1) = Y_0(z_1)$  at each zero  $z_1$ .

**Parameters**

- nt** : int  
Number of zeros to return
- complex** : bool, default False  
Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

**Returns**

- z1n** : ndarray  
Location of *n*th zero of  $Y_1(z)$
- y1pz1n** : ndarray  
Value of derivative  $Y_1'(z_1)$  for *n*th zero

**References**

[R592]

`scipy.special.y1p_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel derivative  $Y_1'(z)$ , and value at each zero.

The values are given by  $Y_1(z_1)$  at each  $z_1$  where  $Y_1'(z_1)=0$ .

**Parameters**

**nt** : int  
Number of zeros to return

**complex** : bool, default False  
Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

**Returns**

**z1pn** : ndarray  
Location of nth zero of  $Y_1'(z)$

**y1z1pn** : ndarray  
Value of derivative  $Y_1(z_1)$  for nth zero

**References**

[R593]

**Faster versions of common Bessel Functions**

$j_0(x)$	Bessel function of the first kind of order 0.
$j_1(x)$	Bessel function of the first kind of order 1.
$y_0(x)$	Bessel function of the second kind of order 0.
$y_1(x)$	Bessel function of the second kind of order 1.
$i_0(x)$	Modified Bessel function of order 0.
$i_0e(x)$	Exponentially scaled modified Bessel function of order 0.
$i_1(x)$	Modified Bessel function of order 1.
$i_1e(x)$	Exponentially scaled modified Bessel function of order 1.
$k_0(x)$	Modified Bessel function of the second kind of order 0, $K_0$ .
$k_0e(x)$	Exponentially scaled modified Bessel function K of order 0
$k_1(x)$	Modified Bessel function of the second kind of order 1, $K_1(x)$ .
$k_1e(x)$	Exponentially scaled modified Bessel function K of order 1

`scipy.special.j0(x) = <ufunc 'j0'>`  
Bessel function of the first kind of order 0.

**Parameters** **x** : array\_like  
Argument (float).

**Returns** **J** : ndarray  
Value of the Bessel function of the first kind of order 0 at x.

**See also:****jv** Bessel function of real order and complex argument.**spherical\_jn**  
spherical Bessel functions.**Notes**

The domain is divided into the intervals  $[0, 5]$  and  $(5, \text{infinity})$ . In the first interval the following rational approximation is used:

$$J_0(x) \approx (w - r_1^2)(w - r_2^2) \frac{P_3(w)}{Q_8(w)},$$

where  $w = x^2$  and  $r_1, r_2$  are the zeros of  $J_0$ , and  $P_3$  and  $Q_8$  are polynomials of degrees 3 and 8, respectively.

**References***[R589]*

`scipy.special.y1(x) = <ufunc 'y1'>`  
 Bessel function of the second kind of order 1.

**Parameters** `x` : array\_like  
 Argument (float).  
**Returns** `Y` : ndarray  
 Value of the Bessel function of the second kind of order 1 at  $x$ .

**See also:***j1, yn, yv***Notes**

The domain is divided into the intervals  $[0, 8]$  and  $(8, \text{infinity})$ . In the first interval a 25 term Chebyshev expansion is used, and computing  $J_1$  (the Bessel function of the first kind) is required. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes *[R591]* routine *y1*.

**References***[R591]*

`scipy.special.i0(x) = <ufunc 'i0'>`  
 Modified Bessel function of order 0.

Defined as,

$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2} = J_0(ix),$$

where  $J_0$  is the Bessel function of the first kind of order 0.

**Parameters** `x` : array\_like  
 Argument (float)  
**Returns** `I` : ndarray  
 Value of the modified Bessel function of order 0 at  $x$ .

**See also:***iv, i0e***Notes**

The range is partitioned into the two intervals  $[0, 8]$  and  $(8, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes *[R491]* routine *i0*.

**References***[R491]*

`scipy.special.i0e(x) = <ufunc 'i0e'>`  
 Exponentially scaled modified Bessel function of order 0.

Defined as:

$$i0e(x) = \exp(-\text{abs}(x)) * i0(x).$$

**Parameters** `x` : array\_like  
**Returns** `I` : ndarray     Argument (float)  
Value of the exponentially scaled modified Bessel function of order 0 at  $x$ .

**See also:**

`iv`, `i0`

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in `i0`, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephys [R492] routine `i0e`.

**References**

[R492]

`scipy.special.i1(x) = <ufunc 'i1'>`

Modified Bessel function of order 1.

Defined as,

$$I_1(x) = \frac{1}{2}x \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{k!(k+1)!} = -iJ_1(ix),$$

where  $J_1$  is the Bessel function of the first kind of order 1.

**Parameters** `x` : array\_like  
**Returns** `I` : ndarray     Argument (float)  
Value of the modified Bessel function of order 1 at  $x$ .

**See also:**

`iv`, `ile`

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [R493] routine `i1`.

**References**

[R493]

`scipy.special.ile(x) = <ufunc 'ile'>`

Exponentially scaled modified Bessel function of order 1.

Defined as:

$$ile(x) = \exp(-abs(x)) * i1(x)$$

**Parameters** `x` : array\_like  
**Returns** `I` : ndarray     Argument (float)  
Value of the exponentially scaled modified Bessel function of order 1 at  $x$ .

**See also:***iv, i1***Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in *i1*, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephys [R494] routine *i1e*.

**References***[R494]*

`scipy.special.k0(x) = <ufunc 'k0'>`

Modified Bessel function of the second kind of order 0,  $K_0$ .

This function is also sometimes referred to as the modified Bessel function of the third kind of order 0.

**Parameters** **x** : array\_like  
Argument (float).

**Returns** **K** : ndarray  
Value of the modified Bessel function  $K_0$  at  $x$ .

**See also:***kv, k0e***Notes**

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [R515] routine *k0*.

**References***[R515]*

`scipy.special.k0e(x) = <ufunc 'k0e'>`

Exponentially scaled modified Bessel function K of order 0

Defined as:

$$k0e(x) = \exp(x) * k0(x).$$

**Parameters** **x** : array\_like  
Argument (float)

**Returns** **K** : ndarray  
Value of the exponentially scaled modified Bessel function K of order 0 at  $x$ .

**See also:***kv, k0***Notes**

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [R516] routine *k0e*.

**References**

[R516]

`scipy.special.k1(x) = <ufunc 'k1'>`

Modified Bessel function of the second kind of order 1,  $K_1(x)$ .

**Parameters** `x` : array\_like  
**Returns** `K` : ndarray

Argument (float)  
 Value of the modified Bessel function K of order 1 at  $x$ .

**See also:**

`kv`, `k1e`

**Notes**

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [R517] routine `k1`.

**References**

[R517]

`scipy.special.k1e(x) = <ufunc 'k1e'>`

Exponentially scaled modified Bessel function K of order 1

Defined as:

$k1e(x) = \exp(x) * k1(x)$
----------------------------

**Parameters** `x` : array\_like  
**Returns** `K` : ndarray

Argument (float)  
 Value of the exponentially scaled modified Bessel function K of order 1 at  $x$ .

**See also:**

`kv`, `k1`

**Notes**

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [R518] routine `k1e`.

where  $J_\nu$  is a Bessel function and  $\lambda = lmb$ ,  $\nu = nu$ .

### Derivatives of Bessel Functions

<code>jvp(v, z[, n])</code>	Compute nth derivative of Bessel function $J_\nu(z)$ with respect to $z$ .
<code>yvp(v, z[, n])</code>	Compute nth derivative of Bessel function $Y_\nu(z)$ with respect to $z$ .
<code>kvp(v, z[, n])</code>	Compute nth derivative of real-order modified Bessel function $K_\nu(z)$
<code>ivp(v, z[, n])</code>	Compute nth derivative of modified Bessel function $I_\nu(z)$ with respect to $z$ .
<code>h1vp(v, z[, n])</code>	Compute nth derivative of Hankel function $H_{1\nu}(z)$ with respect to $z$ .
<code>h2vp(v, z[, n])</code>	Compute nth derivative of Hankel function $H_{2\nu}(z)$ with respect to $z$ .

`scipy.special.jvp(v, z, n=1)`

Compute nth derivative of Bessel function  $J_\nu(z)$  with respect to  $z$ .

**Parameters**

- v** : float  
Order of Bessel function
- z** : complex  
Argument at which to evaluate the derivative
- n** : int, default 1  
Order of derivative

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [R514].

**References**

[R513], [R514]

`scipy.special.yvp(v, z, n=1)`

Compute nth derivative of Bessel function  $Y_v(z)$  with respect to  $z$ .

**Parameters**

- v** : float  
Order of Bessel function
- z** : complex  
Argument at which to evaluate the derivative
- n** : int, default 1  
Order of derivative

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [R600].

**References**

[R599], [R600]

`scipy.special.kvp(v, z, n=1)`

Compute nth derivative of real-order modified Bessel function  $K_v(z)$

$K_v(z)$  is the modified Bessel function of the second kind. Derivative is calculated with respect to  $z$ .

**Parameters**

- v** : array\_like of float  
Order of Bessel function
- z** : array\_like of complex  
Argument at which to evaluate the derivative
- n** : int  
Order of derivative. Default is first derivative.

**Returns**

- out** : ndarray  
The results

**Notes**

The derivative is computed using the relation DLFM 10.29.5 [R531].

**References**

[R530], [R531]

**Examples**

Calculate multiple values at order 5:

```
>>> from scipy.special import kvp
>>> kvp(5, (1, 2, 3+5j))
array([-1849.0354+0.j      , -25.7735+0.j      , -0.0307+0.0875j])
```

Calculate for a single value at multiple orders:

```
>>> kvp((4, 4.5, 5), 1)
array([-184.0309, -568.9585, -1849.0354])
```

`scipy.special.ivp(v, z, n=1)`

Compute nth derivative of modified Bessel function  $I_v(z)$  with respect to  $z$ .

**Parameters**

- v** : array\_like of float  
Order of Bessel function
- z** : array\_like of complex  
Argument at which to evaluate the derivative
- n** : int, default 1  
Order of derivative

#### Notes

The derivative is computed using the relation DLFM 10.29.5 [R503].

#### References

[R502], [R503]

`scipy.special.h1vp(v, z, n=1)`

Compute nth derivative of Hankel function  $H_1v(z)$  with respect to  $z$ .

**Parameters**

- v** : float  
Order of Hankel function
- z** : complex  
Argument at which to evaluate the derivative
- n** : int, default 1  
Order of derivative

#### Notes

The derivative is computed using the relation DLFM 10.6.7 [R481].

#### References

[R480], [R481]

`scipy.special.h2vp(v, z, n=1)`

Compute nth derivative of Hankel function  $H_2v(z)$  with respect to  $z$ .

**Parameters**

- v** : float  
Order of Hankel function
- z** : complex  
Argument at which to evaluate the derivative
- n** : int, default 1  
Order of derivative

#### Notes

The derivative is computed using the relation DLFM 10.6.7 [R483].

**References**

[R482], [R483]

**Spherical Bessel Functions**

<code>spherical_jn(n, z[, derivative])</code>	Spherical Bessel function of the first kind or its derivative.
<code>spherical_yn(n, z[, derivative])</code>	Spherical Bessel function of the second kind or its derivative.
<code>spherical_in(n, z[, derivative])</code>	Modified spherical Bessel function of the first kind or its derivative.
<code>spherical_kn(n, z[, derivative])</code>	Modified spherical Bessel function of the second kind or its derivative.

`scipy.special.spherical_jn(n, z, derivative=False)`

Spherical Bessel function of the first kind or its derivative.

Defined as [R578],

$$j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z),$$

where  $J_n$  is the Bessel function of the first kind.

**Parameters** `n` : int, array\_like

Order of the Bessel function ( $n \geq 0$ ).

`z` : complex or float, array\_like

Argument of the Bessel function.

**derivative** : bool, optional

If True, the value of the derivative (rather than the function itself) is returned.

**Returns** `jn` : ndarray

**Notes**

For real arguments greater than the order, the function is computed using the ascending recurrence [R579]. For small real or complex arguments, the definitional relation to the cylindrical Bessel function of the first kind is used.

The derivative is computed using the relations [R580],

$$j'_n(z) = j_{n-1}(z) - \frac{n+1}{z} j_n(z).$$

$$j'_0(z) = -j_1(z)$$

New in version 0.18.0.

**References**

[R578], [R579], [R580]

`scipy.special.spherical_yn(n, z, derivative=False)`

Spherical Bessel function of the second kind or its derivative.

Defined as [R583],

$$y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z),$$

where  $Y_n$  is the Bessel function of the second kind.

**Parameters** **n** : int, array\_like  
Order of the Bessel function ( $n \geq 0$ ).  
**z** : complex or float, array\_like  
Argument of the Bessel function.  
**derivative** : bool, optional  
If True, the value of the derivative (rather than the function itself) is returned.

**Returns** **yn** : ndarray

**Notes**

For real arguments, the function is computed using the ascending recurrence [R584]. For complex arguments, the definitional relation to the cylindrical Bessel function of the second kind is used.

The derivative is computed using the relations [R585],

$$y'_n = y_{n-1} - \frac{n+1}{2} y_n.$$

$$y'_0 = -y_1$$

New in version 0.18.0.

**References**

[R583], [R584], [R585]

`scipy.special.spherical_in` ( $n, z, derivative=False$ )  
Modified spherical Bessel function of the first kind or its derivative.

Defined as [R576],

$$i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+1/2}(z),$$

where  $I_n$  is the modified Bessel function of the first kind.

**Parameters** **n** : int, array\_like  
Order of the Bessel function ( $n \geq 0$ ).  
**z** : complex or float, array\_like  
Argument of the Bessel function.  
**derivative** : bool, optional  
If True, the value of the derivative (rather than the function itself) is returned.

**Returns** **in** : ndarray

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the first kind.

The derivative is computed using the relations [R577],

$$i'_n = i_{n-1} - \frac{n+1}{2} i_n.$$

$$i'_1 = i_0$$

New in version 0.18.0.

**References**

[R576], [R577]

`scipy.special.spherical_yn` (*n*, *z*, *derivative=False*)

Modified spherical Bessel function of the second kind or its derivative.

Defined as [R581],

$$k_n(z) = \sqrt{\frac{\pi}{2z}} K_{n+1/2}(z),$$

where  $K_n$  is the modified Bessel function of the second kind.

**Parameters**

- n** : int, array\_like  
Order of the Bessel function ( $n \geq 0$ ).
- z** : complex or float, array\_like  
Argument of the Bessel function.
- derivative** : bool, optional  
If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- kn** : ndarray

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the second kind.

The derivative is computed using the relations [R582],

$$k'_n = -k_{n-1} - \frac{n+1}{2} k_n.$$

$$k'_0 = -k_1$$

New in version 0.18.0.

**References**

[R581], [R582]

**Riccati-Bessel Functions**

These are not universal functions:

<code>riccati_jn</code> ( <i>n</i> , <i>x</i> )	Compute Riccati-Bessel function of the first kind and its derivative.
<code>riccati_yn</code> ( <i>n</i> , <i>x</i> )	Compute Riccati-Bessel function of the second kind and its derivative.

`scipy.special.riccati_jn` (*n*, *x*)

Compute Riccati-Bessel function of the first kind and its derivative.

The Riccati-Bessel function of the first kind is defined as  $xj_n(x)$ , where  $j_n$  is the spherical Bessel function of the first kind of order  $n$ .

This function computes the value and first derivative of the Riccati-Bessel function for all orders up to and including  $n$ .

**Parameters**

- n** : int  
Maximum order of function to compute
- x** : float

**Returns**

**jn** : ndarray     Argument at which to evaluate  
                          Value of  $j_0(x), \dots, j_n(x)$

**jnp** : ndarray  
                          First derivative  $j_0'(x), \dots, j_n'(x)$

**Notes**

The computation is carried out via backward recurrence, using the relation DLMF 10.51.1 [R565].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R564].

**References**

[R564], [R565]

`scipy.special.riccati_yn` ( $n, x$ )

Compute Riccati-Bessel function of the second kind and its derivative.

The Riccati-Bessel function of the second kind is defined as  $xy_n(x)$ , where  $y_n$  is the spherical Bessel function of the second kind of order  $n$ .

This function computes the value and first derivative of the function for all orders up to and including  $n$ .

**Parameters**

**n** : int  
                          Maximum order of function to compute

**x** : float

**Returns**

**yn** : ndarray     Argument at which to evaluate  
                          Value of  $y_0(x), \dots, y_n(x)$

**ynp** : ndarray  
                          First derivative  $y_0'(x), \dots, y_n'(x)$

**Notes**

The computation is carried out via ascending recurrence, using the relation DLMF 10.51.1 [R567].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R566].

**References**

[R566], [R567]

**Struve Functions**

<code>struve</code> ( $v, x$ )	Struve function.
<code>modstruve</code> ( $v, x$ )	Modified Struve function.
<code>itstruve0</code> ( $x$ )	Integral of the Struve function of order 0.
<code>it2struve0</code> ( $x$ )	Integral related to the Struve function of order 0.
<code>itmodstruve0</code> ( $x$ )	Integral of the modified Struve function of order 0.

`scipy.special.struve` ( $v, x$ ) = <ufunc 'struve'>

Struve function.

Return the value of the Struve function of order  $v$  at  $x$ . The Struve function is defined as,

$$H_v(x) = (z/2)^{v+1} \sum_{n=0}^{\infty} \frac{(-1)^n (z/2)^{2n}}{\Gamma(n + \frac{3}{2})\Gamma(n + v + \frac{3}{2})},$$

where  $\Gamma$  is the gamma function.

**Parameters** **v** : array\_like  
 Order of the Struve function (float).  
**x** : array\_like  
 Argument of the Struve function (float; must be positive unless  $v$  is an integer).  
**Returns** **H** : ndarray  
 Value of the Struve function of order  $v$  at  $x$ .

**See also:**

`modstruve`

**Notes**

Three methods discussed in [R586] are used to evaluate the Struve function:

- power series
- expansion in Bessel functions (if  $|z| < |v| + 20$ )
- asymptotic large- $z$  expansion (if  $z \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

**References**

[R586]

`scipy.special.modstruve` ( $v, x$ ) = <ufunc 'modstruve'>

Modified Struve function.

Return the value of the modified Struve function of order  $v$  at  $x$ . The modified Struve function is defined as,

$$L_v(x) = -i \exp(-\pi v/2) H_v(x),$$

where  $H_v$  is the Struve function.

**Parameters** **v** : array\_like  
 Order of the modified Struve function (float).  
**x** : array\_like  
 Argument of the Struve function (float; must be positive unless  $v$  is an integer).  
**Returns** **L** : ndarray  
 Value of the modified Struve function of order  $v$  at  $x$ .

**See also:**

`struve`

**Notes**

Three methods discussed in [R545] are used to evaluate the function:

- power series
- expansion in Bessel functions (if  $|z| < |v| + 20$ )
- asymptotic large- $z$  expansion (if  $z \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

**References**

[R545]

`scipy.special.itstruve0(x) = <ufunc 'itstruve0'>`

Integral of the Struve function of order 0.

$$I = \int_0^x H_0(t) dt$$

**Parameters** `x` : array\_like  
**Returns** `I` : ndarray      Upper limit of integration (float).  
 The integral of  $H_0$  from 0 to  $x$ .

**See also:**

`struve`

**Notes**

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R498].

**References**

[R498]

`scipy.special.it2struve0(x) = <ufunc 'it2struve0'>`

Integral related to the Struve function of order 0.

Returns the integral,

$$\int_x^\infty \frac{H_0(t)}{t} dt$$

where  $H_0$  is the Struve function of order 0.

**Parameters** `x` : array\_like  
**Returns** `I` : ndarray      Lower limit of integration.  
 The value of the integral.

**See also:**

`struve`

**Notes**

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R495].

**References**

[R495]

`scipy.special.itmodstruve0(x) = <ufunc 'itmodstruve0'>`

Integral of the modified Struve function of order 0.

$$I = \int_0^x L_0(t) dt$$

**Parameters** `x` : array\_like  
**Returns** `I` : ndarray      Upper limit of integration (float).  
 The integral of  $L_0$  from 0 to  $x$ .

**Notes**

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R497].

<code>inv_boxcox1p(y, lmbda)</code>	Compute the inverse of the Box-Cox transformation.

`scipy.special.bdtr(k, n, p) = <ufunc 'bdtr'>`

Binomial distribution cumulative distribution function.

Sum of the terms 0 through  $k$  of the Binomial probability density.

$$\text{bdtr}(k, n, p) = \sum_{j=0}^k \binom{n}{j} p^j (1-p)^{n-j}$$

**Parameters** `k` : array\_like

Number of successes (int).

`n` : array\_like

Number of events (int).

`p` : array\_like

Probability of success in a single event (float).

**Returns** `y` : ndarray

Probability of  $k$  or fewer successes in  $n$  independent events with success probabilities of  $p$ .

**Notes**

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtr}(k, n, p) = I_{1-p}(n - k, k + 1).$$

Wrapper for the Cephes [R416] routine *bdt r*.

**References**

[R416]

`scipy.special.bdt rc(k, n, p) = <ufunc 'bdt rc'>`

Binomial distribution survival function.

Sum of the terms  $k + 1$  through  $n$  of the binomial probability density,

$$\text{bdtrc}(k, n, p) = \sum_{j=k+1}^n \binom{n}{j} p^j (1 - p)^{n-j}$$

<b>Parameters</b>	<b>k</b> : array_like Number of successes (int).
	<b>n</b> : array_like Number of events (int)
	<b>p</b> : array_like Probability of success in a single event.
<b>Returns</b>	<b>y</b> : ndarray Probability of $k + 1$ or more successes in $n$ independent events with success probabilities of $p$ .

**See also:**

*bdt r*, *betainc*

**Notes**

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtrc}(k, n, p) = I_p(k + 1, n - k).$$

Wrapper for the Cephes [R417] routine *bdt rc*.

**References**

[R417]

`scipy.special.bdt ri(k, n, y) = <ufunc 'bdt ri'>`

Inverse function to *bdt r* with respect to  $p$ .

Finds the event probability  $p$  such that the sum of the terms 0 through  $k$  of the binomial probability density is equal to the given cumulative probability  $y$ .

<b>Parameters</b>	<b>k</b> : array_like Number of successes (float).
	<b>n</b> : array_like Number of events (float)
	<b>y</b> : array_like Cumulative probability (probability of $k$ or fewer successes in $n$ events).
<b>Returns</b>	<b>p</b> : ndarray

The event probability such that  $bdtr(k, n, p) = y$ .

**See also:**

`bdtr`, `betaincinv`

**Notes**

The computation is carried out using the inverse beta integral function and the relation,:

$$1 - p = \text{betaincinv}(n - k, k + 1, y).$$

Wrapper for the Cephes [R418] routine `bdtri`.

**References**

[R418]

`scipy.special.bdtrik`( $y, n, p$ ) = <ufunc 'bdtrik'>

Inverse function to `bdtr` with respect to  $k$ .

Finds the number of successes  $k$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for  $n$  events with probability  $p$  is equal to the given cumulative probability  $y$ .

**Parameters**

- y** : array\_like  
Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).
- n** : array\_like  
Number of events (float).
- p** : array\_like  
Success probability (float).

**Returns**

- k** : ndarray  
The number of successes  $k$  such that  $bdtr(k, n, p) = y$ .

**See also:**

`bdtr`

**Notes**

Formula 26.5.24 of [R419] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

Wrapper for the CDFLIB [R420] Fortran routine `cdfbin`.

**References**

[R419], [R420]

`scipy.special.bdtrin`( $k, y, p$ ) = <ufunc 'bdtrin'>

Inverse function to `bdtr` with respect to  $n$ .

Finds the number of events  $n$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for events with probability  $p$  is equal to the given cumulative probability  $y$ .

**Parameters**

- k** : array\_like  
Number of successes (float).
- y** : array\_like  
Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).
- p** : array\_like  
Success probability (float).

**Returns**

- n** : ndarray

The number of events  $n$  such that  $bctr(k, n, p) = y$ .

**See also:**

`bctr`

**Notes**

Formula 26.5.24 of [R421] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $n$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $n$ .

Wrapper for the CDFLIB [R422] Fortran routine `cdfbin`.

**References**

[R421], [R422]

`scipy.special.bctdtr(a, b, x) = <ufunc 'bctdtr'>`

Cumulative density function of the beta distribution.

Returns the integral from zero to  $x$  of the beta probability density function,

$$I = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

where  $\Gamma$  is the gamma function.

<b>Parameters</b>	<b>a</b> : array_like	Shape parameter ( $a > 0$ ).
	<b>b</b> : array_like	Shape parameter ( $b > 0$ ).
	<b>x</b> : array_like	Upper limit of integration, in $[0, 1]$ .
<b>Returns</b>	<b>I</b> : ndarray	Cumulative density function of the beta distribution with parameters $a$ and $b$ at $x$ .

**See also:**

`betainc`

**Notes**

This function is identical to the incomplete beta integral function `betainc`.

Wrapper for the Cephes [R429] routine `bctdtr`.

**References**

[R429]

`scipy.special.bctdtri(a, b, p) = <ufunc 'bctdtri'>`

The  $p$ -th quantile of the beta distribution.

This function is the inverse of the beta cumulative distribution function, `bctdtr`, returning the value of  $x$  for which `bctdtr(a, b, x) = p`, or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters** **a** : array\_like

**Returns**     **b** : array\_like     Shape parameter ( $a > 0$ ).  
                  **p** : array\_like     Shape parameter ( $b > 0$ ).  
                  **x** : ndarray       Cumulative probability, in  $[0, 1]$ .  
                                          The quantile corresponding to  $p$ .

**See also:**

*betaincinv*, *btdtr*

**Notes**

The value of  $x$  is found by interval halving or Newton iterations.

Wrapper for the Cephes [R430] routine *incbi*, which solves the equivalent problem of finding the inverse of the incomplete beta integral.

**References**

[R430]

`scipy.special.btdtria` ( $p, b, x$ ) = <ufunc 'btdtria'>  
Inverse of *btdtr* with respect to  $a$ .

This is the inverse of the beta cumulative distribution function, *btdtr*, considered as a function of  $a$ , returning the value of  $a$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters**   **p** : array\_like     Cumulative probability, in  $[0, 1]$ .  
                  **b** : array\_like     Shape parameter ( $b > 0$ ).  
                  **x** : array\_like     The quantile, in  $[0, 1]$ .  
**Returns**       **a** : ndarray             The value of the shape parameter  $a$  such that  $btdtr(a, b, x) = p$ .

**See also:**

**btdtr**           Cumulative density function of the beta distribution.  
**btdtri**          Inverse with respect to  $x$ .  
**btdtrib**        Inverse with respect to  $b$ .

**Notes**

Wrapper for the CDFLIB [R431] Fortran routine *cdfbet*.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [R432]. Computation of  $a$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $a$ .

**References**

[R431], [R432]

`scipy.special.btdtrib` ( $a, p, x$ ) = <ufunc 'btdtrib'>  
Inverse of *btdtr* with respect to  $b$ .

This is the inverse of the beta cumulative distribution function, `btctr`, considered as a function of  $b$ , returning the value of  $b$  for which  $btctr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters**

- a** : array\_like  
Shape parameter ( $a > 0$ ).
- p** : array\_like  
Cumulative probability, in  $[0, 1]$ .
- x** : array\_like  
The quantile, in  $[0, 1]$ .

**Returns**

- b** : ndarray  
The value of the shape parameter  $b$  such that  $btctr(a, b, x) = p$ .

**See also:**

**btctr** Cumulative density function of the beta distribution.  
**btctri** Inverse with respect to  $x$ .  
**btctria** Inverse with respect to  $a$ .

**Notes**

Wrapper for the CDFLIB [R433] Fortran routine `cdfbet`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [R434]. Computation of  $b$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $b$ .

**References**

[R433], [R434]

`scipy.special.fctrf` ( $dfn, dfd, x$ ) = <ufunc 'fctrf'>  
 F cumulative distribution function.

Returns the value of the cumulative density function of the F-distribution, also known as Snedecor's F-distribution or the Fisher-Snedecor distribution.

The F-distribution with parameters  $d_n$  and  $d_d$  is the distribution of the random variable,

$$X = \frac{U_n/d_n}{U_d/d_d},$$

where  $U_n$  and  $U_d$  are random variables distributed  $\chi^2$ , with  $d_n$  and  $d_d$  degrees of freedom, respectively.

**Parameters**

- dfn** : array\_like  
First parameter (positive float).
- dfd** : array\_like  
Second parameter (positive float).
- x** : array\_like  
Argument (nonnegative float).

**Returns**

- y** : ndarray  
The CDF of the F-distribution with parameters  $dfn$  and  $dfd$  at  $x$ .

**Notes**

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{x d_n / (d_d + x d_n)}(d_n/2, d_d/2).$$

Wrapper for the Cephes [R464] routine `fctrf`.

**References**

[R464]

`scipy.special.fdtrc` (*dfn*, *dfd*, *x*) = <ufunc 'fdtrc'>

F survival function.

Returns the complemented F-distribution function (the integral of the density from *x* to infinity).

**Parameters**

- dfn** : array\_like  
First parameter (positive float).
- dfd** : array\_like  
Second parameter (positive float).
- x** : array\_like  
Argument (nonnegative float).

**Returns**

- y** : ndarray  
The complemented F-distribution function with parameters *dfn* and *dfd* at *x*.

**See also:***fdtr***Notes**

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{d_d/(d_d+x d_n)}(d_d/2, d_n/2).$$

Wrapper for the Cephes [R465] routine *fdtrc*.**References**

[R465]

`scipy.special.fdttri` (*dfn*, *dfd*, *p*) = <ufunc 'fdtri'>The *p*-th quantile of the F-distribution.This function is the inverse of the F-distribution CDF, *fdtr*, returning the *x* such that *fdtr*(*dfn*, *dfd*, *x*) = *p*.

**Parameters**

- dfn** : array\_like  
First parameter (positive float).
- dfd** : array\_like  
Second parameter (positive float).
- p** : array\_like  
Cumulative probability, in [0, 1].

**Returns**

- x** : ndarray  
The quantile corresponding to *p*.

**Notes**The computation is carried out using the relation to the inverse regularized beta function,  $I_x^{-1}(a, b)$ . Let  $z = I_p^{-1}(d_d/2, d_n/2)$ . Then,

$$x = \frac{d_d(1-z)}{d_n z}.$$

If *p* is such that  $x < 0.5$ , the following relation is used instead for improved stability: let  $z' = I_{1-p}^{-1}(d_n/2, d_d/2)$ . Then,

$$x = \frac{d_d z'}{d_n(1-z')}.$$

Wrapper for the Cephes [R466] routine *fdtri*.

**References**

[R466]

`scipy.special.fdtroidfd(dfn, p, x) = <ufunc 'fdtridf'>`

Inverse to `fdtr` vs `dfd`

Finds the F density argument `dfd` such that `fdtr(dfn, dfd, x) == p`.

`scipy.special.gdtr(a, b, x) = <ufunc 'gdtr'>`

Gamma distribution cumulative density function.

Returns the integral from zero to  $x$  of the gamma probability density function,

$$F = \int_0^x \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

**Parameters** **a** : array\_like

The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .

**b** : array\_like

The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).

**x** : array\_like

The quantile (upper limit of integration; float).

**Returns** **F** : ndarray

The CDF of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

**See also:**

**gdtrc** 1 - CDF of the gamma distribution.

**Notes**

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

Wrapper for the Cephes [R472] routine `gdtr`.

**References**

[R472]

`scipy.special.gdtrc(a, b, x) = <ufunc 'gdtrc'>`

Gamma distribution survival function.

Integral from  $x$  to infinity of the gamma probability density function,

$$F = \int_x^\infty \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

**Parameters** **a** : array\_like

The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .

**b** : array\_like

The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).

**x** : array\_like

The quantile (lower limit of integration; float).

**Returns** **F** : ndarray

The survival function of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

**See also:**

`gdftr`, `gdftri`

**Notes**

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function). Wrapper for the Cephes [R473] routine `gdftrc`.

**References**

[R473]

`scipy.special.gdftria` ( $p, b, x, out=None$ ) = <ufunc 'gdftria'>

Inverse of `gdftr` vs  $a$ .

Returns the inverse with respect to the parameter  $a$  of  $p = \text{gdftr}(a, b, x)$ , the cumulative distribution function of the gamma distribution.

<b>Parameters</b>	<b>p</b> : array_like	Probability values.
	<b>b</b> : array_like	$b$ parameter values of $\text{gdftr}(a, b, x)$ . $b$ is the “shape” parameter of the gamma distribution.
	<b>x</b> : array_like	Nonnegative real values, from the domain of the gamma distribution.
	<b>out</b> : ndarray, optional	If a fourth argument is given, it must be a <code>numpy.ndarray</code> whose size matches the broadcast result of $a$ , $b$ and $x$ . <code>out</code> is then the array returned by the function.
<b>Returns</b>	<b>a</b> : ndarray	Values of the $a$ parameter such that $p = \text{gdftr}(a, b, x)$ . $1/a$ is the “scale” parameter of the gamma distribution.

**See also:**

<b>gdftr</b>	CDF of the gamma distribution.
<b>gdftrib</b>	Inverse with respect to $b$ of $\text{gdftr}(a, b, x)$ .
<b>gdftrix</b>	Inverse with respect to $x$ of $\text{gdftr}(a, b, x)$ .

**Notes**

Wrapper for the CDFLIB [R474] Fortran routine `cdfgam`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [R475]. Computation of  $a$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $a$ .

**References**

[R474], [R475]

**Examples**

First evaluate `gdftr`.

```
>>> from scipy.special import gdftr, gdftria
>>> p = gdftr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdftria(p, 3.4, 5.6)
1.2
```

`scipy.special.gdftrib(a, p, x, out=None) = <ufunc 'gdftrib'>`

Inverse of `gdftr` vs `b`.

Returns the inverse with respect to the parameter `b` of `p = gdftr(a, b, x)`, the cumulative distribution function of the gamma distribution.

**Parameters**

- a** : array\_like  
`a` parameter values of `gdftr(a, b, x)`. `1/a` is the “scale” parameter of the gamma distribution.
- p** : array\_like  
Probability values.
- x** : array\_like  
Nonnegative real values, from the domain of the gamma distribution.
- out** : ndarray, optional  
If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of `a`, `b` and `x`. `out` is then the array returned by the function.

**Returns**

- b** : ndarray  
Values of the `b` parameter such that `p = gdftr(a, b, x)`. `b` is the “shape” parameter of the gamma distribution.

**See also:**

**gdftr** CDF of the gamma distribution.  
**gdftria** Inverse with respect to `a` of `gdftr(a, b, x)`.  
**gdftrix** Inverse with respect to `x` of `gdftr(a, b, x)`.

**Notes**

Wrapper for the CDFLIB [R476] Fortran routine `cdfgam`.

The cumulative distribution function `p` is computed using a routine by DiDinato and Morris [R477]. Computation of `b` involves a search for a value that produces the desired value of `p`. The search relies on the monotonicity of `p` with `b`.

**References**

[R476], [R477]

**Examples**

First evaluate `gdftr`.

```
>>> from scipy.special import gdftr, gdftrib
>>> p = gdftr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtrib(1.2, p, 5.6)
3.3999999999723882
```

`scipy.special.gdtrix(a, b, p, out=None) = <ufunc 'gdtrix'>`

Inverse of `gdtr` vs `x`.

Returns the inverse with respect to the parameter `x` of  $p = \text{gdtr}(a, b, x)$ , the cumulative distribution function of the gamma distribution. This is also known as the  $p$ 'th quantile of the distribution.

**Parameters**

- a** : array\_like  
*a* parameter values of  $\text{gdtr}(a, b, x)$ .  $1/a$  is the “scale” parameter of the gamma distribution.
- b** : array\_like  
*b* parameter values of  $\text{gdtr}(a, b, x)$ . *b* is the “shape” parameter of the gamma distribution.
- p** : array\_like  
Probability values.
- out** : ndarray, optional  
If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of *a*, *b* and *x*. *out* is then the array returned by the function.

**Returns**

- x** : ndarray  
Values of the *x* parameter such that  $p = \text{gdtr}(a, b, x)$ .

**See also:**

**gdtr** CDF of the gamma distribution.  
**gdtria** Inverse with respect to *a* of  $\text{gdtr}(a, b, x)$ .  
**gdtrib** Inverse with respect to *b* of  $\text{gdtr}(a, b, x)$ .

**Notes**

Wrapper for the CDFLIB [R478] Fortran routine `cdfgam`.

The cumulative distribution function *p* is computed using a routine by DiDinato and Morris [R479]. Computation of *x* involves a search for a value that produces the desired value of *p*. The search relies on the monotonicity of *p* with *x*.

**References**

[R478], [R479]

**Examples**

First evaluate `gdtr`.

```
>>> from scipy.special import gdtr, gdtrix
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtrix(1.2, 3.4, p)
5.5999999999999996
```

`scipy.special.nbdtr(k, n, p) = <ufunc 'nbdtr'>`

Negative binomial cumulative distribution function.

Returns the sum of the terms 0 through  $k$  of the negative binomial distribution probability mass function,

$$F = \sum_{j=0}^k \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities  $p$ , this is the probability that  $k$  or fewer failures precede the  $n$ th success.

**Parameters**

- k** : array\_like  
The maximum number of allowed failures (nonnegative int).
- n** : array\_like  
The target number of successes (positive int).
- p** : array\_like  
Probability of success in a single event (float).

**Returns**

- F** : ndarray  
The probability of  $k$  or fewer failures before  $n$  successes in a sequence of events with individual success probability  $p$ .

**See also:**

`nbdtrc`

**Notes**

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdtr}(k, n, p) = I_p(n, k + 1).$$

Wrapper for the Cephes [R546] routine `nbdtr`.

**References**

[R546]

`scipy.special.nbdtrc(k, n, p) = <ufunc 'nbdtrc'>`

Negative binomial survival function.

Returns the sum of the terms  $k + 1$  to infinity of the negative binomial distribution probability mass function,

$$F = \sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities  $p$ , this is the probability that more than  $k$  failures precede the  $n$ th success.

**Parameters**

- k** : array\_like  
The maximum number of allowed failures (nonnegative int).
- n** : array\_like  
The target number of successes (positive int).
- p** : array\_like  
Probability of success in a single event (float).

**Returns**

- F** : ndarray  
The probability of  $k + 1$  or more failures before  $n$  successes in a sequence of events with individual success probability  $p$ .

**Notes**

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdtrc}(k, n, p) = I_{1-p}(k + 1, n).$$

Wrapper for the Cephes [R547] routine *nbdtrc*.

**References**

[R547]

`scipy.special.nbdtri`( $k, n, y$ ) = <ufunc 'nbdtri'>  
Inverse of *nbdt r* vs  $p$ .

Returns the inverse with respect to the parameter  $p$  of  $y = \text{nbdt r}(k, n, p)$ , the negative binomial cumulative distribution function.

<b>Parameters</b>	<b>k</b> : array_like	The maximum number of allowed failures (nonnegative int).
	<b>n</b> : array_like	The target number of successes (positive int).
	<b>y</b> : array_like	The probability of $k$ or fewer failures before $n$ successes (float).
<b>Returns</b>	<b>p</b> : ndarray	Probability of success in a single event (float) such that $\text{nbdt r}(k, n, p) = y$ .

**See also:**

**nbdt r** Cumulative distribution function of the negative binomial.  
**nbdt rik** Inverse with respect to  $k$  of  $\text{nbdt r}(k, n, p)$ .  
**nbdt rin** Inverse with respect to  $n$  of  $\text{nbdt r}(k, n, p)$ .

**Notes**

Wrapper for the Cephes [R548] routine *nbdt ri*.

**References**

[R548]

`scipy.special.nbdtrik`( $y, n, p$ ) = <ufunc 'nbdtrik'>  
Inverse of *nbdt r* vs  $k$ .

Returns the inverse with respect to the parameter  $k$  of  $y = \text{nbdt r}(k, n, p)$ , the negative binomial cumulative distribution function.

<b>Parameters</b>	<b>y</b> : array_like	The probability of $k$ or fewer failures before $n$ successes (float).
	<b>n</b> : array_like	The target number of successes (positive int).
	<b>p</b> : array_like	Probability of success in a single event (float).
<b>Returns</b>	<b>k</b> : ndarray	The maximum number of allowed failures such that $\text{nbdt r}(k, n, p) = y$ .

**See also:**

**nbdt r** Cumulative distribution function of the negative binomial.  
**nbdt ri** Inverse with respect to  $p$  of  $\text{nbdt r}(k, n, p)$ .

**nbdttrin** Inverse with respect to  $n$  of  $nbdtr(k, n, p)$ .

**Notes**

Wrapper for the CDFLIB [R549] Fortran routine *cdfnbn*.

Formula 26.5.26 of [R550],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta  $I$ .

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

**References**

[R549], [R550]

`scipy.special.nbdttrin(k, y, p) = <ufunc 'nbdttrin'>`

Inverse of *nbdtr* vs  $n$ .

Returns the inverse with respect to the parameter  $n$  of  $y = nbdtr(k, n, p)$ , the negative binomial cumulative distribution function.

**Parameters**

- k** : array\_like  
The maximum number of allowed failures (nonnegative int).
- y** : array\_like  
The probability of  $k$  or fewer failures before  $n$  successes (float).
- p** : array\_like  
Probability of success in a single event (float).

**Returns**

- n** : ndarray  
The number of successes  $n$  such that  $nbdttr(k, n, p) = y$ .

**See also:**

**nbdttr** Cumulative distribution function of the negative binomial.  
**nbdttri** Inverse with respect to  $p$  of  $nbdttr(k, n, p)$ .  
**nbdttrik** Inverse with respect to  $k$  of  $nbdttr(k, n, p)$ .

**Notes**

Wrapper for the CDFLIB [R551] Fortran routine *cdfnbn*.

Formula 26.5.26 of [R552],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta  $I$ .

Computation of  $n$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $n$ .

**References**

[R551], [R552]

`scipy.special.ncfdtr(dfn, dfd, nc, f) = <ufunc 'ncfdtr'>`

Cumulative distribution function of the non-central F distribution.

The non-central F describes the distribution of,

$$Z = \frac{X/d_n}{Y/d_d}$$

where  $X$  and  $Y$  are independently distributed, with  $X$  distributed non-central  $\chi^2$  with noncentrality parameter  $nc$  and  $d_n$  degrees of freedom, and  $Y$  distributed  $\chi^2$  with  $d_d$  degrees of freedom.

**Parameters**

- dfn** : array\_like  
Degrees of freedom of the numerator sum of squares. Range (0, inf).
- dfd** : array\_like  
Degrees of freedom of the denominator sum of squares. Range (0, inf).
- nc** : array\_like  
Noncentrality parameter. Should be in range (0, 1e4).
- f** : array\_like  
Quantiles, i.e. the upper limit of integration.

**Returns**

- cdf** : float or ndarray  
The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

**See also:**

**ncfdtri** Quantile function; inverse of *ncfdtr* with respect to *f*.  
**ncfdtridf** Inverse of *ncfdtr* with respect to *dfd*.  
**ncfdtridf** Inverse of *ncfdtr* with respect to *dfn*.  
**ncfdtrinc** Inverse of *ncfdtr* with respect to *nc*.

**Notes**

Wrapper for the CDFLIB [R553] Fortran routine *cdffnc*.

The cumulative distribution function is computed using Formula 26.6.20 of [R554]:

$$F(d_n, d_d, n_c, f) = \sum_{j=0}^{\infty} e^{-n_c/2} \frac{(n_c/2)^j}{j!} I_x\left(\frac{d_n}{2} + j, \frac{d_d}{2}\right),$$

where  $I$  is the regularized incomplete beta function, and  $x = fd_n/(fd_n + d_d)$ .

The computation time required for this routine is proportional to the noncentrality parameter  $nc$ . Very large values of this parameter can consume immense computer resources. This is why the search range is bounded by 10,000.

**References**

[R553], [R554]

**Examples**

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

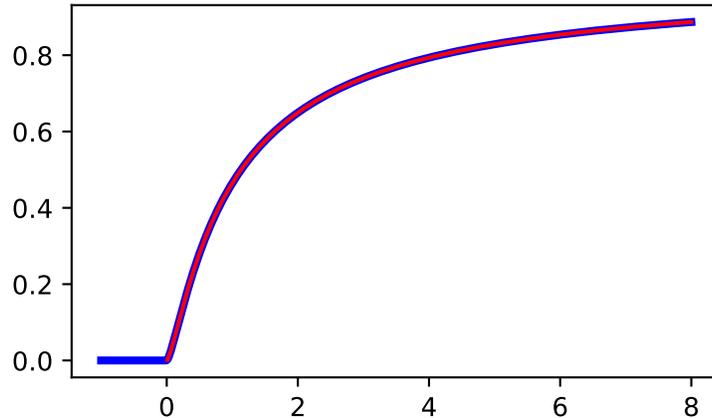

Plot the CDF of the non-central F distribution, for  $nc=0$ . Compare with the F-distribution from `scipy.stats`:

```
>>> x = np.linspace(-1, 8, num=500)
>>> dfn = 3
>>> dfd = 2
>>> ncf_stats = stats.f.cdf(x, dfn, dfd)
>>> ncf_special = special.ncfdtr(dfn, dfd, 0, x)
```

```

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, ncf_stats, 'b-', lw=3)
>>> ax.plot(x, ncf_special, 'r-')
>>> plt.show()

```

`scipy.special.ncfdtridfd(dfn, p, nc, f) = <ufunc 'ncfdtridfd'>`

Calculate degrees of freedom (denominator) for the noncentral F-distribution.

This is the inverse with respect to *dfd* of *ncfdtr*. See *ncfdtr* for more details.

**Parameters**

- dfn** : array\_like  
Degrees of freedom of the numerator sum of squares. Range (0, inf).
- p** : array\_like  
Value of the cumulative distribution function. Must be in the range [0, 1].
- nc** : array\_like  
Noncentrality parameter. Should be in range (0, 1e4).
- f** : array\_like  
Quantiles, i.e. the upper limit of integration.

**Returns**

- dfd** : float  
Degrees of freedom of the denominator sum of squares.

**See also:**

- ncfdtr** CDF of the non-central F distribution.
- ncfdtri** Quantile function; inverse of *ncfdtr* with respect to *f*.
- ncfdtridfn** Inverse of *ncfdtr* with respect to *dfn*.
- ncfdtrinc** Inverse of *ncfdtr* with respect to *nc*.

**Notes**

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

**Examples**

```
>>> from scipy.special import ncfdtr, ncfdtridfd
```

Compute the CDF for several values of *dfd*:

```
>>> dfd = [1, 2, 3]
>>> p = ncfdtr(2, dfd, 0.25, 15)
>>> p
array([ 0.8097138 ,  0.93020416,  0.96787852])
```

Compute the inverse. We recover the values of *dfd*, as expected:

```
>>> ncfdtridfd(2, p, 0.25, 15)
array([ 1.,  2.,  3.])
```

`scipy.special.ncfdtridfn(p, dfd, nc, f) = <ufunc 'ncfdtridfn'>`

Calculate degrees of freedom (numerator) for the noncentral F-distribution.

This is the inverse with respect to *dfn* of *ncfdtr*. See *ncfdtr* for more details.

<b>Parameters</b>	<b>p</b> : array_like	Value of the cumulative distribution function. Must be in the range [0, 1].
	<b>dfd</b> : array_like	Degrees of freedom of the denominator sum of squares. Range (0, inf).
	<b>nc</b> : array_like	Noncentrality parameter. Should be in range (0, 1e4).
	<b>f</b> : float	Quantiles, i.e. the upper limit of integration.
<b>Returns</b>	<b>dfn</b> : float	Degrees of freedom of the numerator sum of squares.

**See also:**

**ncfdtr** CDF of the non-central F distribution.  
**ncfdtri** Quantile function; inverse of *ncfdtr* with respect to *f*.  
**ncfdtridfd** Inverse of *ncfdtr* with respect to *dfd*.  
**ncfdtrinc** Inverse of *ncfdtr* with respect to *nc*.

**Notes**

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

**Examples**

```
>>> from scipy.special import ncfdtr, ncfdtridfn
```

Compute the CDF for several values of *dfn*:

```
>>> dfn = [1, 2, 3]
>>> p = ncfdtr(dfn, 2, 0.25, 15)
>>> p
array([ 0.92562363,  0.93020416,  0.93188394])
```

Compute the inverse. We recover the values of *dfn*, as expected:

```
>>> ncfdrtridf(p, 2, 0.25, 15)
array([ 1.,  2.,  3.])
```

`scipy.special.ncfdtri` (*dfn*, *dfd*, *nc*, *p*) = <ufunc 'ncfdtri'>

Inverse with respect to *f* of the CDF of the non-central F distribution.

See `ncfdtr` for more details.

<b>Parameters</b>	<b>dfn</b> : array_like	Degrees of freedom of the numerator sum of squares. Range (0, inf).
	<b>dfd</b> : array_like	Degrees of freedom of the denominator sum of squares. Range (0, inf).
	<b>nc</b> : array_like	Noncentrality parameter. Should be in range (0, 1e4).
	<b>p</b> : array_like	Value of the cumulative distribution function. Must be in the range [0, 1].
<b>Returns</b>	<b>f</b> : float	Quantiles, i.e. the upper limit of integration.

See also:

**ncfdtr** CDF of the non-central F distribution.

**ncfdtridf** Inverse of `ncfdtr` with respect to *dfd*.

**ncfdtridf** Inverse of `ncfdtr` with respect to *dfn*.

**ncfdtrinc** Inverse of `ncfdtr` with respect to *nc*.

**Examples**

```
>>> from scipy.special import ncfdrtr, ncfdrtri
```

Compute the CDF for several values of *f*:

```
>>> f = [0.5, 1, 1.5]
>>> p = ncfdrtr(2, 3, 1.5, f)
>>> p
array([ 0.20782291,  0.36107392,  0.47345752])
```

Compute the inverse. We recover the values of *f*, as expected:

```
>>> ncfdrtri(2, 3, 1.5, p)
array([ 0.5,  1. ,  1.5])
```

`scipy.special.ncfdtrinc` (*dfn*, *dfd*, *p*, *f*) = <ufunc 'ncfdtrinc'>

Calculate non-centrality parameter for non-central F distribution.

This is the inverse with respect to *nc* of `ncfdtr`. See `ncfdtr` for more details.

<b>Parameters</b>	<b>dfn</b> : array_like	Degrees of freedom of the numerator sum of squares. Range (0, inf).
	<b>dfd</b> : array_like	Degrees of freedom of the denominator sum of squares. Range (0, inf).
	<b>p</b> : array_like	Value of the cumulative distribution function. Must be in the range [0, 1].
	<b>f</b> : array_like	Quantiles, i.e. the upper limit of integration.
<b>Returns</b>	<b>nc</b> : float	Noncentrality parameter.

See also:

**ncfdtr** CDF of the non-central F distribution.  
**ncfdtri** Quantile function; inverse of *ncfdtr* with respect to *f*.  
**ncfdtridfd** Inverse of *ncfdtr* with respect to *dfd*.  
**ncfdtridfn** Inverse of *ncfdtr* with respect to *dfn*.

**Examples**

```
>>> from scipy.special import ncfdtr, ncftrin
```

Compute the CDF for several values of *nc*:

```
>>> nc = [0.5, 1.5, 2.0]
>>> p = ncfdtr(2, 3, nc, 15)
>>> p
array([ 0.96309246,  0.94327955,  0.93304098])
```

Compute the inverse. We recover the values of *nc*, as expected:

```
>>> ncftrin(2, 3, p, 15)
array([ 0.5,  1.5,  2. ])
```

`scipy.special.ncdtr(df, nc, t) = <ufunc 'ncdtr'>`

Cumulative distribution function of the non-central *t* distribution.

**Parameters**

- df**: array\_like  
Degrees of freedom of the distribution. Should be in range (0, inf).
- nc**: array\_like  
Noncentrality parameter. Should be in range (-1e6, 1e6).
- t**: array\_like  
Quantiles, i.e. the upper limit of integration.

**Returns**

- cdf**: float or ndarray  
The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

See also:

**ncdtrit** Inverse CDF (iCDF) of the non-central *t* distribution.  
**ncdtridf** Calculate degrees of freedom, given CDF and iCDF values.  
**ncdtrinc** Calculate non-centrality parameter, given CDF iCDF values.

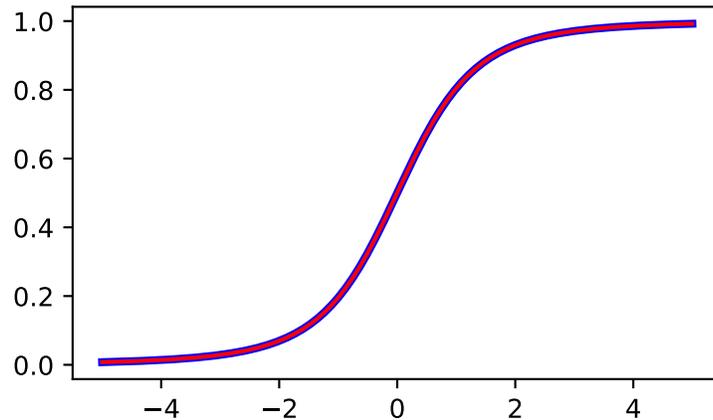

**Examples**

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central *t* distribution, for *nc*=0. Compare with the *t*-distribution from `scipy.stats`:

```
>>> x = np.linspace(-5, 5, num=500)
>>> df = 3
>>> nct_stats = stats.t.cdf(x, df)
>>> nct_special = special.ncdtr(df, 0, x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, nct_stats, 'b-', lw=3)
>>> ax.plot(x, nct_special, 'r-')
>>> plt.show()
```

`scipy.special.nctdtridf` ( $p, nc, t$ ) = <ufunc 'nctdtridf'>

Calculate degrees of freedom for non-central t distribution.

See `nctdtr` for more details.

**Parameters**

- p** : array\_like  
CDF values, in range (0, 1].
- nc** : array\_like  
Noncentrality parameter. Should be in range (-1e6, 1e6).
- t** : array\_like  
Quantiles, i.e. the upper limit of integration.

`scipy.special.nctdtrit` ( $df, nc, p$ ) = <ufunc 'nctdtrit'>

Inverse cumulative distribution function of the non-central t distribution.

See `nctdtr` for more details.

**Parameters**

- df** : array\_like  
Degrees of freedom of the distribution. Should be in range (0, inf).
- nc** : array\_like  
Noncentrality parameter. Should be in range (-1e6, 1e6).
- p** : array\_like  
CDF values, in range (0, 1].

`scipy.special.nctdtrinc` ( $df, p, t$ ) = <ufunc 'nctdtrinc'>

Calculate non-centrality parameter for non-central t distribution.

See `nctdtr` for more details.

**Parameters**

- df** : array\_like  
Degrees of freedom of the distribution. Should be in range (0, inf).
- p** : array\_like  
CDF values, in range (0, 1].
- t** : array\_like  
Quantiles, i.e. the upper limit of integration.

`scipy.special.nrdtrimn` ( $p, x, std$ ) = <ufunc 'nrdtrimn'>

Calculate mean of normal distribution given other params.

**Parameters**

- p** : array\_like

**Returns** **mn** : float or ndarray  
 CDF values, in range (0, 1].  
**x** : array\_like  
 Quantiles, i.e. the upper limit of integration.  
**std** : array\_like  
 Standard deviation.  
 The mean of the normal distribution.

**See also:***nrtrimn, ndtr*

`scipy.special.nrdtrisd(p, x, mn) = <ufunc 'nrdtrisd'>`  
 Calculate standard deviation of normal distribution given other params.

**Parameters** **p** : array\_like  
 CDF values, in range (0, 1].  
**x** : array\_like  
 Quantiles, i.e. the upper limit of integration.  
**mn** : float or ndarray  
 The mean of the normal distribution.  
**Returns** **std** : array\_like  
 Standard deviation.

**See also:***nrdtristd, ndtr*

`scipy.special.pdtr(k, m) = <ufunc 'pdtr'>`  
 Poisson cumulative distribution function  
 Returns the sum of the first  $k$  terms of the Poisson distribution:  $\sum(\exp(-m) * m^{**j} / j!, j=0..k) = \text{gammaincc}(k+1, m)$ . Arguments must both be positive and  $k$  an integer.

`scipy.special.pdtrc(k, m) = <ufunc 'pdtrc'>`  
 Poisson survival function  
 Returns the sum of the terms from  $k+1$  to infinity of the Poisson distribution:  $\sum(\exp(-m) * m^{**j} / j!, j=k+1..inf) = \text{gammainc}(k+1, m)$ . Arguments must both be positive and  $k$  an integer.

`scipy.special.pdtri(k, y) = <ufunc 'pdtri'>`  
 Inverse to *pdtr* vs  $m$   
 Returns the Poisson variable  $m$  such that the sum from 0 to  $k$  of the Poisson density is equal to the given probability  $y$ : calculated by  $\text{gammaincinv}(k+1, y)$ .  $k$  must be a nonnegative integer and  $y$  between 0 and 1.

`scipy.special.pdtrik(p, m) = <ufunc 'pdtrik'>`  
 Inverse to *pdtr* vs  $k$   
 Returns the quantile  $k$  such that  $\text{pdtr}(k, m) = p$

`scipy.special.stdtr(df, t) = <ufunc 'stdtr'>`  
 Student t distribution cumulative density function  
 Returns the integral from minus infinity to  $t$  of the Student t distribution with  $df > 0$  degrees of freedom:

```
gamma((df+1)/2) / (sqrt(df*pi) * gamma(df/2)) *
integral((1+x**2/df)**(-df/2-1/2), x=-inf..t)
```

`scipy.special.stdtridf(p, t) = <ufunc 'stdtridf'>`  
 Inverse of *stdtr* vs  $df$   
 Returns the argument  $df$  such that  $\text{stdtr}(df, t)$  is equal to  $p$ .

`scipy.special.stdtrit(df, p) = <ufunc 'stdtrit'>`

Inverse of `stdtr` vs `t`

Returns the argument `t` such that `stdtr(df, t)` is equal to `p`.

`scipy.special.chdtr(v, x) = <ufunc 'chdtr'>`

Chi square cumulative distribution function

Returns the area under the left hand tail (from 0 to `x`) of the Chi square probability density function with `v` degrees of freedom:

$$1 / (2^{v/2} * \text{gamma}(v/2)) * \text{integral}(t^{v/2-1} * \exp(-t/2), t=0..x)$$

`scipy.special.chdtrc(v, x) = <ufunc 'chdtrc'>`

Chi square survival function

Returns the area under the right hand tail (from `x` to infinity) of the Chi square probability density function with `v` degrees of freedom:

$$1 / (2^{v/2} * \text{gamma}(v/2)) * \text{integral}(t^{v/2-1} * \exp(-t/2), t=x..inf)$$

`scipy.special.chdtri(v, p) = <ufunc 'chdtri'>`

Inverse to `chdtrc`

Returns the argument `x` such that `chdtrc(v, x) == p`.

`scipy.special.chdtriv(p, x) = <ufunc 'chdtriv'>`

Inverse to `chdtr` vs `v`

Returns the argument `v` such that `chdtr(v, x) == p`.

`scipy.special.ndtr(x) = <ufunc 'ndtr'>`

Gaussian cumulative distribution function.

Returns the area under the standard Gaussian probability density function, integrated from minus infinity to `x`

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-t^2/2) dt$$

**Parameters** `x` : array\_like, real or complex

**Returns** ndarray Argument

The value of the normal CDF evaluated at `x`

**See also:**

`erf`, `erfc`, `scipy.stats.norm`, `log_ndtr`

`scipy.special.log_ndtr(x) = <ufunc 'log_ndtr'>`

Logarithm of Gaussian cumulative distribution function.

Returns the log of the area under the standard Gaussian probability density function, integrated from minus infinity to `x`:

$$\log(1/\text{sqrt}(2*\text{pi}) * \text{integral}(\exp(-t**2 / 2), t=-inf..x))$$

**Parameters** `x` : array\_like, real or complex

**Returns** ndarray Argument

The value of the log of the normal CDF evaluated at `x`

**See also:***erf, erfc, scipy.stats.norm, ndtr*`scipy.special.ndtri(y) = <ufunc 'ndtri'>`Inverse of *ndtr* vs *x*

Returns the argument *x* for which the area under the Gaussian probability density function (integrated from minus infinity to *x*) is equal to *y*.

`scipy.special.chndtr(x, df, nc) = <ufunc 'chndtr'>`

Non-central chi square cumulative distribution function

`scipy.special.chndtridf(x, p, nc) = <ufunc 'chndtridf'>`Inverse to *chndtr* vs *df*`scipy.special.chndtrinc(x, df, p) = <ufunc 'chndtrinc'>`Inverse to *chndtr* vs *nc*`scipy.special.chndtrix(p, df, nc) = <ufunc 'chndtrix'>`Inverse to *chndtr* vs *x*`scipy.special.smirnov(n, e) = <ufunc 'smirnov'>`

Kolmogorov-Smirnov complementary cumulative distribution function

Returns the exact Kolmogorov-Smirnov complementary cumulative distribution function (D<sub>n+</sub> or D<sub>n-</sub>) for a one-sided test of equality between an empirical and a theoretical distribution. It is equal to the probability that the maximum difference between a theoretical distribution and an empirical one based on *n* samples is greater than *e*.

`scipy.special.smirnovi(n, y) = <ufunc 'smirnovi'>`Inverse to *smirnov*

Returns *e* such that `smirnov(n, e) = y`.

`scipy.special.kolmogorov(y) = <ufunc 'kolmogorov'>`

Complementary cumulative distribution function of Kolmogorov distribution

Returns the complementary cumulative distribution function of Kolmogorov's limiting distribution (K<sub>n</sub>\* for large *n*) of a two-sided test for equality between an empirical and a theoretical distribution. It is equal to the (limit as *n*->infinity of the) probability that `sqrt(n) * max absolute deviation > y`.

`scipy.special.kolmogi(p) = <ufunc 'kolmogi'>`Inverse function to *kolmogorov*

Returns *y* such that `kolmogorov(y) == p`.

`scipy.special.tklmbda(x, lmbda) = <ufunc 'tklmbda'>`

Tukey-Lambda cumulative distribution function

`scipy.special.logit(x) = <ufunc 'logit'>`Logit ufunc for *ndarrays*.

The logit function is defined as `logit(p) = log(p/(1-p))`. Note that `logit(0) = -inf`, `logit(1) = inf`, and `logit(p)` for `p<0` or `p>1` yields `nan`.

**Parameters** *x* : *ndarray***Returns** *out* : *ndarray*The *ndarray* to apply *logit* to element-wise.

An *ndarray* of the same shape as *x*. Its entries are *logit* of the corresponding entry of *x*.

**See also:***expit*

**Notes**

As a ufunc `logit` takes a number of optional keyword arguments. For more information see [ufuncs](#)  
 New in version 0.10.0.

**Examples**

```
>>> from scipy.special import logit, expit
```

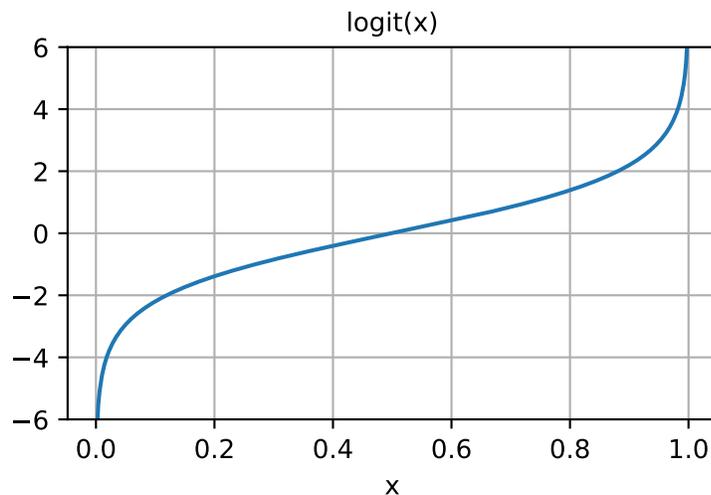

```
>>> logit([0, 0.25, 0.5, 0.75, 1])
array([-inf, -1.09861229, 0.          , 1.09861229,  inf])
```

`expit` is the inverse of `logit`:

```
>>> expit(logit([0.1, 0.75, 0.999]))
array([ 0.1   ,  0.75  ,  0.999])
```

Plot `logit(x)` for `x` in `[0, 1]`:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 1, 501)
>>> y = logit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.ylim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('logit(x)')
>>> plt.show()
```

`scipy.special.expit(x) = <ufunc 'expit'>`

Expit ufunc for ndarrays.

The `expit` function, also known as the logistic function, is defined as  $\text{expit}(x) = 1/(1+\exp(-x))$ . It is the inverse of the `logit` function.

**Parameters** `x` : ndarray

**Returns** `out` : ndarray The ndarray to apply `expit` to element-wise.

An ndarray of the same shape as `x`. Its entries are `expit` of the corresponding entry of `x`.

**See also:**

`logit`

**Notes**

As a ufunc `expit` takes a number of optional keyword arguments. For more information see [ufuncs](#)

New in version 0.10.0.

**Examples**

```
>>> from scipy.special import expit, logit
```

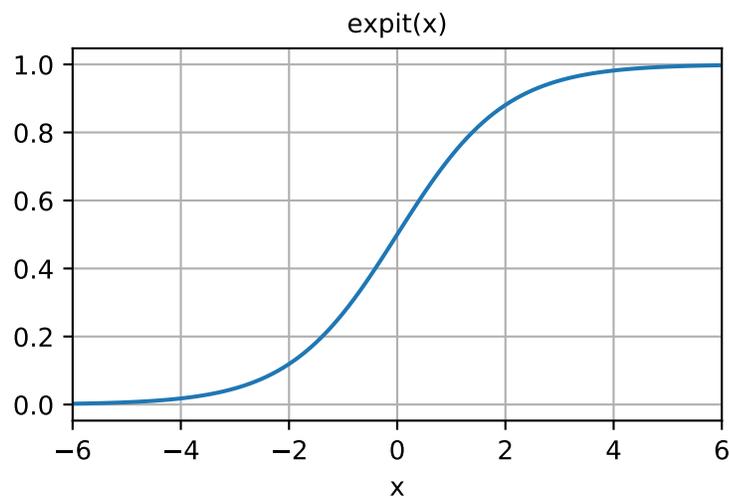

```
>>> expit([-np.inf, -1.5, 0, 1.5, np.inf])
array([ 0.          ,  0.18242552,  0.5          ,  0.81757448,  1.          ])
```

`logit` is the inverse of `expit`:

```
>>> logit(expit([-2.5, 0, 3.1, 5.0]))
array([-2.5,  0. ,  3.1,  5. ])
```

Plot `expit(x)` for `x` in `[-6, 6]`:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-6, 6, 121)
>>> y = expit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.xlim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('expit(x)')
>>> plt.show()
```

`scipy.special.boxcox(x, lambda) = <ufunc 'boxcox'>`  
 Compute the Box-Cox transformation.

The Box-Cox transformation is:

```
y = (x**lmbda - 1) / lmbda  if lmbda != 0
    log(x)                  if lmbda == 0
```

Returns *nan* if  $x < 0$ . Returns *-inf* if  $x == 0$  and  $lmbda < 0$ .

**Parameters** **x** : array\_like  
Data to be transformed.  
**lmbda** : array\_like  
Power parameter of the Box-Cox transform.

**Returns** **y** : array  
Transformed data.

### Notes

New in version 0.14.0.

### Examples

```
>>> from scipy.special import boxcox
>>> boxcox([1, 4, 10], 2.5)
array([ 0.          , 12.4          , 126.09110641])
>>> boxcox(2, [0, 1, 2])
array([ 0.69314718, 1.          , 1.5          ])
```

`scipy.special.boxcox1p(x, lmbda) = <ufunc 'boxcox1p'>`  
Compute the Box-Cox transformation of  $1 + x$ .

The Box-Cox transformation computed by `boxcox1p` is:

```
y = ((1+x)**lmbda - 1) / lmbda  if lmbda != 0
    log(1+x)                    if lmbda == 0
```

Returns *nan* if  $x < -1$ . Returns *-inf* if  $x == -1$  and  $lmbda < 0$ .

**Parameters** **x** : array\_like  
Data to be transformed.  
**lmbda** : array\_like  
Power parameter of the Box-Cox transform.

**Returns** **y** : array  
Transformed data.

### Notes

New in version 0.14.0.

### Examples

```
>>> from scipy.special import boxcox1p
>>> boxcox1p(1e-4, [0, 0.5, 1])
array([ 9.99950003e-05,  9.99975001e-05,  1.00000000e-04])
>>> boxcox1p([0.01, 0.1], 0.25)
array([ 0.00996272,  0.09645476])
```

`scipy.special.inv_boxcox(y, lmbda) = <ufunc 'inv_boxcox'>`  
Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

```
y = (x**lmbda - 1) / lmbda if lmbda != 0
    log(x)                  if lmbda == 0
```

**Parameters** **y** : array\_like  
Data to be transformed.

**lmbda** : array\_like  
Power parameter of the Box-Cox transform.

**Returns** **x** : array  
Transformed data.

**Notes**

New in version 0.16.0.

**Examples**

```
>>> from scipy.special import boxcox, inv_boxcox
>>> y = boxcox([1, 4, 10], 2.5)
>>> inv_boxcox(y, 2.5)
array([1., 4., 10.]
```

`scipy.special.inv_boxcox1p(y, lmbda) = <ufunc 'inv_boxcox1p'>`  
Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

```
y = ((1+x)**lmbda - 1) / lmbda if lmbda != 0
    log(1+x)                  if lmbda == 0
```

**Parameters** **y** : array\_like  
Data to be transformed.

**lmbda** : array\_like  
Power parameter of the Box-Cox transform.

**Returns** **x** : array  
Transformed data.

**Notes**

New in version 0.16.0.

**Examples**

```
>>> from scipy.special import boxcox1p, inv_boxcox1p
>>> y = boxcox1p([1, 4, 10], 2.5)
>>> inv_boxcox1p(y, 2.5)
array([1., 4., 10.]
```

**Information Theory Functions**

<code>entr(x)</code>	Elementwise function for computing entropy.
<code>rel_entr(x, y)</code>	Elementwise function for computing relative entropy.
<code>kl_div(x, y)</code>	Elementwise function for computing Kullback-Leibler divergence.
<code>huber(delta, r)</code>	Huber loss function.

Continued on next page

Table 5.256 – continued from previous page

<code>pseudo_huber(delta, r)</code>	Pseudo-Huber loss function.
-------------------------------------	-----------------------------

`scipy.special.entr(x) = <ufunc 'entr'>`  
 Elementwise function for computing entropy.

$$\text{entr}(x) = \begin{cases} -x \log(x) & x > 0 \\ 0 & x = 0 \\ -\infty & \text{otherwise} \end{cases}$$

**Parameters** `x` : ndarray  
 Input array.

**Returns** `res` : ndarray  
 The value of the elementwise entropy function at the given points `x`.

**See also:**

`kl_div`, `rel_entr`

**Notes**

This function is concave.

New in version 0.15.0.

`scipy.special.rel_entr(x, y) = <ufunc 'rel_entr'>`  
 Elementwise function for computing relative entropy.

$$\text{rel_entr}(x, y) = \begin{cases} x \log(x/y) & x > 0, y > 0 \\ 0 & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

**Parameters** `x` : ndarray  
 First input array.

`y` : ndarray  
 Second input array.

**Returns** `res` : ndarray  
 Output array.

**See also:**

`entr`, `kl_div`

**Notes**

This function is jointly convex in `x` and `y`.

New in version 0.15.0.

`scipy.special.kl_div(x, y) = <ufunc 'kl_div'>`  
 Elementwise function for computing Kullback-Leibler divergence.

$$\text{kl_div}(x, y) = \begin{cases} x \log(x/y) - x + y & x > 0, y > 0 \\ y & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

**Parameters** `x` : ndarray  
 First input array.

`y` : ndarray

**Returns** **res** : ndarray Second input array.  
Output array.

**See also:**

*entr, rel\_entr*

**Notes**

This function is non-negative and is jointly convex in  $x$  and  $y$ .

New in version 0.15.0.

`scipy.special.huber` ( $\delta, r$ ) = <ufunc 'huber'>  
Huber loss function.

$$\text{huber}(\delta, r) = \begin{cases} \infty & \delta < 0 \\ \frac{1}{2}r^2 & 0 \leq \delta, |r| \leq \delta \\ \delta(|r| - \frac{1}{2}\delta) & \text{otherwise} \end{cases}$$

**Parameters** **delta** : ndarray Input array, indicating the quadratic vs. linear loss changepoint.  
**r** : ndarray Input array, possibly representing residuals.

**Returns** **res** : ndarray The computed Huber loss function values.

**Notes**

This function is convex in  $r$ .

New in version 0.15.0.

`scipy.special.pseudo_huber` ( $\delta, r$ ) = <ufunc 'pseudo\_huber'>  
Pseudo-Huber loss function.

$$\text{pseudo\_huber}(\delta, r) = \delta^2 \left( \sqrt{1 + \left(\frac{r}{\delta}\right)^2} - 1 \right)$$

**Parameters** **delta** : ndarray Input array, indicating the soft quadratic vs. linear loss changepoint.  
**r** : ndarray Input array, possibly representing residuals.

**Returns** **res** : ndarray The computed Pseudo-Huber loss function values.

**Notes**

This function is convex in  $r$ .

New in version 0.15.0.

**Gamma and Related Functions**

<i>gamma</i> (z)	Gamma function.
<i>gamma</i> ln(x, /[, out, where, casting, order, ...])	Logarithm of the absolute value of the Gamma function.
<i>loggamma</i> (z[, out])	Principal branch of the logarithm of the Gamma function.

Continued on next page

Table 5.257 – continued from previous page

<code>gammasgn(x)</code>	Sign of the gamma function.
<code>gammainc(a, x)</code>	Regularized lower incomplete gamma function.
<code>gammaincinv(a, y)</code>	Inverse to <code>gammainc</code>
<code>gammaincc(a, x)</code>	Regularized upper incomplete gamma function.
<code>gammainccinv(a, y)</code>	Inverse to <code>gammaincc</code>
<code>beta(a, b)</code>	Beta function.
<code>betaln(a, b)</code>	Natural logarithm of absolute value of beta function.
<code>betainc(a, b, x)</code>	Incomplete beta integral.
<code>betaincinv(a, b, y)</code>	Inverse function to beta integral.
<code>psi(z[, out])</code>	The digamma function.
<code>rgamma(z)</code>	Gamma function inverted
<code>polygamma(n, x)</code>	Polygamma function n.
<code>multigammaln(a, d)</code>	Returns the log of multivariate gamma, also sometimes called the generalized gamma.
<code>digamma(z[, out])</code>	The digamma function.
<code>poch(z, m)</code>	Rising factorial (z)_m

`scipy.special.gamma(z) = <ufunc 'gamma'>`  
 Gamma function.

$$\Gamma(z) = \int_0^{\infty} x^{z-1} e^{-x} dx = (z-1)!$$

The gamma function is often referred to as the generalized factorial since  $z \cdot \text{gamma}(z) = \text{gamma}(z+1)$  and  $\text{gamma}(n+1) = n!$  for natural number  $n$ .

**Parameters** `z`: float or complex array\_like  
**Returns** float or complex  
 The value(s) of `gamma(z)`

### Examples

```
>>> from scipy.special import gamma, factorial
```

```
>>> gamma([0, 0.5, 1, 5])
array([      inf,  1.77245385,  1.         ,  24.         ])
```

```
>>> z = 2.5 + 1j
>>> gamma(z)
(0.77476210455108352+0.70763120437959293j)
>>> gamma(z+1), z*gamma(z) # Recurrence property
((1.2292740569981171+2.5438401155000685j),
 (1.2292740569981158+2.5438401155000658j))
```

```
>>> gamma(0.5)**2 # gamma(0.5) = sqrt(pi)
3.1415926535897927
```

Plot `gamma(x)` for real `x`

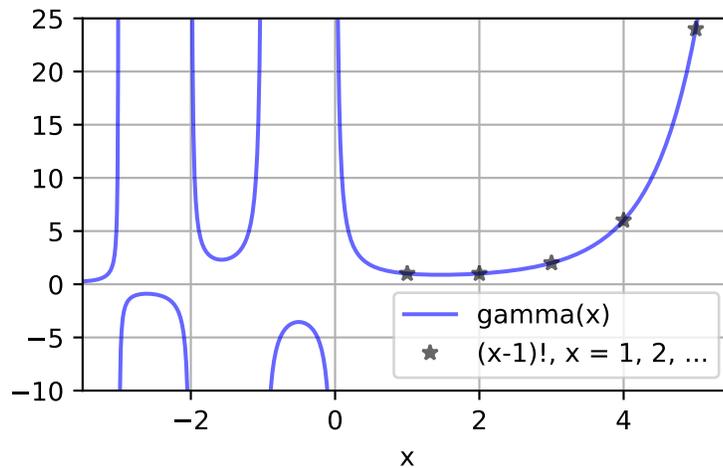

```
>>> x = np.linspace(-3.5, 5.5, 2251)
>>> y = gamma(x)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'b', alpha=0.6, label='gamma(x)')
```

```

>>> k = np.arange(1, 7)
>>> plt.plot(k, factorial(k-1), 'k*', alpha=0.6,
...         label='(x-1)!, x = 1, 2, ...')
>>> plt.xlim(-3.5, 5.5)
>>> plt.ylim(-10, 25)
>>> plt.grid()
>>> plt.xlabel('x')
>>> plt.legend(loc='lower right')
>>> plt.show()

```

`scipy.special.gammaln` (*x*, /, *out=None*, \*, *where=True*, *casting='same\_kind'*, *order='K'*, *dtype=None*, *subok=True*, [*signature*, *extobj*]) = <ufunc 'gammaln'>  
 Logarithm of the absolute value of the Gamma function.

**Parameters** *x*: array-like

**Returns** `gammaln`: ndarray  
 Values on the real line at which to compute `gammaln`  
 Values of `gammaln` at *x*.

**See also:**

`gamma` sign of the gamma function

`loggamma` principal branch of the logarithm of the gamma function

**Notes**

When used in conjunction with `gamma`, this function is useful for working in logspace on the real axis without having to deal with complex numbers, via the relation  $\exp(\text{gammaln}(x)) = \text{gamma}(x) * \text{gamma}(x)$ .

For complex-valued log-gamma, use `loggamma` instead of `gammaln`.

`scipy.special.loggamma` (*z*, *out=None*) = <ufunc 'loggamma'>

Principal branch of the logarithm of the Gamma function.

Defined to be  $\log(\Gamma(x))$  for  $x > 0$  and extended to the complex plane by analytic continuation. The function has a single branch cut on the negative real axis.

New in version 0.18.0.

**Parameters** *z*: array-like

Values in the complex plain at which to compute `loggamma`

**out** : ndarray, optional

**Returns** **loggamma** : ndarray  
 Output array for computed values of `loggamma`  
 Values of `loggamma` at `z`.

**See also:**

**gamma1n** logarithm of the absolute value of the Gamma function  
**gamma1sgn** sign of the gamma function

**Notes**

It is not generally true that  $\log \Gamma(z) = \log(\Gamma(z))$ , though the real parts of the functions do agree. The benefit of not defining `loggamma` as  $\log(\Gamma(z))$  is that the latter function has a complicated branch cut structure whereas `loggamma` is analytic except for on the negative real axis.

The identities

$$\begin{aligned} \exp(\log \Gamma(z)) &= \Gamma(z) \\ \log \Gamma(z + 1) &= \log(z) + \log \Gamma(z) \end{aligned}$$

make `loggamma` useful for working in complex logspace. However, `loggamma` necessarily returns complex outputs for real inputs, so if you want to work only with real numbers use `gamma1n`. On the real line the two functions are related by  $\exp(\loggamma(x)) = \text{gamma1sgn}(x) * \exp(\text{gamma1n}(x))$ , though in practice rounding errors will introduce small spurious imaginary components in  $\exp(\loggamma(x))$ .

The implementation here is based on [hare1997].

[hare1997]

`scipy.special.gamma1sgn(x)` = <ufunc 'gamma1sgn'>  
 Sign of the gamma function.

**See also:**

`gamma1n`, `loggamma`

`scipy.special.gammainc(a, x)` = <ufunc 'gammainc'>  
 Regularized lower incomplete gamma function.

Defined as

$$\frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . The function satisfies the relation  $\text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1$  where `gammaincc` is the regularized upper incomplete gamma function.

**See also:**

**gammaincc** regularized upper incomplete gamma function  
**gammaincinv**  
 inverse to `gammainc` versus `x`  
**gammainccinv**  
 inverse to `gammaincc` versus `x`

**Notes**

The implementation largely follows that of [R470].

**References***[R470]*`scipy.special.gammaincinv(a, y) = <ufunc 'gammaincinv'>`Inverse to *gammainc*Returns *x* such that `gammainc(a, x) = y`.`scipy.special.gammaincc(a, x) = <ufunc 'gammaincc'>`

Regularized upper incomplete gamma function.

Defined as

$$\frac{1}{\Gamma(a)} \int_x^{\infty} t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . The function satisfies the relation `gammainc(a, x) + gammaincc(a, x) = 1` where *gammainc* is the regularized lower incomplete gamma function.

**See also:****gammainc** regularized lower incomplete gamma function**gammaincinv**inverse to *gammainc* versus *x***gammainccinv**inverse to *gammaincc* versus *x***Notes**The implementation largely follows that of *[R471]*.**References***[R471]*`scipy.special.gammainccinv(a, y) = <ufunc 'gammainccinv'>`Inverse to *gammaincc*Returns *x* such that `gammaincc(a, x) == y`.`scipy.special.beta(a, b) = <ufunc 'beta'>`

Beta function.

$$\text{beta}(a, b) = \text{gamma}(a) * \text{gamma}(b) / \text{gamma}(a+b)$$

`scipy.special.betaln(a, b) = <ufunc 'betaln'>`

Natural logarithm of absolute value of beta function.

Computes `ln(abs(beta(a, b)))`.`scipy.special.betainc(a, b, x) = <ufunc 'betainc'>`

Incomplete beta integral.

Compute the incomplete beta integral of the arguments, evaluated from zero to *x*:

$$\text{gamma}(a+b) / (\text{gamma}(a) * \text{gamma}(b)) * \text{integral}(t^{a-1} (1-t)^{b-1}, t=0..x)$$

**Notes**

The incomplete beta is also sometimes defined without the terms in gamma, in which case the above definition is the so-called regularized incomplete beta. Under this definition, you can get the incomplete beta by multiplying the result of the scipy function by `beta(a, b)`.

`scipy.special.betaincinv(a, b, y) = <ufunc 'betaincinv'>`  
 Inverse function to beta integral.

Compute  $x$  such that  $\text{betainc}(a, b, x) = y$ .

`scipy.special.psi(z, out=None) = <ufunc 'psi'>`  
 The digamma function.

The logarithmic derivative of the gamma function evaluated at  $z$ .

**Parameters** `z` : array\_like  
 Real or complex argument.  
`out` : ndarray, optional  
 Array for the computed values of `psi`.  
**Returns** `digamma` : ndarray  
 Computed values of `psi`.

**Notes**

For large values not close to the negative real axis `psi` is computed using the asymptotic series (5.11.2) from [R562]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [R562] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [R562] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [R563], so the function should maintain full accuracy around the origin.

**References**

[R562], [R563]

`scipy.special.rgamma(z) = <ufunc 'rgamma'>`  
 Gamma function inverted

Returns  $1/\text{gamma}(x)$

`scipy.special.polygamma(n, x)`  
 Polygamma function  $n$ .

This is the  $n$ th derivative of the digamma (`psi`) function.

**Parameters** `n` : array\_like of int  
 The order of the derivative of `psi`.  
`x` : array\_like  
 Where to evaluate the polygamma function.  
**Returns** `polygamma` : ndarray  
 The result.

**Examples**

```
>>> from scipy import special
>>> x = [2, 3, 25.5]
>>> special.polygamma(1, x)
array([ 0.64493407,  0.39493407,  0.03999467])
>>> special.polygamma(0, x) == special.psi(x)
array([ True,  True,  True], dtype=bool)
```

`scipy.special.multigammaln(a, d)`  
 Returns the log of multivariate gamma, also sometimes called the generalized gamma.

**Parameters** `a` : ndarray

**Returns**

- d** : int The multivariate gamma is computed for each item of *a*.
- res** : ndarray The dimension of the space of integration.
- The values of the log multivariate gamma at the given points *a*.

**Notes**

The formal definition of the multivariate gamma of dimension *d* for a real *a* is

$$\Gamma_d(a) = \int_{A>0} e^{-tr(A)} |A|^{a-(d+1)/2} dA$$

with the condition  $a > (d - 1)/2$ , and  $A > 0$  being the set of all the positive definite matrices of dimension *d*. Note that *a* is a scalar: the integrand only is multivariate, the argument is not (the function is defined over a subset of the real set).

This can be proven to be equal to the much friendlier equation

$$\Gamma_d(a) = \pi^{d(d-1)/4} \prod_{i=1}^d \Gamma(a - (i - 1)/2).$$

**References**

R. J. Muirhead, Aspects of multivariate statistical theory (Wiley Series in probability and mathematical statistics).

`scipy.special.digamma` (*z*, *out=None*) = <ufunc 'psi'>

The digamma function.

The logarithmic derivative of the gamma function evaluated at *z*.

**Parameters**

- z** : array\_like Real or complex argument.
- out** : ndarray, optional

**Returns**

- digamma** : ndarray Array for the computed values of `psi`.
- Computed values of `psi`.

**Notes**

For large values not close to the negative real axis `psi` is computed using the asymptotic series (5.11.2) from [R441]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [R441] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [R441] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [R442], so the function should maintain full accuracy around the origin.

`scipy.special.poch` (*z*, *m*) = <ufunc 'poch'>

Rising factorial (*z*)<sub>*m*</sub>

The Pochhammer symbol (rising factorial), is defined as

$$(z)_m = \frac{\Gamma(z + m)}{\Gamma(z)}$$

For positive integer  $m$  it reads

$$(z)_m = z(z + 1)\dots(z + m - 1)$$

**Parameters** **z** : array\_like  
(int or float)  
**m** : array\_like  
(int or float)

**Returns** **poch** : ndarray  
The value of the function.

## Error Function and Fresnel Integrals

<code>erf(z)</code>	Returns the error function of complex argument.
<code>erfc(x)</code>	Complementary error function, $1 - \text{erf}(x)$ .

**Examples**

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-3, 3)
>>> z = special.wofz(x)
```

```
>>> plt.plot(x, z.real, label='wofz(x).real')
>>> plt.plot(x, z.imag, label='wofz(x).imag')
>>> plt.xlabel('$x$')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.show()
```

`scipy.special.dawsn(x) = <ufunc 'dawsn'>`

Dawson's integral.

Computes:

```
exp(-x**2) * integral(exp(t**2), t=0..x).
```

**See also:**

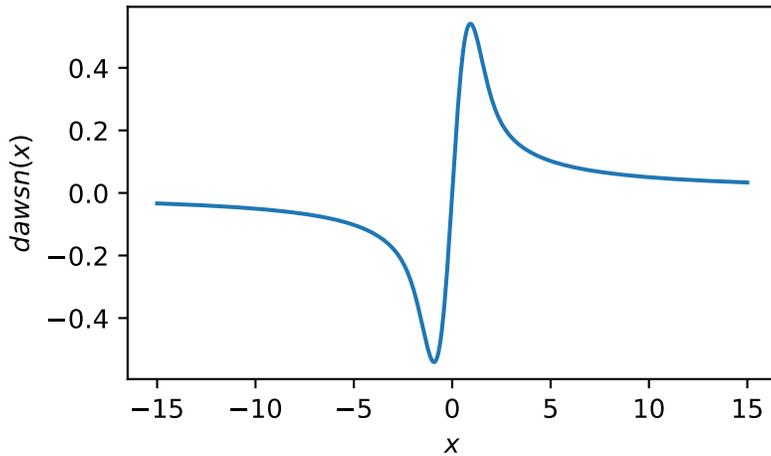

*wofz, erf, erfc, erfcx, erfi*

**References**

[R440]

**Examples**

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-15, 15, num=1000)
>>> plt.plot(x, special.dawsn(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$dawsn(x)$')
>>> plt.show()
```

`scipy.special.fresnel(z) = <ufunc 'fresnel'>`

Fresnel sin and cos integrals

Defined as:

```
ssa = integral(sin(pi/2 * t**2), t=0..z)
csa = integral(cos(pi/2 * t**2), t=0..z)
```

**Parameters** **z** : float or complex array\_like  
Argument

**Returns** ssa, csa  
Fresnel sin and cos integral values

`scipy.special.fresnel_zeros(nt)`

Compute nt complex zeros of sine and cosine Fresnel integrals S(z) and C(z).

**References**

[R467]

`scipy.special.modfresnelp(x) = <ufunc 'modfresnelp'>`

Modified Fresnel positive integrals

**Returns** fp  
Integral  $F_+(x)$ :  $\text{integral}(\exp(1j*t*t), t=x..inf)$

kp  
Integral  $K_+(x)$ :  $1/\text{sqrt}(\pi) * \exp(-1j*(x*x+\pi/4)) * fp$

`scipy.special.modfresnelm(x) = <ufunc 'modfresnelm'>`

Modified Fresnel negative integrals

**Returns** fm  
Integral  $F_-(x)$ :  $\text{integral}(\exp(-1j*t*t), t=x..inf)$

km  
Integral  $K_-(x)$ :  $1/\text{sqrt}(\pi) * \exp(1j*(x*x+\pi/4)) * fp$

These are not universal functions:

**Legendre Functions**

<code>lpmv(m, v, x)</code>	Associated Legendre function of integer order and real degree.
<code>sph_harm(m, n, theta, phi)</code>	Compute spherical harmonics.

`scipy.special.lpmv` (*m*, *v*, *x*) = <ufunc 'lpmv'>  
 Associated Legendre function of integer order and real degree.

Defined as

$$P_v^m = (-1)^m (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_v(x)$$

where

$$P_v = \sum_{k=0}^{\infty} \frac{(-v)_k (v+1)_k}{(k!)^2} \left( \frac{1-x}{2} \right)^k$$

is the Legendre function of the first kind. Here  $(\cdot)_k$  is the Pochhammer symbol; see `poch`.

**Parameters** **m** : array\_like

Order (int or float). If passed a float not equal to an integer the function returns NaN.

**v** : array\_like

Degree (float).

**x** : array\_likeArgument (float). Must have  $|x| \leq 1$ .**Returns****pmv** : ndarray

Value of the associated Legendre function.

**See also:**

- lpmn** Compute the associated Legendre function for all orders 0, ..., m and degrees 0, ..., n.
- clpmn** Compute the associated Legendre function at complex arguments.

**Notes**

Note that this implementation includes the Condon-Shortley phase.

**References**

[R538]

`scipy.special.sph_harm(m, n, theta, phi) = <ufunc 'sph_harm'>`

Compute spherical harmonics.

The spherical harmonics are defined as

$$Y_n^m(\theta, \phi) = \sqrt{\frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!}} e^{im\theta} P_n^m(\cos(\phi))$$

where  $P_n^m$  are the associated Legendre functions; see *lpmv*.

- Parameters**
- m** : array\_like  
Order of the harmonic (int); must have  $|m| \leq n$ .
  - n** : array\_like  
Degree of the harmonic (int); must have  $n \geq 0$ . This is often denoted by  $l$  (lower case L) in descriptions of spherical harmonics.
  - theta** : array\_like  
Azimuthal (longitudinal) coordinate; must be in  $[0, 2\pi]$ .
  - phi** : array\_like  
Polar (colatitudinal) coordinate; must be in  $[0, \pi]$ .
- Returns**
- y\_mn** : complex float  
The harmonic  $Y_n^m$  sampled at `theta` and `phi`.

**Notes**

There are different conventions for the meanings of the input arguments `theta` and `phi`. In SciPy `theta` is the azimuthal angle and `phi` is the polar angle. It is common to see the opposite convention, that is, `theta` as the polar angle and `phi` as the azimuthal angle.

Note that SciPy's spherical harmonics include the Condon-Shortley phase [R575] because it is part of *lpmv*.

With SciPy's conventions, the first several spherical harmonics are

$$\begin{aligned}
 Y_0^0(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{1}{\pi}} \\
 Y_1^{-1}(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{-i\theta} \sin(\phi) \\
 Y_1^0(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{3}{\pi}} \cos(\phi) \\
 Y_1^1(\theta, \phi) &= -\frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{i\theta} \sin(\phi).
 \end{aligned}$$

**References**

[R574], [R575]

These are not universal functions:

<code>clpmn(m, n, z[, type])</code>	Associated Legendre function of the first kind for complex arguments.
<code>lpn(n, z)</code>	Legendre function of the first kind.
<code>lqn(n, z)</code>	Legendre function of the second kind.

<code>lqmn(m, n, z)</code>	Sequence of associated Legendre functions of the second kind.

`scipy.special.clpmn(m, n, z, type=3)`

Associated Legendre function of the first kind for complex arguments.

Computes the associated Legendre function of the first kind of order  $m$  and degree  $n$ ,  $P_{mn}(z) = P_n^m(z)$ , and its derivative,  $P_{mn}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $P_{mn}(z)$  and  $P_{mn}'(z)$  for all orders from  $0 \dots m$  and degrees from  $0 \dots n$ .

**Parameters** **m** : int

$|m| \leq n$ ; the order of the Legendre function.

**n** : int

where  $n \geq 0$ ; the degree of the Legendre function. Often called  $l$  (lower case L) in descriptions of the associated Legendre function

**z** : float or complex

Input value.

**type** : int, optional

takes values 2 or 3 2: cut on the real axis  $|x| > 1$  3: cut on the real axis

**Returns** **Pmn\_z** :  $(m+1, n+1)$  array  $^{-1} \leq x \leq 1$  (default)

Values for all orders  $0 \dots m$  and degrees  $0 \dots n$

**Pmn\_d\_z** :  $(m+1, n+1)$  array

Derivatives for all orders  $0 \dots m$  and degrees  $0 \dots n$

**See also:**

**lpmn** associated Legendre functions of the first kind for real  $z$

**Notes**

By default, i.e. for `type=3`, phase conventions are chosen according to [R437] such that the function is analytic. The cut lies on the interval  $(-1, 1)$ . Approaching the cut from above or below in general yields a phase factor with respect to Ferrer's function of the first kind (cf. `lpmn`).

For `type=2` a cut at  $|x| > 1$  is chosen. Approaching the real values on the interval  $(-1, 1)$  in the complex plane yields Ferrer's function of the first kind.

**References**

[R437], [R438]

`scipy.special.lpn(n, z)`

Legendre function of the first kind.

Compute sequence of Legendre functions of the first kind (polynomials),  $P_n(z)$  and derivatives for all degrees from 0 to  $n$  (inclusive).

See also `special.legendre` for polynomial class.

**References**

[R539]

`scipy.special.lqgn` (*n*, *z*)

Legendre function of the second kind.

Compute sequence of Legendre functions of the second kind,  $Q_n(z)$  and derivatives for all degrees from 0 to *n* (inclusive).

**References**

[R541]

`scipy.special.lpmn` (*m*, *n*, *z*)

Sequence of associated Legendre functions of the first kind.

Computes the associated Legendre function of the first kind of order *m* and degree *n*,  $P_{mn}(z) = P_n^m(z)$ , and its derivative,  $P_{mn}'(z)$ . Returns two arrays of size (*m*+1, *n*+1) containing  $P_{mn}(z)$  and  $P_{mn}'(z)$  for all orders from 0..*m* and degrees from 0..*n*.

This function takes a real argument *z*. For complex arguments *z* use `clpmn` instead.

**Parameters**

**m** : int  
 |*m*| <= *n*; the order of the Legendre function.

**n** : int  
 where *n* >= 0; the degree of the Legendre function. Often called *l* (lower case L) in descriptions of the associated Legendre function

**z** : float

**Returns**

**Pmn\_z** : (*m*+1, *n*+1) array  
 Input value.  
 Values for all orders 0..*m* and degrees 0..*n*

**Pmn\_d\_z** : (*m*+1, *n*+1) array  
 Derivatives for all orders 0..*m* and degrees 0..*n*

**See also:**

**clpmn** associated Legendre functions of the first kind for complex *z*

**Notes**

In the interval (-1, 1), Ferrer's function of the first kind is returned. The phase convention used for the intervals (1, inf) and (-inf, -1) is such that the result is always real.

[R536], [R537]

`scipy.special.lqmn` (*m*, *n*, *z*)

Sequence of associated Legendre functions of the second kind.

Computes the associated Legendre function of the second kind of order *m* and degree *n*,  $Q_{mn}(z) = Q_n^m(z)$ , and its derivative,  $Q_{mn}'(z)$ . Returns two arrays of size (*m*+1, *n*+1) containing  $Q_{mn}(z)$  and  $Q_{mn}'(z)$  for all orders from 0..*m* and degrees from 0..*n*.

**Parameters**

**m** : int  
 |*m*| <= *n*; the order of the Legendre function.

**n** : int  
 where *n* >= 0; the degree of the Legendre function. Often called *l* (lower case L) in descriptions of the associated Legendre function

**z** : complex

**Returns**

**Qmn\_z** : (*m*+1, *n*+1) array  
 Input value.

Values for all orders 0..m and degrees 0..n  
**Qmn\_d\_z** : (m+1, n+1) array  
 Derivatives for all orders 0..m and degrees 0..n

## Ellipsoidal Harmonics

<code>ellip_harm(h2, k2, n, p, s[, signm, signn])</code>	Ellipsoidal harmonic functions $E^p_n(l)$
<code>ellip_harm_2(h2, k2, n, p, s)</code>	Ellipsoidal harmonic functions $F^p_n(l)$
<code>ellip_normal(h2, k2, n, p)</code>	Ellipsoidal harmonic normalization constants $\gamma^p_n$

`scipy.special.ellip_harm` (*h2, k2, n, p, s, signm=1, signn=1*)  
 Ellipsoidal harmonic functions  $E^p_n(l)$

These are also known as Lamé functions of the first kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)E''(s) + s(2s^2 - h^2 - k^2)E'(s) + (a - qs^2)E(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

**Parameters**

- h2** : float  
h\*\*2
- k2** : float  
k\*\*2; should be larger than h\*\*2
- n** : int  
Degree
- s** : float  
Coordinate
- p** : int  
Order, can range between [1,2n+1]
- signm** : {1, -1}, optional  
Sign of prefactor of functions. Can be +/-1. See Notes.
- signn** : {1, -1}, optional  
Sign of prefactor of functions. Can be +/-1. See Notes.

**Returns**

- E** : float  
the harmonic  $E^p_n(s)$

### See also:

`ellip_harm_2`, `ellip_normal`

### Notes

The geometric interpretation of the ellipsoidal functions is explained in [R444], [R445], [R446]. The *signm* and *signn* arguments control the sign of prefactors for functions according to their type:

<pre>K : +1 L : signm M : signn N : signm*signn</pre>
---

New in version 0.15.0.

[R443], [R444], [R445], [R446]

**Examples**

```
>>> from scipy.special import ellip_harm
>>> w = ellip_harm(5, 8, 1, 1, 2.5)
>>> w
2.5
```

Check that the functions indeed are solutions to the Lamé equation:

```
>>> from scipy.interpolate import UnivariateSpline
>>> def eigenvalue(f, df, ddf):
...     r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 - k**2)*df -
->n*(n+1)*s**2*f)/f
...     return -r.mean(), r.std()
>>> s = np.linspace(0.1, 10, 200)
>>> k, h, n, p = 8.0, 2.2, 3, 2
>>> E = ellip_harm(h**2, k**2, n, p, s)
>>> E_spl = UnivariateSpline(s, E)
>>> a, a_err = eigenvalue(E_spl(s), E_spl(s,1), E_spl(s,2))
>>> a, a_err
(583.44366156701483, 6.4580890640310646e-11)
```

scipy.special.**ellip\_harm\_2** (*h2, k2, n, p, s*)

Ellipsoidal harmonic functions  $F^p_n(l)$

These are also known as Lamé functions of the second kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)F''(s) + s(2s^2 - h^2 - k^2)F'(s) + (a - qs^2)F(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

<b>Parameters</b>	<b>h2</b> : float	$h^{*2}$
	<b>k2</b> : float	$k^{*2}$ ; should be larger than $h^{*2}$
	<b>n</b> : int	Degree.
	<b>p</b> : int	Order, can range between $[1, 2n+1]$ .
	<b>s</b> : float	Coordinate
<b>Returns</b>	<b>F</b> : float	The harmonic $F^p_n(s)$

**See also:**

*ellip\_harm, ellip\_normal*

**Notes**

Lamé functions of the second kind are related to the functions of the first kind:

$$F^p_n(s) = (2n + 1)E^p_n(s) \int_0^{1/s} \frac{du}{(E^p_n(1/u))^2 \sqrt{(1 - u^2k^2)(1 - u^2h^2)}}$$

New in version 0.15.0.

**Examples**

```
>>> from scipy.special import ellip_harm_2
>>> w = ellip_harm_2(5, 8, 2, 1, 10)
>>> w
0.00108056853382
```

`scipy.special.ellip_normal` (*h2*, *k2*, *n*, *p*)

Ellipsoidal harmonic normalization constants  $\gamma_n^p$

The normalization constant is defined as

$$\gamma_n^p = 8 \int_0^h dx \int_h^k dy \frac{(y^2 - x^2)(E_n^p(y)E_n^p(x))^2}{\sqrt{((k^2 - y^2)(y^2 - h^2)(h^2 - x^2)(k^2 - x^2))}}$$

**Parameters**

- h2** : float  
h\*\*2
- k2** : float  
k\*\*2; should be larger than h\*\*2
- n** : int  
Degree.
- p** : int  
Order, can range between [1,2n+1].

**Returns**

- gamma** : float  
The normalization constant  $\gamma_n^p$

**See also:**

`ellip_harm`, `ellip_harm_2`

**Notes**

New in version 0.15.0.

**Examples**

```
>>> from scipy.special import ellip_normal
>>> w = ellip_normal(5, 8, 3, 7)
>>> w
1723.38796997
```

**Orthogonal polynomials**

The following functions evaluate values of orthogonal polynomials:

<code>assoc_laguerre(x, n[, k])</code>	Compute the generalized (associated) Laguerre polynomial of degree <i>n</i> and order <i>k</i> .
<code>eval_legendre(n, x[, out])</code>	Evaluate Legendre polynomial at a point.
<code>eval_chebyt(n, x[, out])</code>	Evaluate Chebyshev polynomial of the first kind at a point.
<code>eval_chebyu(n, x[, out])</code>	Evaluate Chebyshev polynomial of the second kind at a point.
<code>eval_chebyc(n, x[, out])</code>	Evaluate Chebyshev polynomial of the first kind on [-2, 2] at a point.
<code>eval_chebys(n, x[, out])</code>	Evaluate Chebyshev polynomial of the second kind on [-2, 2] at a point.
<code>eval_jacobi(n, alpha, beta, x[, out])</code>	Evaluate Jacobi polynomial at a point.

Continued on next page

Table 5.263 – continued from previous page

<code>eval_laguerre(n, x[, out])</code>	Evaluate Laguerre polynomial at a point.
<code>eval_genlaguerre(n, alpha, x[, out])</code>	Evaluate generalized Laguerre polynomial at a point.
<code>eval_hermite(n, x[, out])</code>	Evaluate physicist's Hermite polynomial at a point.
<code>eval_hermitenorm(n, x[, out])</code>	Evaluate probabilist's (normalized) Hermite polynomial at a point.
<code>eval_gegenbauer(n, alpha, x[, out])</code>	Evaluate Gegenbauer polynomial at a point.
<code>eval_sh_legendre(n, x[, out])</code>	Evaluate shifted Legendre polynomial at a point.
<code>eval_sh_chebyt(n, x[, out])</code>	Evaluate shifted Chebyshev polynomial of the first kind at a point.
<code>eval_sh_chebyu(n, x[, out])</code>	Evaluate shifted Chebyshev polynomial of the second kind at a point.
<code>eval_sh_jacobi(n, p, q, x[, out])</code>	Evaluate shifted Jacobi polynomial at a point.

`scipy.special.assoc_laguerre(x, n, k=0.0)`

Compute the generalized (associated) Laguerre polynomial of degree  $n$  and order  $k$ .

The polynomial  $L_n^{(k)}(x)$  is orthogonal over  $[0, \infty)$ , with weighting function  $\exp(-x) * x^{**k}$  with  $k > -1$ .

**Notes**

`assoc_laguerre` is a simple wrapper around `eval_genlaguerre`, with reversed argument order  $(x, n, k=0.0) \rightarrow (n, k, x)$ .

`scipy.special.eval_legendre(n, x, out=None) = <ufunc 'eval_legendre'>`

Evaluate Legendre polynomial at a point.

The Legendre polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$P_n(x) = {}_2F_1(-n, n + 1; 1; (1 - x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like

Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

**x** : array\_like

Points at which to evaluate the Legendre polynomial

**Returns**

**P** : ndarray

Values of the Legendre polynomial

See also:

**roots\_legendre**

roots and quadrature weights of Legendre polynomials

**legendre** Legendre polynomial object

**hyp2f1** Gauss hypergeometric function

**numpy.polynomial.legendre.Legendre**

Legendre series

`scipy.special.eval_chebyt(n, x, out=None) = <ufunc 'eval_chebyt'>`

Evaluate Chebyshev polynomial of the first kind at a point.

The Chebyshev polynomials of the first kind can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$T_n(x) = {}_2F_1(n, -n; 1/2; (1 - x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like  
Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

**x** : array\_like  
Points at which to evaluate the Chebyshev polynomial

**Returns** **T** : ndarray  
Values of the Chebyshev polynomial

See also:

**roots\_chebyt**

roots and quadrature weights of Chebyshev polynomials of the first kind

**chebyu** Chebyshev polynomial object

**eval\_chebyu**

evaluate Chebyshev polynomials of the second kind

**hyp2f1** Gauss hypergeometric function

*numpy.polynomial.chebyshev.Chebyshev*

Chebyshev series

**Notes**

This routine is numerically stable for  $x$  in  $[-1, 1]$  at least up to order 10000.

`scipy.special.eval_chebyu(n, x, out=None) = <ufunc 'eval_chebyu'>`

Evaluate Chebyshev polynomial of the second kind at a point.

The Chebyshev polynomials of the second kind can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$U_n(x) = (n+1) {}_2F_1(-n, n+2; 3/2; (1-x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like  
Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

**x** : array\_like  
Points at which to evaluate the Chebyshev polynomial

**Returns** **U** : ndarray  
Values of the Chebyshev polynomial

See also:

**roots\_chebyu**

roots and quadrature weights of Chebyshev polynomials of the second kind

**chebyu** Chebyshev polynomial object

**eval\_chebyt**

evaluate Chebyshev polynomials of the first kind

**hyp2f1** Gauss hypergeometric function

`scipy.special.eval_chebyc(n, x, out=None) = <ufunc 'eval_chebyc'>`

Evaluate Chebyshev polynomial of the first kind on  $[-2, 2]$  at a point.

These polynomials are defined as

$$S_n(x) = T_n(x/2)$$

where  $T_n$  is a Chebyshev polynomial of the first kind.

**Parameters** **n** : array\_like  
Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyt`.

**Returns** **x** : array\_like Points at which to evaluate the Chebyshev polynomial  
**C** : ndarray Values of the Chebyshev polynomial

See also:

**roots\_chebyc**

roots and quadrature weights of Chebyshev polynomials of the first kind on [-2, 2]

**chebyc** Chebyshev polynomial object

*numpy.polynomial.chebyshev.Chebyshev*

Chebyshev series

**eval\_chebyt**

evaluate Chebyshev polynomials of the first kind

`scipy.special.eval_chebys(n, x, out=None) = <ufunc 'eval_chebys'>`

Evaluate Chebyshev polynomial of the second kind on [-2, 2] at a point.

These polynomials are defined as

$$S_n(x) = U_n(x/2)$$

where  $U_n$  is a Chebyshev polynomial of the second kind.

**Parameters** **n** : array\_like

Degree of the polynomial. If not an integer, the result is determined via the relation to *eval\_chebyu*.

**x** : array\_like

**Returns**

**S** : ndarray

Points at which to evaluate the Chebyshev polynomial

Values of the Chebyshev polynomial

See also:

**roots\_chebys**

roots and quadrature weights of Chebyshev polynomials of the second kind on [-2, 2]

**chebys** Chebyshev polynomial object

**eval\_chebyu**

evaluate Chebyshev polynomials of the second kind

`scipy.special.eval_jacobi(n, alpha, beta, x, out=None) = <ufunc 'eval_jacobi'>`

Evaluate Jacobi polynomial at a point.

The Jacobi polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$P_n^{(\alpha, \beta)}(x) = \frac{(\alpha + 1)_n}{\Gamma(n + 1)} {}_2F_1(-n, 1 + \alpha + \beta + n; \alpha + 1; (1 - z)/2)$$

where  $(\cdot)_n$  is the Pochhammer symbol; see *poch*. When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like

Degree of the polynomial. If not an integer the result is determined via the relation to the Gauss hypergeometric function.

**alpha** : array\_like

Parameter

**beta** : array\_like

Parameter

**x** : array\_like

**Returns**

**P** : ndarray

Points at which to evaluate the polynomial

Values of the Jacobi polynomial

See also:

**jacobi** Jacobi polynomial object  
**hyp2f1** Gauss hypergeometric function

`scipy.special.eval_laguerre` ( $n, x, out=None$ ) = <ufunc 'eval\_laguerre'>  
 Evaluate Laguerre polynomial at a point.

The Laguerre polynomials can be defined via the confluent hypergeometric function  ${}_1F_1$  as

$$L_n(x) = {}_1F_1(-n, 1, x).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like  
 Degree of the polynomial. If not an integer the result is determined via the relation to the confluent hypergeometric function.  
**x** : array\_like  
 Points at which to evaluate the Laguerre polynomial  
**Returns** **L** : ndarray  
 Values of the Laguerre polynomial

See also:

**roots\_laguerre** roots and quadrature weights of Laguerre polynomials  
**laguerre** Laguerre polynomial object  
**numpy.polynomial.laguerre.Laguerre** Laguerre series  
**eval\_genlaguerre** evaluate generalized Laguerre polynomials

`scipy.special.eval_genlaguerre` ( $n, alpha, x, out=None$ ) = <ufunc 'eval\_genlaguerre'>  
 Evaluate generalized Laguerre polynomial at a point.

The generalized Laguerre polynomials can be defined via the confluent hypergeometric function  ${}_1F_1$  as

$$L_n^{(\alpha)}(x) = \binom{n+\alpha}{n} {}_1F_1(-n, \alpha+1, x).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . The Laguerre polynomials are the special case where  $\alpha = 0$ .

**Parameters** **n** : array\_like  
 Degree of the polynomial. If not an integer the result is determined via the relation to the confluent hypergeometric function.  
**alpha** : array\_like  
 Parameter; must have  $\alpha > -1$   
**x** : array\_like  
 Points at which to evaluate the generalized Laguerre polynomial  
**Returns** **L** : ndarray  
 Values of the generalized Laguerre polynomial

See also:

**roots\_genlaguerre** roots and quadrature weights of generalized Laguerre polynomials  
**genlaguerre** generalized Laguerre polynomial object

**hyp1f1** confluent hypergeometric function  
**eval\_laguerre**  
 evaluate Laguerre polynomials

`scipy.special.eval_hermite` (*n*, *x*, *out=None*) = <ufunc 'eval\_hermite'>  
 Evaluate physicist's Hermite polynomial at a point.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

$H_n$  is a polynomial of degree  $n$ .

**Parameters**    **n** : array\_like                      Degree of the polynomial  
                   **x** : array\_like                      Points at which to evaluate the Hermite polynomial  
**Returns**        **H** : ndarray                                      Values of the Hermite polynomial

See also:

**roots\_hermite**  
 roots and quadrature weights of physicist's Hermite polynomials  
**hermite**        physicist's Hermite polynomial object  
[numpy.polynomial.hermite.Hermite](#)  
 Physicist's Hermite series  
**eval\_hermitenorm**  
 evaluate Probabilist's Hermite polynomials

`scipy.special.eval_hermitenorm` (*n*, *x*, *out=None*) = <ufunc 'eval\_hermitenorm'>  
 Evaluate probabilist's (normalized) Hermite polynomial at a point.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$He_n$  is a polynomial of degree  $n$ .

**Parameters**    **n** : array\_like                      Degree of the polynomial  
                   **x** : array\_like                      Points at which to evaluate the Hermite polynomial  
**Returns**        **He** : ndarray                                      Values of the Hermite polynomial

See also:

**roots\_hermitenorm**  
 roots and quadrature weights of probabilist's Hermite polynomials  
**hermitenorm**  
 probabilist's Hermite polynomial object  
[numpy.polynomial.hermite\\_e.HermiteE](#)  
 Probabilist's Hermite series  
**eval\_hermite**  
 evaluate physicist's Hermite polynomials

`scipy.special.eval_gegenbauer` (*n*, *alpha*, *x*, *out=None*) = <ufunc 'eval\_gegenbauer'>  
 Evaluate Gegenbauer polynomial at a point.

The Gegenbauer polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$C_n^{(\alpha)} = \frac{(2\alpha)_n}{\Gamma(n+1)} {}_2F_1(-n, 2\alpha + n; \alpha + 1/2; (1-z)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like  
Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

**alpha** : array\_like  
Parameter

**x** : array\_like  
Points at which to evaluate the Gegenbauer polynomial

**Returns** **C** : ndarray  
Values of the Gegenbauer polynomial

See also:

**roots\_gegenbauer**

roots and quadrature weights of Gegenbauer polynomials

**gegenbauer** Gegenbauer polynomial object

**hyp2f1** Gauss hypergeometric function

`scipy.special.eval_sh_legendre` ( $n, x, out=None$ ) = <ufunc 'eval\_sh\_legendre'>

Evaluate shifted Legendre polynomial at a point.

These polynomials are defined as

$$P_n^*(x) = P_n(2x - 1)$$

where  $P_n$  is a Legendre polynomial.

**Parameters** **n** : array\_like  
Degree of the polynomial. If not an integer, the value is determined via the relation to `eval_legendre`.

**x** : array\_like  
Points at which to evaluate the shifted Legendre polynomial

**Returns** **P** : ndarray  
Values of the shifted Legendre polynomial

See also:

**roots\_sh\_legendre**

roots and quadrature weights of shifted Legendre polynomials

**sh\_legendre**

shifted Legendre polynomial object

**eval\_legendre**

evaluate Legendre polynomials

**numpy.polynomial.legendre.Legendre**

Legendre series

`scipy.special.eval_sh_chebyt` ( $n, x, out=None$ ) = <ufunc 'eval\_sh\_chebyt'>

Evaluate shifted Chebyshev polynomial of the first kind at a point.

These polynomials are defined as

$$T_n^*(x) = T_n(2x - 1)$$

where  $T_n$  is a Chebyshev polynomial of the first kind.

**Parameters** **n** : array\_like

Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyt`.

**Returns** `x` : array\_like  
**T** : ndarray Points at which to evaluate the shifted Chebyshev polynomial  
Values of the shifted Chebyshev polynomial

See also:

**roots\_sh\_chebyt**

roots and quadrature weights of shifted Chebyshev polynomials of the first kind

**sh\_chebyt** shifted Chebyshev polynomial object

**eval\_chebyt**

evaluate Chebyshev polynomials of the first kind

*numpy.polynomial.chebyshev.Chebyshev*

Chebyshev series

`scipy.special.eval_sh_chebyu(n, x, out=None) = <ufunc 'eval_sh_chebyu'>`

Evaluate shifted Chebyshev polynomial of the second kind at a point.

These polynomials are defined as

$$U_n^*(x) = U_n(2x - 1)$$

where  $U_n$  is a Chebyshev polynomial of the first kind.

**Parameters** `n` : array\_like

Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyu`.

`x` : array\_like

**Returns** `U` : ndarray Points at which to evaluate the shifted Chebyshev polynomial  
Values of the shifted Chebyshev polynomial

See also:

**roots\_sh\_chebyu**

roots and quadrature weights of shifted Chebychev polynomials of the second kind

**sh\_chebyu** shifted Chebyshev polynomial object

**eval\_chebyu**

evaluate Chebyshev polynomials of the second kind

`scipy.special.eval_sh_jacobi(n, p, q, x, out=None) = <ufunc 'eval_sh_jacobi'>`

Evaluate shifted Jacobi polynomial at a point.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q, q-1)}(2x-1),$$

where  $P_n^{(\cdot, \cdot)}$  is the n-th Jacobi polynomial.

**Parameters** `n` : int

Degree of the polynomial. If not an integer, the result is determined via the relation to `binom` and `eval_jacobi`.

`p` : float

Parameter

`q` : float

Parameter

**Returns** `G` : ndarray Values of the shifted Jacobi polynomial.

**See also:****roots\_sh\_jacobi**

roots and quadrature weights of shifted Jacobi polynomials

**sh\_jacobi** shifted Jacobi polynomial object**eval\_jacobi**

evaluate Jacobi polynomials

The following functions compute roots and quadrature weights for orthogonal polynomials:

<code>roots_legendre(n[, mu])</code>	Gauss-Legendre quadrature.
<code>roots_chebyt(n[, mu])</code>	Gauss-Chebyshev (first kind) quadrature.
<code>roots_chebyu(n[, mu])</code>	Gauss-Chebyshev (second kind) quadrature.
<code>roots_chebyc(n[, mu])</code>	Gauss-Chebyshev (first kind) quadrature.
<code>roots_chebys(n[, mu])</code>	Gauss-Chebyshev (second kind) quadrature.
<code>roots_jacobi(n, alpha, beta[, mu])</code>	Gauss-Jacobi quadrature.
<code>roots_laguerre(n[, mu])</code>	Gauss-Laguerre quadrature.
<code>roots_genlaguerre(n, alpha[, mu])</code>	Gauss-generalized Laguerre quadrature.
<code>roots_hermite(n[, mu])</code>	Gauss-Hermite (physicist's) quadrature.
<code>roots_hermitenorm(n[, mu])</code>	Gauss-Hermite (statistician's) quadrature.
<code>roots_gegenbauer(n, alpha[, mu])</code>	Gauss-Gegenbauer quadrature.
<code>roots_sh_legendre(n[, mu])</code>	Gauss-Legendre (shifted) quadrature.
<code>roots_sh_chebyt(n[, mu])</code>	Gauss-Chebyshev (first kind, shifted) quadrature.
<code>roots_sh_chebyu(n[, mu])</code>	Gauss-Chebyshev (second kind, shifted) quadrature.
<code>roots_sh_jacobi(n, p1, q1[, mu])</code>	Gauss-Jacobi (shifted) quadrature.

`scipy.special.roots_legendre` ( $n, mu=False$ )

Gauss-Legendre quadrature.

Computes the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the  $n$ -th degree Legendre polynomial  $P_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = 1.0$ .

**Parameters**

- n** : int  
quadrature order
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`, `numpy.polynomial.legendre.leggauss`

`scipy.special.roots_chebyt` ( $n, mu=False$ )

Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree Chebyshev polynomial of the first kind,  $T_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = 1/\sqrt{1 - x^2}$ .

**Parameters**

- n** : int  
quadrature order

**Returns**

<b>mu</b> : bool, optional	If True, return the sum of the weights, optional.
<b>x</b> : ndarray	Sample points
<b>w</b> : ndarray	Weights
<b>mu</b> : float	Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`, `numpy.polynomial.chebyshev.chebgauss`

`scipy.special.roots_chebyu` (*n*, *mu=False*)

Gauss-Chebyshev (second kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the *n*-th degree Chebyshev polynomial of the second kind,  $U_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = \sqrt{1 - x^2}$ .

**Parameters**

<b>n</b> : int	quadrature order
<b>mu</b> : bool, optional	If True, return the sum of the weights, optional.

**Returns**

<b>x</b> : ndarray	Sample points
<b>w</b> : ndarray	Weights
<b>mu</b> : float	Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_chebyc` (*n*, *mu=False*)

Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the *n*-th degree Chebyshev polynomial of the first kind,  $C_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-2, 2]$  with weight function  $f(x) = 1/\sqrt{1 - (x/2)^2}$ .

**Parameters**

<b>n</b> : int	quadrature order
<b>mu</b> : bool, optional	If True, return the sum of the weights, optional.

**Returns**

<b>x</b> : ndarray	Sample points
<b>w</b> : ndarray	Weights
<b>mu</b> : float	Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_chebys` (*n*, *mu=False*)

Gauss-Chebyshev (second kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree Chebyshev polynomial of the second kind,  $S_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-2, 2]$  with weight function  $f(x) = \sqrt{1 - (x/2)^2}$ .

**Parameters**

- n** : int  
quadrature order
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_jacobi` ( $n$ ,  $alpha$ ,  $beta$ ,  $mu=False$ )

Gauss-Jacobi quadrature.

Computes the sample points and weights for Gauss-Jacobi quadrature. The sample points are the roots of the  $n$ -th degree Jacobi polynomial,  $P_n^{\alpha, \beta}(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = (1 - x)^\alpha(1 + x)^\beta$ .

**Parameters**

- n** : int  
quadrature order
- alpha** : float  
alpha must be  $> -1$
- beta** : float  
beta must be  $> 0$
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_laguerre` ( $n$ ,  $mu=False$ )

Gauss-Laguerre quadrature.

Computes the sample points and weights for Gauss-Laguerre quadrature. The sample points are the roots of the  $n$ -th degree Laguerre polynomial,  $L_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, \infty]$  with weight function  $f(x) = e^{-x}$ .

**Parameters**

- n** : int  
quadrature order
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float

Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`, `numpy.polynomial.laguerre.laggauss`

`scipy.special.roots_genlaguerre` (*n*, *alpha*, *mu=False*)

Gauss-generalized Laguerre quadrature.

Computes the sample points and weights for Gauss-generalized Laguerre quadrature. The sample points are the roots of the *n*-th degree generalized Laguerre polynomial,  $L_n^\alpha(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, \infty]$  with weight function  $f(x) = x^\alpha e^{-x}$ .

<b>Parameters</b>	<b>n</b> : int	quadrature order
	<b>alpha</b> : float	alpha must be > -1
<b>Returns</b>	<b>mu</b> : bool, optional	If True, return the sum of the weights, optional.
	<b>x</b> : ndarray	Sample points
	<b>w</b> : ndarray	Weights
	<b>mu</b> : float	Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_hermite` (*n*, *mu=False*)

Gauss-Hermite (physicst's) quadrature.

Computes the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the *n*-th degree Hermite polynomial,  $H_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-\infty, \infty]$  with weight function  $f(x) = e^{-x^2}$ .

<b>Parameters</b>	<b>n</b> : int	quadrature order
	<b>mu</b> : bool, optional	If True, return the sum of the weights, optional.
<b>Returns</b>	<b>x</b> : ndarray	Sample points
	<b>w</b> : ndarray	Weights
	<b>mu</b> : float	Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`, `numpy.polynomial.hermite.hermgauss`, `roots_hermitenorm`

**Notes**

For small *n* up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.

For  $n$  larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerically stable manner. The algorithm has linear runtime making computation for very large  $n$  (several thousand or more) feasible.

### References

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_sh_legendre` ( $n$ ,  $mu=False$ )

Gauss-Legendre (shifted) quadrature.

Computes the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the  $n$ -th degree shifted Legendre polynomial  $P_n^*(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, 1]$  with weight function  $f(x) = 1.0$ .

<b>Parameters</b>	<b>n</b> : int	quadrature order
	<b>mu</b> : bool, optional	If True, return the sum of the weights, optional.
<b>Returns</b>	<b>x</b> : ndarray	Sample points
	<b>w</b> : ndarray	Weights
	<b>mu</b> : float	Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_sh_chebyt` ( $n$ ,  $mu=False$ )

Gauss-Chebyshev (first kind, shifted) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree shifted Chebyshev polynomial of the first kind,  $T_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, 1]$  with weight function  $f(x) = 1/\sqrt{x - x^2}$ .

<b>Parameters</b>	<b>n</b> : int	quadrature order
	<b>mu</b> : bool, optional	If True, return the sum of the weights, optional.
<b>Returns</b>	<b>x</b> : ndarray	Sample points
	<b>w</b> : ndarray	Weights
	<b>mu</b> : float	Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_sh_chebyu` ( $n$ ,  $mu=False$ )

Gauss-Chebyshev (second kind, shifted) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree shifted Chebyshev polynomial of the second kind,  $U_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, 1]$  with weight function  $f(x) = \sqrt{x - x^2}$ .

<b>Parameters</b>	<b>n</b> : int	quadrature order
	<b>mu</b> : bool, optional	If True, return the sum of the weights, optional.
<b>Returns</b>	<b>x</b> : ndarray	Sample points
	<b>w</b> : ndarray	

**mu** : float  
Weights  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_sh_jacobi` (*n*, *p1*, *q1*, *mu=False*)  
Gauss-Jacobi (shifted) quadrature.

Computes the sample points and weights for Gauss-Jacobi (shifted) quadrature. The sample points are the roots of the *n*-th degree shifted Jacobi polynomial,  $G_n^{p,q}(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, 1]$  with weight function  $f(x) = (1 - x)^{p-q}x^{q-1}$

**Parameters**

- n** : int  
quadrature order
- p1** : float  
(p1 - q1) must be > -1
- q1** : float  
q1 must be > 0
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

The functions below, in turn, return the polynomial coefficients in `orthopoly1d` objects, which function similarly as `numpy.poly1d`. The `orthopoly1d` class also has an attribute `weights` which returns the roots, weights, and total weights for the appropriate form of Gaussian quadrature. These are returned in an  $n \times 3$  array with roots in the first column, weights in the second column, and total weights in the final column. Note that `orthopoly1d` objects are converted to `poly1d` when doing arithmetic, and lose information of the original orthogonal polynomial.

<code>legendre</code> ( <i>n</i> [, <i>monic</i> ])	Legendre polynomial.
<code>chebyt</code> ( <i>n</i> [, <i>monic</i> ])	Chebyshev polynomial of the first kind.
<code>chebyu</code> ( <i>n</i> [, <i>monic</i> ])	Chebyshev polynomial of the second kind.
<code>chebyc</code> ( <i>n</i> [, <i>monic</i> ])	Chebyshev polynomial of the first kind on $[-2, 2]$ .
<code>chebys</code> ( <i>n</i> [, <i>monic</i> ])	Chebyshev polynomial of the second kind on $[-2, 2]$ .
<code>jacobi</code> ( <i>n</i> , <i>alpha</i> , <i>beta</i> [, <i>monic</i> ])	Jacobi polynomial.
<code>laguerre</code> ( <i>n</i> [, <i>monic</i> ])	Laguerre polynomial.
<code>genlaguerre</code> ( <i>n</i> , <i>alpha</i> [, <i>monic</i> ])	Generalized (associated) Laguerre polynomial.
<code>hermite</code> ( <i>n</i> [, <i>monic</i> ])	Physicist's Hermite polynomial.

`scipy.special.legendre` (*n*, *monic=False*)

Legendre polynomial.

Defined to be the solution of

$$\frac{d}{dx} \left[ (1 - x^2) \frac{d}{dx} P_n(x) \right] + n(n + 1)P_n(x) = 0;$$

$P_n(x)$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **P** : orthopoly1d  
Legendre polynomial.

**Notes**

The polynomials  $P_n$  are orthogonal over  $[-1, 1]$  with weight function 1.

**Examples**

Generate the 3rd-order Legendre polynomial  $1/2*(5x^3 + 0x^2 - 3x + 0)$ :

```
>>> from scipy.special import legendre
>>> legendre(3)
poly1d([ 2.5,  0. , -1.5,  0. ])
```

`scipy.special.chebyt` ( $n$ , *monic=False*)

Chebyshev polynomial of the first kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} T_n - x \frac{d}{dx} T_n + n^2 T_n = 0;$$

$T_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **T** : orthopoly1d  
Chebyshev polynomial of the first kind.

**See also:**

**chebyu** Chebyshev polynomial of the second kind.

**Notes**

The polynomials  $T_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{-1/2}$ .

`scipy.special.chebyu` ( $n$ , *monic=False*)

Chebyshev polynomial of the second kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} U_n - 3x \frac{d}{dx} U_n + n(n + 2)U_n = 0;$$

$U_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : int

**Returns** **U** : orthopoly1d  
 Degree of the polynomial.  
**monic** : bool, optional  
 If *True*, scale the leading coefficient to be 1. Default is *False*.  
 Chebyshev polynomial of the second kind.

**See also:**

**chebyt** Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $U_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{1/2}$ .

`scipy.special.chebyc` ( $n$ , *monic=False*)  
 Chebyshev polynomial of the first kind on  $[-2, 2]$ .

Defined as  $C_n(x) = 2T_n(x/2)$ , where  $T_n$  is the  $n$ th Chebychev polynomial of the first kind.

**Parameters** **n** : int  
 Degree of the polynomial.  
**monic** : bool, optional  
 If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns** **C** : orthopoly1d  
 Chebyshev polynomial of the first kind on  $[-2, 2]$ .

**See also:**

**chebyt** Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $C_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $1/\sqrt{1 - (x/2)^2}$ .

**References**

[R435]

`scipy.special.chebys` ( $n$ , *monic=False*)  
 Chebyshev polynomial of the second kind on  $[-2, 2]$ .

Defined as  $S_n(x) = U_n(x/2)$  where  $U_n$  is the  $n$ th Chebychev polynomial of the second kind.

**Parameters** **n** : int  
 Degree of the polynomial.  
**monic** : bool, optional  
 If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns** **S** : orthopoly1d  
 Chebyshev polynomial of the second kind on  $[-2, 2]$ .

**See also:**

**chebyu** Chebyshev polynomial of the second kind

**Notes**

The polynomials  $S_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $\sqrt{1 - (x/2)^2}$ .

**References**

[R436]

`scipy.special.jacobi` (*n*, *alpha*, *beta*, *monic=False*)

Jacobi polynomial.

Defined to be the solution of

$$(1-x^2)\frac{d^2}{dx^2}P_n^{(\alpha,\beta)} + (\beta - \alpha - (\alpha + \beta + 2)x)\frac{d}{dx}P_n^{(\alpha,\beta)} + n(n + \alpha + \beta + 1)P_n^{(\alpha,\beta)} = 0$$

for  $\alpha, \beta > -1$ ;  $P_n^{(\alpha,\beta)}$  is a polynomial of degree  $n$ .

**Parameters**

- n** : int  
Degree of the polynomial.
- alpha** : float  
Parameter, must be greater than -1.
- beta** : float  
Parameter, must be greater than -1.
- monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**P** : orthopoly1d  
Jacobi polynomial.

**Notes**

For fixed  $\alpha, \beta$ , the polynomials  $P_n^{(\alpha,\beta)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1-x)^\alpha(1+x)^\beta$ .

`scipy.special.laguerre` (*n*, *monic=False*)

Laguerre polynomial.

Defined to be the solution of

$$x\frac{d^2}{dx^2}L_n + (1-x)\frac{d}{dx}L_n + nL_n = 0;$$

$L_n$  is a polynomial of degree  $n$ .

**Parameters**

- n** : int  
Degree of the polynomial.
- monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**L** : orthopoly1d  
Laguerre Polynomial.

**Notes**

The polynomials  $L_n$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x}$ .

`scipy.special.genlaguerre` (*n*, *alpha*, *monic=False*)

Generalized (associated) Laguerre polynomial.

Defined to be the solution of

$$x\frac{d^2}{dx^2}L_n^{(\alpha)} + (\alpha + 1 - x)\frac{d}{dx}L_n^{(\alpha)} + nL_n^{(\alpha)} = 0,$$

where  $\alpha > -1$ ;  $L_n^{(\alpha)}$  is a polynomial of degree  $n$ .

**Parameters**

- n** : int  
Degree of the polynomial.
- alpha** : float  
Parameter, must be greater than -1.
- monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**L** : orthopoly1d

Generalized Laguerre polynomial.

**See also:**

**laguerre** Laguerre polynomial.

**Notes**

For fixed  $\alpha$ , the polynomials  $L_n^{(\alpha)}$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x}x^\alpha$ .

The Laguerre polynomials are the special case where  $\alpha = 0$ .

`scipy.special.hermite` ( $n$ , *monic=False*)

Physicist's Hermite polynomial.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

$H_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : int

Degree of the polynomial.

**monic** : bool, optional

**Returns** **H** : orthopoly1d If *True*, scale the leading coefficient to be 1. Default is *False*.  
Hermite polynomial.

**Notes**

The polynomials  $H_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2}$ .

`scipy.special.hermite` ( $n$ , *monic=False*)

Normalized (probabilist's) Hermite polynomial.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$He_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : int

Degree of the polynomial.

**monic** : bool, optional

**Returns** **He** : orthopoly1d If *True*, scale the leading coefficient to be 1. Default is *False*.  
Hermite polynomial.

**Notes**

The polynomials  $He_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2/2}$ .

`scipy.special.gegenbauer` ( $n$ , *alpha*, *monic=False*)

Gegenbauer (ultraspherical) polynomial.

Defined to be the solution of

$$(1-x^2) \frac{d^2}{dx^2} C_n^{(\alpha)} - (2\alpha+1)x \frac{d}{dx} C_n^{(\alpha)} + n(n+2\alpha) C_n^{(\alpha)} = 0$$

for  $\alpha > -1/2$ ;  $C_n^{(\alpha)}$  is a polynomial of degree  $n$ .

**Parameters** **n** : int

**Returns** **C** : orthopoly1d  
 Degree of the polynomial.  
**monic** : bool, optional  
 If *True*, scale the leading coefficient to be 1. Default is *False*.  
 Gegenbauer polynomial.

**Notes**

The polynomials  $C_n^{(\alpha)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{(\alpha-1/2)}$ .

`scipy.special.sh_legendre` (*n*, *monic=False*)  
 Shifted Legendre polynomial.

Defined as  $P_n^*(x) = P_n(2x - 1)$  for  $P_n$  the *n*th Legendre polynomial.

**Parameters** **n** : int  
 Degree of the polynomial.  
**monic** : bool, optional  
 If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns** **P** : orthopoly1d  
 Shifted Legendre polynomial.

**Notes**

The polynomials  $P_n^*$  are orthogonal over  $[0, 1]$  with weight function 1.

`scipy.special.sh_chebyt` (*n*, *monic=False*)  
 Shifted Chebyshev polynomial of the first kind.

Defined as  $T_n^*(x) = T_n(2x - 1)$  for  $T_n$  the *n*th Chebyshev polynomial of the first kind.

**Parameters** **n** : int  
 Degree of the polynomial.  
**monic** : bool, optional  
 If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns** **T** : orthopoly1d  
 Shifted Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $T_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{-1/2}$ .

`scipy.special.sh_chebyu` (*n*, *monic=False*)  
 Shifted Chebyshev polynomial of the second kind.

Defined as  $U_n^*(x) = U_n(2x - 1)$  for  $U_n$  the *n*th Chebyshev polynomial of the second kind.

**Parameters** **n** : int  
 Degree of the polynomial.  
**monic** : bool, optional  
 If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns** **U** : orthopoly1d  
 Shifted Chebyshev polynomial of the second kind.

**Notes**

The polynomials  $U_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{1/2}$ .

`scipy.special.sh_jacobi` (*n*, *p*, *q*, *monic=False*)  
 Shifted Jacobi polynomial.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q, q-1)}(2x-1),$$

where  $P_n^{(\cdot, \cdot)}$  is the  $n$ th Jacobi polynomial.

**Parameters**

- n** : int  
Degree of the polynomial.
- p** : float  
Parameter, must have  $p > q - 1$ .
- q** : float  
Parameter, must be greater than 0.
- monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

- G** : orthopoly1d  
Shifted Jacobi polynomial.

#### Notes

For fixed  $p, q$ , the polynomials  $G_n^{(p,q)}$  are orthogonal over  $[0, 1]$  with weight function  $(1-x)^{p-q}x^{q-1}$ .

**Warning:** Computing values of high-order polynomials (around `order > 20`) using polynomial coefficients is numerically unstable. To evaluate polynomial values, the `eval_*` functions should be used instead.

## Hypergeometric Functions

<code>hyp2f1(a, b, c, z)</code>	Gauss hypergeometric function 2F1(a, b; c; z)
<code>hyp1f1(a, b, x)</code>	Confluent hypergeometric function 1F1(a, b; x)
<code>hyperu(a, b, x)</code>	Confluent hypergeometric function U(a, b, x) of the second kind
<code>hyp0f1(v, x)</code>	Confluent hypergeometric limit function 0F1.
<code>hyp2f0(a, b, x, type)</code>	Hypergeometric function 2F0 in y and an error estimate
<code>hyp1f2(a, b, c, x)</code>	Hypergeometric function 1F2 and error estimate
<code>hyp3f0(a, b, c, x)</code>	Hypergeometric function 3F0 in y and an error estimate

`scipy.special.hyp2f1(a, b, c, z) = <ufunc 'hyp2f1'>`

Gauss hypergeometric function 2F1(a, b; c; z)

**Parameters**

- a, b, c** : array\_like  
Arguments, should be real-valued.
- z** : array\_like  
Argument, real or complex.

**Returns**

- hyp2f1** : scalar or ndarray  
The values of the gaussian hypergeometric function.

**See also:**

**hyp0f1** confluent hypergeometric limit function.  
**hyp1f1** Kummer's (confluent hypergeometric) function.

**Notes**

This function is defined for  $|z| < 1$  as

$$\text{hyp2f1}(a, b, c, z) = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(c)_n} \frac{z^n}{n!},$$

and defined on the rest of the complex  $z$ -plane by analytic continuation. Here  $(\cdot)_n$  is the Pochhammer symbol; see *poch*. When  $n$  is an integer the result is a polynomial of degree  $n$ .

The implementation for complex values of  $z$  is described in [R488].

**References**

[R488], [R489], [R490]

`scipy.special.hyp1f1(a, b, x) = <ufunc 'hyp1f1'>`  
 Confluent hypergeometric function 1F1(a, b; x)

`scipy.special.hyperu(a, b, x) = <ufunc 'hyperu'>`  
 Confluent hypergeometric function U(a, b, x) of the second kind

`scipy.special.hyp0f1(v, x) = <ufunc 'hyp0f1'>`  
 Confluent hypergeometric limit function 0F1.

**Parameters** `v, z` : array\_like  
 Input values.  
**Returns** `hyp0f1` : ndarray  
 The confluent hypergeometric limit function.

**Notes**

This function is defined as:

$${}_0F_1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}.$$

It's also the limit as  $q \rightarrow \infty$  of  ${}_1F_1(q; v; z/q)$ , and satisfies the differential equation  $f''(z) + v f'(z) = f(z)$ .

`scipy.special.hyp2f0(a, b, x, type) = <ufunc 'hyp2f0'>`  
 Hypergeometric function 2F0 in  $y$  and an error estimate

The parameter *type* determines a convergence factor and can be either 1 or 2.

**Returns** `y` Value of the function  
`err` Error estimate

`scipy.special.hyp1f2(a, b, c, x) = <ufunc 'hyp1f2'>`  
 Hypergeometric function 1F2 and error estimate

**Returns** `y` Value of the function  
`err` Error estimate

`scipy.special.hyp3f0(a, b, c, x) = <ufunc 'hyp3f0'>`  
 Hypergeometric function 3F0 in  $y$  and an error estimate

**Returns** `y` Value of the function  
`err` Error estimate

## Parabolic Cylinder Functions

<code>pbdv(v, x)</code>	Parabolic cylinder function D
<code>pbvv(v, x)</code>	Parabolic cylinder function V
<code>pbwa(a, x)</code>	Parabolic cylinder function W.

`scipy.special.pbdv(v, x) = <ufunc 'pbdv'>`

Parabolic cylinder function D

Returns (d, dp) the parabolic cylinder function  $Dv(x)$  in d and the derivative,  $Dv'(x)$  in dp.

**Returns**

d	Value of the function
dp	Value of the derivative vs x

`scipy.special.pbvv(v, x) = <ufunc 'pbvv'>`

Parabolic cylinder function V

Returns the parabolic cylinder function  $Vv(x)$  in v and the derivative,  $Vv'(x)$  in vp.

**Returns**

v	Value of the function
vp	Value of the derivative vs x

`scipy.special.pbwa(a, x) = <ufunc 'pbwa'>`

Parabolic cylinder function W.

The function is a particular solution to the differential equation

$$y'' + \left(\frac{1}{4}x^2 - a\right)y = 0,$$

for a full definition see section 12.14 in [R559].

**Parameters**

<b>a</b> : array_like	Real parameter
<b>x</b> : array_like	Real argument

**Returns**

<b>w</b> : scalar or ndarray	Value of the function
<b>wp</b> : scalar or ndarray	Value of the derivative in x

### Notes

The function is a wrapper for a Fortran routine by Zhang and Jin [R560]. The implementation is accurate only for  $|a|, |x| < 5$  and returns NaN outside that range.

<code>pbvv_seq(v, x)</code>	Parabolic cylinder functions $Vv(x)$ and derivatives.
<code>pbdn_seq(n, z)</code>	Parabolic cylinder functions $Dn(z)$ and derivatives.

`scipy.special.pbdv_seq(v, x)`

Parabolic cylinder functions  $Dv(x)$  and derivatives.

**Parameters**

- v** : float  
Order of the parabolic cylinder function
- x** : float  
Value at which to evaluate the function and derivatives

**Returns**

- dv** : ndarray  
Values of  $D_{vi}(x)$ , for  $vi=v-int(v)$ ,  $vi=1+v-int(v)$ , ...,  $vi=v$ .
- dp** : ndarray  
Derivatives  $D_{vi}'(x)$ , for  $vi=v-int(v)$ ,  $vi=1+v-int(v)$ , ...,  $vi=v$ .

**Mathieu and Related Functions**

---

<code>mathieu_a(m, q)</code>	Characteristic value of even Mathieu functions
<code>mathieu_b(m, q)</code>	Characteristic value of odd Mathieu functions

---

`scipy.special.mathieu_a(m, q) = <ufunc 'mathieu_a'>`

Characteristic value of even Mathieu functions

Returns the characteristic value for the even solution,  $ce_m(z, q)$ , of Mathieu's equation.

`scipy.special.mathieu_b(m, q) = <ufunc 'mathieu_b'>`

Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution,  $se_m(z, q)$ , of Mathieu's equation.

These are not universal functions:

<code>mathieu_even_coef(m, q)</code>	Fourier coefficients for even Mathieu and modified Mathieu functions.
<code>mathieu_odd_coef(m, q)</code>	Fourier coefficients for even Mathieu and modified Mathieu functions.

`scipy.special.mathieu_even_coef(m, q)`

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

$$ce_{2n}(z, q) = \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz$$

$$ce_{2n+1}(z, q) = \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k+1)z$$

This function returns the coefficients  $A_{(2n)}^{(2k)}$  for even input  $m=2n$ , and the coefficients  $A_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

**Parameters** **m** : int  
Order of Mathieu functions. Must be non-negative.

**q** : float (>=0)  
Parameter of Mathieu functions. Must be non-negative.

**Returns** **Ak** : ndarray  
Even or odd Fourier coefficients, corresponding to even or odd m.

### References

[R542], [R543]

`scipy.special.mathieu_odd_coef(m, q)`

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

$$se_{2n+1}(z, q) = \sum_{k=0}^{\infty} B_{(2n+1)}^{(2k+1)} \sin(2k+1)z$$

$$se_{2n+2}(z, q) = \sum_{k=0}^{\infty} B_{(2n+2)}^{(2k+2)} \sin(2k+2)z$$

This function returns the coefficients  $B_{(2n+2)}^{(2k+2)}$  for even input  $m=2n+2$ , and the coefficients  $B_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

**Parameters** **m** : int  
Order of Mathieu functions. Must be non-negative.

**q** : float (>=0)  
Parameter of Mathieu functions. Must be non-negative.

**Returns** **Bk** : ndarray  
Even or odd Fourier coefficients, corresponding to even or odd m.

**References**

[R544]

The following return both function and first derivative:

<code>mathieu_cem(m, q, x)</code>	Even Mathieu function and its derivative
<code>mathieu_sem(m, q, x)</code>	Odd Mathieu function and its derivative
<code>mathieu_modcem1(m, q, x)</code>	Even modified Mathieu function of the first kind and its derivative
<code>mathieu_modcem2(m, q, x)</code>	Even modified Mathieu function of the second kind and its derivative
<code>mathieu_modsem1(m, q, x)</code>	Odd modified Mathieu function of the first kind and its derivative
<code>mathieu_modsem2(m, q, x)</code>	Odd modified Mathieu function of the second kind and its derivative

`scipy.special.mathieu_cem(m, q, x) = <ufunc 'mathieu_cem'>`

Even Mathieu function and its derivative

Returns the even Mathieu function,  $ce_m(x, q)$ , of order  $m$  and parameter  $q$  evaluated at  $x$  (given in degrees). Also returns the derivative with respect to  $x$  of  $ce_m(x, q)$

<b>Parameters</b>	<b>m</b>	Order of the function
	<b>q</b>	Parameter of the function
	<b>x</b>	Argument of the function, <i>given in degrees, not radians</i>
<b>Returns</b>	<b>y</b>	Value of the function
	<b>yp</b>	Value of the derivative vs $x$

`scipy.special.mathieu_sem(m, q, x) = <ufunc 'mathieu_sem'>`

Odd Mathieu function and its derivative

Returns the odd Mathieu function,  $se_m(x, q)$ , of order  $m$  and parameter  $q$  evaluated at  $x$  (given in degrees). Also returns the derivative with respect to  $x$  of  $se_m(x, q)$ .

<b>Parameters</b>	<b>m</b>	Order of the function
	<b>q</b>	Parameter of the function
	<b>x</b>	Argument of the function, <i>given in degrees, not radians</i> .
<b>Returns</b>	<b>y</b>	Value of the function
	<b>yp</b>	Value of the derivative vs $x$

`scipy.special.mathieu_modcem1(m, q, x) = <ufunc 'mathieu_modcem1'>`

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind,  $Mc1m(x, q)$ , and its derivative at  $x$  for order  $m$  and parameter  $q$ .

<b>Returns</b>	<b>y</b>	Value of the function
----------------	----------	-----------------------

yp  
Value of the derivative vs x

`scipy.special.mathieu_modcem2(m, q, x) = <ufunc 'mathieu_modcem2'>`

Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind,  $Mc2m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns** y  
Value of the function  
yp  
Value of the derivative vs x

`scipy.special.mathieu_modsem1(m, q, x) = <ufunc 'mathieu_modsem1'>`

Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind,  $Ms1m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns** y  
Value of the function  
yp  
Value of the derivative vs x

`scipy.special.mathieu_modsem2(m, q, x) = <ufunc 'mathieu_modsem2'>`

Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind,  $Ms2m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns** y  
Value of the function  
yp  
Value of the derivative vs x

## Spheroidal Wave Functions

<code>pro_ang1(m, n, c, x)</code>	Prolate spheroidal angular function of the first kind and its derivative
<code>pro_rad1(m, n, c, x)</code>	Prolate spheroidal radial function of the first kind and its derivative
<code>pro_rad2(m, n, c, x)</code>	Prolate spheroidal radial function of the second kind and its derivative
<code>obl_ang1(m, n, c, x)</code>	Oblate spheroidal angular function of the first kind and its derivative
<code>obl_rad1(m, n, c, x)</code>	Oblate spheroidal radial function of the first kind and its derivative
<code>obl_rad2(m, n, c, x)</code>	Oblate spheroidal radial function of the second kind and its derivative.
<code>pro_cv(m, n, c)</code>	Characteristic value of prolate spheroidal function
<code>obl_cv(m, n, c)</code>	Characteristic value of oblate spheroidal function
<code>pro_cv_seq(m, n, c)</code>	Characteristic values for prolate spheroidal wave functions.
<code>obl_cv_seq(m, n, c)</code>	Characteristic values for oblate spheroidal wave functions.

`scipy.special.pro_ang1(m, n, c, x) = <ufunc 'pro_ang1'>`

Prolate spheroidal angular function of the first kind and its derivative

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

s	Value of the function
sp	Value of the derivative vs x

`scipy.special.pro_rad1(m, n, c, x) = <ufunc 'pro_rad1'>`

Prolate spheroidal radial function of the first kind and its derivative

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

s	Value of the function
sp	Value of the derivative vs x

`scipy.special.pro_rad2(m, n, c, x) = <ufunc 'pro_rad2'>`

Prolate spheroidal radial function of the second kind and its derivative

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

s	Value of the function
sp	Value of the derivative vs x

`scipy.special.obl_ang1(m, n, c, x) = <ufunc 'obl_ang1'>`

Oblate spheroidal angular function of the first kind and its derivative

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

s	Value of the function
sp	Value of the derivative vs x

`scipy.special.obl_rad1(m, n, c, x) = <ufunc 'obl_rad1'>`

Oblate spheroidal radial function of the first kind and its derivative

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

s	Value of the function
sp	Value of the derivative vs x

`scipy.special.obl_rad2(m, n, c, x) = <ufunc 'obl_rad2'>`

Oblate spheroidal radial function of the second kind and its derivative.

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

s	
---	--

Value of the function  
 sp Value of the derivative vs x

`scipy.special.pro_cv(m, n, c) = <ufunc 'pro_cv'>`

Characteristic value of prolate spheroidal function

Computes the characteristic value of prolate spheroidal wave functions of order  $m, n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

`scipy.special.obl_cv(m, n, c) = <ufunc 'obl_cv'>`

Characteristic value of oblate spheroidal function

Computes the characteristic value of oblate spheroidal wave functions of order  $m, n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

`scipy.special.pro_cv_seq(m, n, c)`

Characteristic values for prolate spheroidal wave functions.

Compute a sequence of characteristic values for the prolate spheroidal wave functions for mode  $m$  and  $n' = m..n$  and spheroidal parameter  $c$ .

**References**

[R561]

`scipy.special.obl_cv_seq(m, n, c)`

Characteristic values for oblate spheroidal wave functions.

Compute a sequence of characteristic values for the oblate spheroidal wave functions for mode  $m$  and  $n' = m..n$  and spheroidal parameter  $c$ .

**References**

[R555]

## Kelvin Functions

<code>kelvin(x)</code>	Kelvin functions as complex numbers
<code>kelvin_zeros(nt)</code>	Compute nt zeros of all Kelvin functions.
<code>ber(x)</code>	Kelvin function <i>ber</i> .
<code>bei(x)</code>	Kelvin function <i>bei</i>
<code>berp(x)</code>	Derivative of the Kelvin function <i>ber</i>
<code>beip(x)</code>	Derivative of the Kelvin function <i>bei</i>
<code>ker(x)</code>	Kelvin function <i>ker</i>
<code>kei(x)</code>	Kelvin function <i>ker</i>
<code>kerp(x)</code>	Derivative of the Kelvin function <i>ker</i>
<code>keip(x)</code>	Derivative of the Kelvin function <i>kei</i>

`scipy.special.kelvin(x) = <ufunc 'kelvin'>`

Kelvin functions as complex numbers

**Returns** Be, Ke, Bep, Kep

The tuple (Be, Ke, Bep, Kep) contains complex numbers representing the real and imaginary Kelvin functions and their derivatives evaluated at *x*. For example, `kelvin(x)[0].real = ber x` and `kelvin(x)[0].imag = bei x` with similar relationships for *ker* and *kei*.

`scipy.special.kelvin_zeros(nt)`

Compute nt zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length nt. The tuple contains the arrays of zeros of (*ber*, *bei*, *ker*, *kei*, *ber'*, *bei'*, *ker'*, *kei'*).

### References

[R520]

`scipy.special.ber(x) = <ufunc 'ber'>`

Kelvin function *ber*.

`scipy.special.bei(x) = <ufunc 'bei'>`

Kelvin function *bei*

`scipy.special.berp(x) = <ufunc 'berp'>`

## Combinatorics

<code>comb(N, k[, exact, repetition])</code>	The number of combinations of N things taken k at a time.
<code>perm(N, k[, exact])</code>	Permutations of N things taken k at a time, i.e., k-permutations of N.

`scipy.special.comb(N, k, exact=False, repetition=False)`

The number of combinations of N things taken k at a time.

This is often expressed as “N choose k”.

<b>Parameters</b>	<b>N</b> : int, ndarray Number of things.
	<b>k</b> : int, ndarray Number of elements taken.
	<b>exact</b> : bool, optional If <i>exact</i> is False, then floating point precision is used, otherwise exact long integer is computed.
	<b>repetition</b> : bool, optional If <i>repetition</i> is True, then the number of combinations with repetition is computed.
<b>Returns</b>	<b>val</b> : int, float, ndarray The total number of combinations.

### See also:

**binom** Binomial coefficient ufunc

### Notes

- Array arguments accepted only for `exact=False` case.
- If  $k > N$ ,  $N < 0$ , or  $k < 0$ , then a 0 is returned.

### Examples

```
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([ 120.,  210.])
>>> comb(10, 3, exact=True)
120L
>>> comb(10, 3, exact=True, repetition=True)
220L
```

`scipy.special.perm(N, k, exact=False)`

Permutations of N things taken k at a time, i.e., k-permutations of N.

It's also known as “partial permutations”.

<b>Parameters</b>	<b>N</b> : int, ndarray Number of things.
	<b>k</b> : int, ndarray Number of elements taken.

**exact** : bool, optional  
 If *exact* is False, then floating point precision is used, otherwise exact long integer is computed.

**Returns** **val** : int, ndarray  
 The number of k-permutations of N.

**Notes**

- Array arguments accepted only for exact=False case.
- If  $k > N$ ,  $N < 0$ , or  $k < 0$ , then a 0 is returned.

**Examples**

```
>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([ 720., 5040.])
>>> perm(10, 3, exact=True)
720
```

**Lambert W and Related Functions**

<code>lambertw(z[, k, tol])</code>	Lambert W function.
<code>wrightomega(z[, out])</code>	Wright Omega function.

**Other Special Functions**

<code>agm(a, b)</code>	Compute the arithmetic-geometric mean of <i>a</i> and <i>b</i> .
<code>bernoulli(n)</code>	Bernoulli numbers B <sub>0</sub> ..B <sub>n</sub> (inclusive).
<code>binom(n, k)</code>	Binomial coefficient
<code>diric(x, n)</code>	Periodic sinc function, also called the Dirichlet function.
<code>euler(n)</code>	Euler numbers E <sub>0</sub> ..E <sub>n</sub> (inclusive).
<code>expn(n, x)</code>	Exponential integral E <sub>n</sub>
<code>expl(z)</code>	Exponential integral E <sub>1</sub> of complex argument <i>z</i>
<code>expi(x)</code>	Exponential integral E <sub>i</sub>
<code>factorial(n[, exact])</code>	The factorial of a number or array of numbers.
<code>factorial2(n[, exact])</code>	Double factorial.
<code>factorialk(n, k[, exact])</code>	Multifactorial of <i>n</i> of order <i>k</i> , $n(!\dots!)$ .
<code>shichi(x[, out])</code>	Hyperbolic sine and cosine integrals.
<code>sici(x[, out])</code>	Sine and cosine integrals.
<code>spence(z[, out])</code>	Spence's function, also known as the dilogarithm.
<code>zeta(x[, q, out])</code>	Riemann or Hurwitz zeta function.
<code>zetac(x)</code>	Riemann zeta function minus 1.

`scipy.special.agm(a, b) = <ufunc 'agm'>`  
 Compute the arithmetic-geometric mean of *a* and *b*.

Start with  $a_0 = a$  and  $b_0 = b$  and iteratively compute:

```
a_{n+1} = (a_n + b_n) / 2
b_{n+1} = sqrt(a_n * b_n)
```

`a_n` and `b_n` converge to the same limit as `n` increases; their common limit is `agm(a, b)`.

**Parameters** `a, b` : array\_like

Real values only. If the values are both negative, the result is negative. If one value is negative and the other is positive, `nan` is returned.

**Returns** float

The arithmetic-geometric mean of `a` and `b`.

### Examples

```
>>> from scipy.special import agm
>>> a, b = 24.0, 6.0
>>> agm(a, b)
13.458171481725614
```

Compare that result to the iteration:

```
>>> while a != b:
...     a, b = (a + b)/2, np.sqrt(a*b)
...     print("a = %19.16f b=%19.16f" % (a, b))
...
a = 15.000000000000000000 b=12.000000000000000000
a = 13.500000000000000000 b=13.4164078649987388
a = 13.4582039324993694 b=13.4581390309909850
a = 13.4581714817451772 b=13.4581714817060547
a = 13.4581714817256159 b=13.4581714817256159
```

When array-like arguments are given, broadcasting applies:

```
>>> a = np.array([[1.5], [3], [6]]) # a has shape (3, 1).
>>> b = np.array([6, 12, 24, 48]) # b has shape (4,).
>>> agm(a, b)
array([[ 3.36454287,  5.42363427,  9.05798751, 15.53650756],
       [ 4.37037309,  6.72908574, 10.84726853, 18.11597502],
       [ 6.          ,  8.74074619, 13.45817148, 21.69453707]])
```

`scipy.special.bernoulli` (`n`)

Bernoulli numbers  $B_0..B_n$  (inclusive).

### References

[R426]

`scipy.special.binom` (`n, k`) = <ufunc 'binom'>

Binomial coefficient

### See also:

**comb** The number of combinations of `N` things taken `k` at a time.

`scipy.special.diric` (`x, n`)

Periodic sinc function, also called the Dirichlet function.

The Dirichlet function is defined as:

$$\text{diric}(x) = \frac{\sin(x * n/2)}{(n * \sin(x / 2))},$$

where `n` is a positive integer.

**Parameters** `x` : array\_like

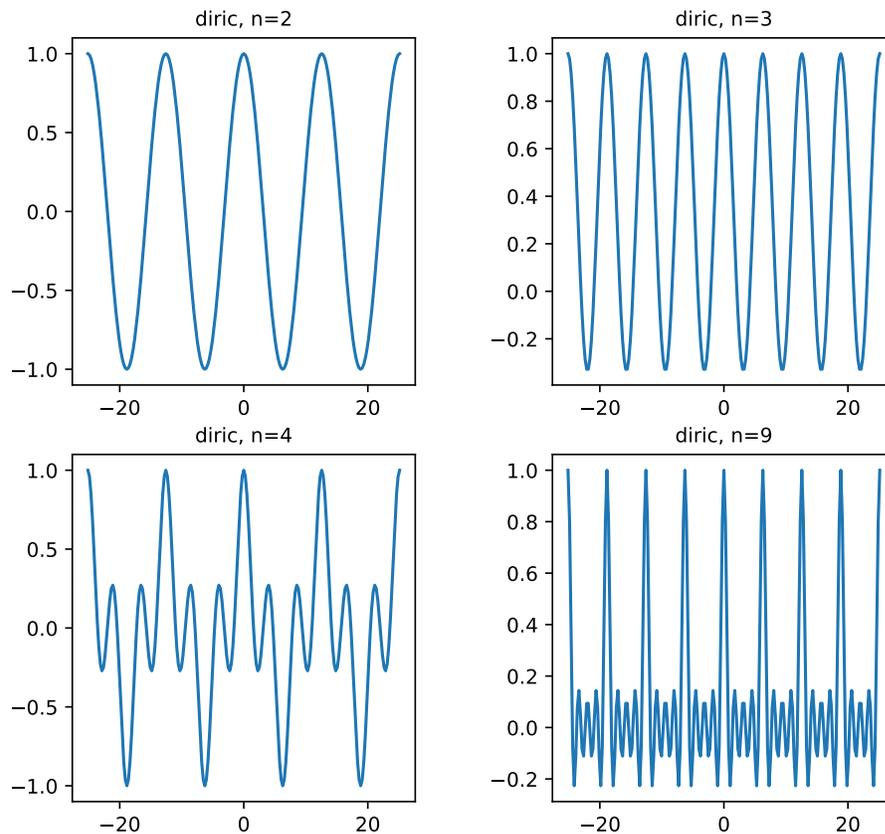

Input data

**Returns** `diric` : ndarray `n` : int  
 Integer defining the periodicity.

### Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-8*np.pi, 8*np.pi, num=201)
>>> plt.figure(figsize=(8, 8));
>>> for idx, n in enumerate([2, 3, 4, 9]):
...     plt.subplot(2, 2, idx+1)
...     plt.plot(x, special.diric(x, n))
...     plt.title('diric, n={}'.format(n))
>>> plt.show()
```

The following example demonstrates that `diric` gives the magnitudes (modulo the sign and scaling) of the

Fourier coefficients of a rectangular pulse.

Suppress output of values that are effectively 0:

```
>>> np.set_printoptions(suppress=True)
```

Create a signal  $x$  of length  $m$  with  $k$  ones:

```
>>> m = 8
>>> k = 3
>>> x = np.zeros(m)
>>> x[:k] = 1
```

Use the FFT to compute the Fourier transform of  $x$ , and inspect the magnitudes of the coefficients:

```
>>> np.abs(np.fft.fft(x))
array([ 3.          ,  2.41421356,  1.          ,  0.41421356,  1.          ,
        0.41421356,  1.          ,  2.41421356])
```

Now find the same values (up to sign) using *diric*. We multiply by  $k$  to account for the different scaling conventions of `numpy.fft.fft` and *diric*:

```
>>> theta = np.linspace(0, 2*np.pi, m, endpoint=False)
>>> k * special.diric(theta, k)
array([ 3.          ,  2.41421356,  1.          , -0.41421356, -1.          ,
       -0.41421356,  1.          ,  2.41421356])
```

`scipy.special.euler` ( $n$ )  
Euler numbers E<sub>0</sub>..E<sub>n</sub> (inclusive).

### References

[R463]

`scipy.special.expn` ( $n, x$ ) = <ufunc 'expn'>  
Exponential integral E<sub>n</sub>

Returns the exponential integral for integer  $n$  and non-negative  $x$  and  $n$ :

```
integral(exp(-x*t) / t**n, t=1..inf).
```

`scipy.special.exp1` ( $z$ ) = <ufunc 'exp1'>  
Exponential integral E<sub>1</sub> of complex argument  $z$

```
integral(exp(-z*t)/t, t=1..inf).
```

`scipy.special.expi` ( $x$ ) = <ufunc 'expi'>  
Exponential integral E<sub>i</sub>

Defined as:

```
integral(exp(t)/t, t=-inf..x)
```

See *expn* for a different exponential integral.

`scipy.special.factorial` ( $n$ , *exact=False*)  
The factorial of a number or array of numbers.

The factorial of non-negative integer  $n$  is the product of all positive integers less than or equal to  $n$ :

$$n! = n * (n - 1) * (n - 2) * \dots * 1$$

**Parameters**

- n** : int or array\_like of ints  
Input values. If  $n < 0$ , the return value is 0.
- exact** : bool, optional  
If True, calculate the answer exactly using long integer arithmetic. If False, result is approximated in floating point rapidly using the *gamma* function.

**Returns**

- nf** : float or int or ndarray  
Default is False.  
Factorial of  $n$ , as integer or float depending on *exact*.

### Notes

For arrays with `exact=True`, the factorial is computed only once, for the largest input, with each other result computed in the process. The output dtype is increased to `int64` or `object` if necessary.

With `exact=False` the factorial is approximated using the gamma function:

$$n! = \Gamma(n + 1)$$

### Examples

```
>>> from scipy.special import factorial
>>> arr = np.array([3, 4, 5])
>>> factorial(arr, exact=False)
array([ 6., 24., 120.])
>>> factorial(arr, exact=True)
array([ 6, 24, 120])
>>> factorial(5, exact=True)
120L
```

`scipy.special.factorial2` ( $n$ , *exact=False*)

Double factorial.

This is the factorial with every second value skipped. E.g.,  $7!! = 7 * 5 * 3 * 1$ . It can be approximated numerically as:

$$\begin{aligned} n!! &= \text{special.gamma}(n/2+1) * 2^{*(m+1)/2} / \text{sqrt}(\text{pi}) && n \text{ odd} \\ &= 2^{*(n/2)} * (n/2)! && n \text{ even} \end{aligned}$$

**Parameters**

- n** : int or array\_like  
Calculate  $n!!$ . Arrays are only supported with *exact* set to False. If  $n < 0$ , the return value is 0.
- exact** : bool, optional  
The result can be approximated rapidly using the gamma-formula above (default). If *exact* is set to True, calculate the answer exactly using integer arithmetic.

**Returns**

- nff** : float or int  
Double factorial of  $n$ , as an int or a float depending on *exact*.

### Examples

```
>>> from scipy.special import factorial2
>>> factorial2(7, exact=False)
array(105.00000000000001)
>>> factorial2(7, exact=True)
105L
```

`scipy.special.factorialk` ( $n, k, exact=True$ )  
 Multifactorial of  $n$  of order  $k$ ,  $n(!\dots!)$ .

This is the multifactorial of  $n$  skipping  $k$  values. For example,

$$\text{factorialk}(17, 4) = 17!!!! = 17 * 13 * 9 * 5 * 1$$

In particular, for any integer  $n$ , we have

$$\begin{aligned}\text{factorialk}(n, 1) &= \text{factorial}(n) \\ \text{factorialk}(n, 2) &= \text{factorial2}(n)\end{aligned}$$

**Parameters**

- n** : int  
Calculate multifactorial. If  $n < 0$ , the return value is 0.
- k** : int  
Order of multifactorial.
- exact** : bool, optional  
If exact is set to True, calculate the answer exactly using integer arithmetic.

**Returns**

- val** : int  
Multifactorial of  $n$ .

**Raises**

- NotImplementedError**  
Raises when exact is False

### Examples

```
>>> from scipy.special import factorialk
>>> factorialk(5, 1, exact=True)
120L
>>> factorialk(5, 3, exact=True)
10L
```

`scipy.special.shichi` ( $x, out=None$ ) = <ufunc 'shichi'>  
 Hyperbolic sine and cosine integrals.

The hyperbolic sine integral is

$$\int_0^x \frac{\sinh t}{t} dt$$

and the hyperbolic cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cosh t - 1}{t} dt$$

where  $\gamma$  is Euler's constant and  $\log$  is the principle branch of the logarithm.

**Parameters**

- x** : array\_like  
Real or complex points at which to compute the hyperbolic sine and cosine integrals.

**Returns**

- si** : ndarray  
Hyperbolic sine integral at  $x$
- ci** : ndarray  
Hyperbolic cosine integral at  $x$

### Notes

For real arguments with  $x < 0$ , `chi` is the real part of the hyperbolic cosine integral. For such points `chi(x)` and `chi(x + 0j)` differ by a factor of  $1j*\pi$ .

For real arguments the function is computed by calling Cephes' [R568] `shichi` routine. For complex arguments the algorithm is based on Mpmath's [R569] `shi` and `chi` routines.

**References**

[R568], [R569]

`scipy.special.sici(x, out=None) = <ufunc 'sici'>`

Sine and cosine integrals.

The sine integral is

$$\int_0^x \frac{\sin t}{t} dt$$

and the cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cos t - 1}{t} dt$$

where  $\gamma$  is Euler's constant and  $\log$  is the principle branch of the logarithm.

**Parameters** `x` : array\_like

**Returns** `si` : ndarray Real or complex points at which to compute the sine and cosine integrals.

Sine integral at `x`

`ci` : ndarray

Cosine integral at `x`

**Notes**

For real arguments with  $x < 0$ , `ci` is the real part of the cosine integral. For such points `ci(x)` and `ci(x + 0j)` differ by a factor of  $1j\pi$ .

For real arguments the function is computed by calling Cephes' [R570] `sici` routine. For complex arguments the algorithm is based on Mpmath's [R571] `si` and `ci` routines.

**References**

[R570], [R571]

`scipy.special.spence(z, out=None) = <ufunc 'spence'>`

Spence's function, also known as the dilogarithm.

It is defined to be

$$\int_0^z \frac{\log(t)}{1-t} dt$$

for complex  $z$ , where the contour of integration is taken to avoid the branch cut of the logarithm. Spence's function is analytic everywhere except the negative real axis where it has a branch cut.

**Parameters** `z` : array\_like

**Returns** `s` : ndarray Points at which to evaluate Spence's function

Computed values of Spence's function

**Notes**

There is a different convention which defines Spence's function by the integral

$$-\int_0^z \frac{\log(1-t)}{t} dt;$$

this is our `spence(1 - z)`.

`scipy.special.zeta` ( $x, q=None, out=None$ )

Riemann or Hurwitz zeta function.

**Parameters**

- x** : array\_like of float  
Input data, must be real
- q** : array\_like of float, optional  
Input data, must be real. Defaults to Riemann zeta.
- out** : ndarray, optional  
Output array for the computed values.

**See also:**

`zetac`

**Notes**

The two-argument version is the Hurwitz zeta function:

$$\zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k+q)^x},$$

Riemann zeta function corresponds to  $q = 1$ .

`scipy.special.zetac` ( $x$ ) = <ufunc 'zetac'>

Riemann zeta function minus 1.

This function is defined as

$$\zeta(x) = \sum_{k=2}^{\infty} 1/k^x,$$

where  $x > 1$ .

**See also:**

`zeta`

## Convenience Functions

<code>cbrt(x)</code>	Element-wise cube root of $x$ .
<code>exp10(x)</code>	Compute $10^{**x}$ element-wise.
<code>exp2(x)</code>	Compute $2^{**x}$ element-wise.
<code>radian(d, m, s)</code>	Convert from degrees to radians
<code>cosdg(x)</code>	Cosine of the angle $x$ given in degrees.
<code>sindg(x)</code>	Sine of angle given in degrees
<code>tandg(x)</code>	Tangent of angle $x$ given in degrees.
<code>cotdg(x)</code>	Cotangent of the angle $x$ given in degrees.
<code>log1p(x)</code>	Calculates $\log(1+x)$ for use when $x$ is near zero
<code>expm1(x)</code>	Compute $\exp(x) - 1$ .
<code>cosm1(x)</code>	$\cos(x) - 1$ for use when $x$ is near zero.
<code>round(x)</code>	Round to nearest integer
<code>xlogy(x, y)</code>	Compute $x * \log(y)$ so that the result is 0 if $x = 0$ .
<code>xlog1py(x, y)</code>	Compute $x * \log1p(y)$ so that the result is 0 if $x = 0$ .
<code>logsumexp(a[, axis, b, keepdims, return_sign])</code>	Compute the log of the sum of exponentials of input elements.
<code>exprel(x)</code>	Relative error exponential, $(\exp(x) - 1) / x$ .
<code>sinc(x)</code>	Return the sinc function.

`scipy.special.cbrt(x) = <ufunc 'cbrt'>`

Element-wise cube root of  $x$ .

**Parameters** `x`: array\_like  
**Returns** float  
 $x$  must contain real numbers.  
The cube root of each value in  $x$ .

**Examples**

```
>>> from scipy.special import cbrt
```

```
>>> cbrt(8)
2.0
>>> cbrt([-8, -3, 0.125, 1.331])
array([-2.          , -1.44224957,  0.5          ,  1.1          ])
```

`scipy.special.exp10(x) = <ufunc 'exp10'>`

Compute  $10^{**x}$  element-wise.

**Parameters** `x`: array\_like  
**Returns** float  
 $x$  must contain real numbers.  
 $10^{**x}$ , computed element-wise.

**Examples**

```
>>> from scipy.special import exp10
```

```
>>> exp10(3)
1000.0
>>> x = np.array([[ -1, -0.5,  0], [ 0.5,  1,  1.5]])
>>> exp10(x)
array([[ 0.1          ,  0.31622777,  1.          ],
       [ 3.16227766,  10.          ,  31.6227766 ]])
```

`scipy.special.exp2(x) = <ufunc 'exp2'>`

Compute  $2^{**x}$  element-wise.

**Parameters** `x`: array\_like  
**Returns** float  
 $x$  must contain real numbers.  
 $2^{**x}$ , computed element-wise.

**Examples**

```
>>> from scipy.special import exp2
```

```
>>> exp2(3)
8.0
>>> x = np.array([[ -1, -0.5,  0], [ 0.5,  1,  1.5]])
>>> exp2(x)
array([[ 0.5          ,  0.70710678,  1.          ],
       [ 1.41421356,  2.          ,  2.82842712]])
```

`scipy.special.radians(d, m, s) = <ufunc 'radians'>`

Convert from degrees to radians

Returns the angle given in (d)egrees, (m)inutes, and (s)econds in radians.

`scipy.special.cosdg(x) = <ufunc 'cosdg'>`  
Cosine of the angle  $x$  given in degrees.

`scipy.special.sindg(x) = <ufunc 'sindg'>`  
Sine of angle given in degrees

`scipy.special.tandg(x) = <ufunc 'tandg'>`  
Tangent of angle  $x$  given in degrees.

`scipy.special.cotdg(x) = <ufunc 'cotdg'>`  
Cotangent of the angle  $x$  given in degrees.

`scipy.special.log1p(x) = <ufunc 'log1p'>`  
Calculates  $\log(1+x)$  for use when  $x$  is near zero

`scipy.special.expm1(x) = <ufunc 'expm1'>`  
Compute  $\exp(x) - 1$ .

When  $x$  is near zero,  $\exp(x)$  is near 1, so the numerical calculation of  $\exp(x) - 1$  can suffer from catastrophic loss of precision. `expm1(x)` is implemented to avoid the loss of precision that occurs when  $x$  is near zero.

**Parameters** `x`: array\_like  
`x` must contain real numbers.

**Returns** float  
 $\exp(x) - 1$  computed element-wise.

### Examples

```
>>> from scipy.special import expm1
```

```
>>> expm1(1.0)
1.7182818284590451
>>> expm1([-0.2, -0.1, 0, 0.1, 0.2])
array([-0.18126925, -0.09516258, 0.          , 0.10517092, 0.22140276])
```

The exact value of  $\exp(7.5e-13) - 1$  is:

```
7.5000000000028125000000007031250000001318...*10**-13.
```

Here is what `expm1(7.5e-13)` gives:

```
>>> expm1(7.5e-13)
7.5000000000028135e-13
```

Compare that to  $\exp(7.5e-13) - 1$ , where the subtraction results in a “catastrophic” loss of precision:

```
>>> np.exp(7.5e-13) - 1
7.5006667543675576e-13
```

`scipy.special.cosm1(x) = <ufunc 'cosm1'>`  
 $\cos(x) - 1$  for use when  $x$  is near zero.

`scipy.special.round(x) = <ufunc 'round'>`  
Round to nearest integer

Returns the nearest integer to  $x$  as a double precision floating point result. If  $x$  ends in 0.5 exactly, the nearest even integer is chosen.

`scipy.special.xlogy(x, y) = <ufunc 'xlogy'>`  
Compute  $x \cdot \log(y)$  so that the result is 0 if  $x = 0$ .

**Parameters** **x** : array\_like  
Multiplier  
**y** : array\_like  
**Returns** **z** : array\_like  
Argument  
Computed  $x \cdot \log(y)$

**Notes**

New in version 0.13.0.

`scipy.special.xlog1py(x, y) = <ufunc 'xlog1py'>`  
Compute  $x \cdot \log_1 p(y)$  so that the result is 0 if  $x = 0$ .

**Parameters** **x** : array\_like  
Multiplier  
**y** : array\_like  
**Returns** **z** : array\_like  
Argument  
Computed  $x \cdot \log_1 p(y)$

**Notes**

New in version 0.13.0.

`scipy.special.logsumexp(a, axis=None, b=None, keepdims=False, return_sign=False)`  
Compute the log of the sum of exponentials of input elements.

**Parameters** **a** : array\_like  
Input array.  
**axis** : None or int or tuple of ints, optional  
Axis or axes over which the sum is taken. By default *axis* is None, and all elements are summed.  
New in version 0.11.0.  
**keepdims** : bool, optional  
If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array.  
New in version 0.15.0.  
**b** : array-like, optional  
Scaling factor for  $\exp(a)$  must be of the same shape as *a* or broadcastable to *a*. These values may be negative in order to implement subtraction.  
New in version 0.12.0.  
**return\_sign** : bool, optional  
If this is set to True, the result will be a pair containing sign information; if False, results that are negative will be returned as NaN. Default is False (no sign information).  
New in version 0.16.0.

**Returns**

---

**res** : ndarray  
The result,  $\text{np.log}(\text{np.sum}(\text{np.exp}(a)))$  calculated in a numerically more stable way. If *b* is given then  $\text{np.log}(\text{np.sum}(b \cdot \text{np.exp}(a)))$  is returned.

**sgn** : ndarray  
If *return\_sign* is True, this will be an array of floating-point numbers matching *res* and +1, 0, or -1 depending on the sign of the result. If False, only one result is returned.

**See also:**

`numpy.logaddexp`, `numpy.logaddexp2`

**Notes**

Numpy has a `logaddexp` function which is very similar to `logsumexp`, but only handles two arguments. `logaddexp.reduce` is similar to this function, but may be less stable.

**Examples**

```
>>> from scipy.special import logsumexp
>>> a = np.arange(10)
>>> np.log(np.sum(np.exp(a)))
9.4586297444267107
>>> logsumexp(a)
9.4586297444267107
```

**With weights**

```
>>> a = np.arange(10)
>>> b = np.arange(10, 0, -1)
>>> logsumexp(a, b=b)
9.9170178533034665
>>> np.log(np.sum(b*np.exp(a)))
9.9170178533034647
```

**Returning a sign flag**

```
>>> logsumexp([1,2], b=[1,-1], return_sign=True)
(1.5413248546129181, -1.0)
```

Notice that `logsumexp` does not directly support masked arrays. To use it on a masked array, convert the mask into zero weights:

```
>>> a = np.ma.array([np.log(2), 2, np.log(3)],
...                 mask=[False, True, False])
>>> b = (~a.mask).astype(int)
>>> logsumexp(a.data, b=b), np.log(5)
1.6094379124341005, 1.6094379124341005
```

`scipy.special.exprel(x) = <ufunc 'exprel'>`

Relative error exponential,  $(\exp(x) - 1)/x$ .

When  $x$  is near zero,  $\exp(x)$  is near 1, so the numerical calculation of  $\exp(x) - 1$  can suffer from catastrophic loss of precision. `exprel(x)` is implemented to avoid the loss of precision that occurs when  $x$  is near zero.

**Parameters** `x`: ndarray

**Returns** float

Input array.  $x$  must contain real numbers.

$(\exp(x) - 1)/x$ , computed element-wise.

**See also:**

`expm1`

**Notes**

New in version 0.17.0.

*Examples*

```
>>> from scipy.special import exprel
```

```
>>> exprel(0.01)
1.0050167084168056
>>> exprel([-0.25, -0.1, 0, 0.1, 0.25])
array([ 0.88479687,  0.95162582,  1.          ,  1.05170918,  1.13610167])
```

Compare `exprel(5e-9)` to the naive calculation. The exact value is `1.00000000250000000416...`

```
>>> exprel(5e-9)
1.0000000025
```

```
>>> (np.exp(5e-9) - 1)/5e-9
0.99999999392252903
```

`scipy.special.sinc(x)`

Return the sinc function.

The sinc function is  $\sin(\pi x)/(\pi x)$ .

<b>Parameters</b>	<b>x</b> : ndarray	Array (possibly multi-dimensional) of values for which to calculate <code>sinc(x)</code> .
<b>Returns</b>	<b>out</b> : ndarray	<code>sinc(x)</code> , which has the same shape as the input.

*Notes*

`sinc(0)` is the limit value 1.

The name `sinc` is short for “sine cardinal” or “sinus cardinalis”.

The sinc function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the sinc function.

*References*

[R572], [R573]

*Examples*

```
>>> x = np.linspace(-4, 4, 41)
>>> np.sinc(x)
array([ -3.89804309e-17, -4.92362781e-02, -8.40918587e-02,
        -8.90384387e-02, -5.84680802e-02,  3.89804309e-17,
         6.68206631e-02,  1.16434881e-01,  1.26137788e-01,
         8.50444803e-02, -3.89804309e-17, -1.03943254e-01,
        -1.89206682e-01, -2.16236208e-01, -1.55914881e-01,
         3.89804309e-17,  2.33872321e-01,  5.04551152e-01,
         7.56826729e-01,  9.35489284e-01,  1.00000000e+00,
         9.35489284e-01,  7.56826729e-01,  5.04551152e-01,
         2.33872321e-01,  3.89804309e-17, -1.55914881e-01,
        -2.16236208e-01, -1.89206682e-01, -1.03943254e-01,
        -3.89804309e-17,  8.50444803e-02,  1.26137788e-01,
         1.16434881e-01,  6.68206631e-02,  3.89804309e-17,])
```

```
-5.84680802e-02, -8.90384387e-02, -8.40918587e-02,
-4.92362781e-02, -3.89804309e-17])
```

```
>>> plt.plot(x, np.sinc(x))
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.title("Sinc Function")
<matplotlib.text.Text object at 0x...>
>>> plt.ylabel("Amplitude")
<matplotlib.text.Text object at 0x...>
>>> plt.xlabel("X")
<matplotlib.text.Text object at 0x...>
>>> plt.show()
```

It works in 2-D as well:

```
>>> x = np.linspace(-4, 4, 401)
>>> xx = np.outer(x, x)
>>> plt.imshow(np.sinc(xx))
<matplotlib.image.AxesImage object at 0x...>
```

## 5.27 Statistical functions (`scipy.stats`)

This module contains a large number of probability distributions as well as a growing library of statistical functions.

Each univariate distribution is an instance of a subclass of `rv_continuous` (`rv_discrete` for discrete distributions):

<code>rv_continuous([momtype, a, b, xtol, ...])</code>	A generic continuous random variable class meant for subclassing.
<code>rv_discrete([a, b, name, badvalue, ...])</code>	A generic discrete random variable class meant for subclassing.
<code>rv_histogram(histogram, *args, **kwargs)</code>	Generates a distribution given by a histogram.

```
class scipy.stats.rv_continuous (momtype=1, a=None, b=None, xtol=1e-14, badvalue=None,
name=None, longname=None, shapes=None, extradoc=None,
seed=None)
```

A generic continuous random variable class meant for subclassing.

`rv_continuous` is a base class to construct specific distribution classes and instances for continuous random variables. It cannot be used directly as a distribution.

**Parameters**

- momtype** : int, optional  
The type of generic moment calculation to use: 0 for pdf, 1 (default) for ppf.
- a** : float, optional  
Lower bound of the support of the distribution, default is minus infinity.
- b** : float, optional  
Upper bound of the support of the distribution, default is plus infinity.
- xtol** : float, optional  
The tolerance for fixed point calculation for generic ppf.
- badvalue** : float, optional  
The value in a result arrays that indicates a value that for which some argument restriction is violated, default is `np.nan`.

- name** : str, optional  
The name of the instance. This string is used to construct the default example for distributions.
- longname** : str, optional  
This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: *longname* exists for backwards compatibility, do not use for new subclasses.
- shapes** : str, optional  
The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signature of the private methods, `_pdf` and `_cdf` of the instance.
- extradoc** : str, optional, deprecated  
This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: *extradoc* exists for backwards compatibility, do not use for new subclasses.
- seed** : None or int or `numpy.random.RandomState` instance, optional  
This parameter defines the `RandomState` object to use for drawing random variates. If None (or `np.random`), the global `np.random` state is used. If integer, it is used to seed the local `RandomState` instance. Default is None.

### Notes

Public methods of an instance of a distribution class (e.g., `pdf`, `cdf`) check their arguments and pass valid arguments to private, computational methods (`_pdf`, `_cdf`). For `pdf(x)`, `x` is valid if it is within the support of a distribution, `self.a <= x <= self.b`. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.)

### Subclassing

New random variables can be defined by subclassing the `rv_continuous` class and re-defining at least the `_pdf` or the `_cdf` method (normalized to location 0 and scale 1).

If positive argument checking is not correct for your RV then you will also need to re-define the `_argcheck` method.

Correct, but potentially slow defaults exist for the remaining methods but for speed and/or accuracy you can over-ride:

```
_logpdf, _cdf, _logcdf, _ppf, _rvs, _isf, _sf, _logsf
```

Rarely would you override `_isf`, `_sf` or `_logsf`, but you could.

### Methods that can be overwritten by subclasses

```
_rvs
_pdf
_cdf
_sf
_ppf
_isf
_stats
_munp
_entropy
_argcheck
```

There are additional (internal and private) generic methods that can be useful for cross-checking and for debugging, but might work in all cases when directly called.

A note on `shapes`: subclasses need not specify them explicitly. In this case, `shapes` will be automatically deduced from the signatures of the overridden methods (`pdf`, `cdf` etc). If, for some reason, you prefer to avoid relying on introspection, you can specify `shapes` explicitly as an argument to the instance constructor.

### Frozen Distributions

Normally, you must provide shape parameters (and, optionally, location and scale parameters to each call of a method of a distribution.

Alternatively, the object may be called (as a function) to fix the shape, location, and scale parameters returning a “frozen” continuous RV object:

```
rv = generic(<shape(s)>, loc=0, scale=1)
```

frozen RV object with the same methods but holding the given shape, location, and scale fixed

### Statistics

Statistics are computed using numerical integration by default. For speed you can redefine this using `_stats`:

- take shape parameters and return `mu`, `mu2`, `g1`, `g2`
- If you can’t compute one of these, return it as `None`
- Can also be defined with a keyword argument `moments`, which is a string composed of “m”, “v”, “s”, and/or “k”. Only the components appearing in string should be computed and returned in the order “m”, “v”, “s”, or “k” with missing values returned as `None`.

Alternatively, you can override `_munp`, which takes `n` and shape parameters and returns the `n`-th non-central moment of the distribution.

### Examples

To create a new Gaussian distribution, we would do the following:

```
>>> from scipy.stats import rv_continuous
>>> class gaussian_gen(rv_continuous):
...     "Gaussian distribution"
...     def _pdf(self, x):
...         return np.exp(-x**2 / 2.) / np.sqrt(2.0 * np.pi)
>>> gaussian = gaussian_gen(name='gaussian')
```

`scipy.stats` distributions are *instances*, so here we subclass `rv_continuous` and create an instance. With this, we now have a fully functional distribution with all relevant methods automatically generated by the framework.

Note that above we defined a standard normal distribution, with zero mean and unit variance. Shifting and scaling of the distribution can be done by using `loc` and `scale` parameters: `gaussian.pdf(x, loc, scale)` essentially computes  $y = (x - \text{loc}) / \text{scale}$  and `gaussian._pdf(y) / scale`.

### Attributes

<code>random_state</code>	Get or set the <code>RandomState</code> object for generating random variates.
---------------------------	--

### `rv_continuous.random_state`

Get or set the `RandomState` object for generating random variates.

This can be either `None` or an existing `RandomState` object.

If `None` (or `np.random`), use the `RandomState` singleton used by `np.random`. If already a `RandomState` instance, use it. If an `int`, use a new `RandomState` instance seeded with `seed`.

### Methods

<code>rvs(*args, **kwargs)</code>	Random variates of given type.
<code>pdf(x, *args, **kwargs)</code>	Probability density function at x of the given RV.
<code>logpdf(x, *args, **kwargs)</code>	Log of the probability density function at x of the given RV.
<code>cdf(x, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>logcdf(x, *args, **kwargs)</code>	Log of the cumulative distribution function at x of the given RV.
<code>sf(x, *args, **kwargs)</code>	Survival function (1 - <i>cdf</i> ) at x of the given RV.
<code>logsf(x, *args, **kwargs)</code>	Log of the survival function of the given RV.
<code>ppf(q, *args, **kwargs)</code>	Percent point function (inverse of <i>cdf</i> ) at q of the given RV.
<code>isf(q, *args, **kwargs)</code>	Inverse survival function (inverse of <i>sf</i> ) at q of the given RV.
<code>moment(n, *args, **kwargs)</code>	n-th order non-central moment of distribution.
<code>stats(*args, **kwargs)</code>	Some statistics of the given RV.
<code>entropy(*args, **kwargs)</code>	Differential entropy of the RV.
<code>expect([func, args, loc, scale, lb, ub, ...])</code>	Calculate expected value of a function with respect to the distribution.
<code>median(*args, **kwargs)</code>	Median of the distribution.
<code>mean(*args, **kwargs)</code>	Mean of the distribution.
<code>std(*args, **kwargs)</code>	Standard deviation of the distribution.
<code>var(*args, **kwargs)</code>	Variance of the distribution.
<code>interval(alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>__call__(*args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>fit(data, *args, **kwargs)</code>	Return MLEs for shape (if applicable), location, and scale parameters from data.
<code>fit_loc_scale(data, *args)</code>	Estimate loc and scale parameters from data using 1st and 2nd moments.
<code>nllf(theta, x)</code>	Return negative loglikelihood function.

`rv_continuous.rvs(*args, **kwargs)`

Random variates of given type.

**Parameters** `arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information).

`loc` : array\_like, optional

Location parameter (default=0).

`scale` : array\_like, optional

Scale parameter (default=1).

`size` : int or tuple of ints, optional

Defining number of random variates (default is 1).

`random_state` : None or int or `np.random.RandomState` instance, optional

If int or `RandomState`, use it for drawing the random variates. If None, rely on `self.random_state`. Default is None.

**Returns** `rvs` : ndarray or scalar

Random variates of given *size*.

`rv_continuous.pdf(x, *args, **kwargs)`

Probability density function at x of the given RV.

**Parameters** `x` : array\_like

quantiles

`arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **pdf** : ndarray  
Probability density function evaluated at x

`rv_continuous.logpdf(x, *args, **kwargs)`  
Log of the probability density function at x of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters** **x** : array\_like  
quantiles

**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **logpdf** : array\_like  
Log of the probability density function evaluated at x

`rv_continuous.cdf(x, *args, **kwargs)`  
Cumulative distribution function of the given RV.

**Parameters** **x** : array\_like  
quantiles

**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **cdf** : ndarray  
Cumulative distribution function evaluated at x

`rv_continuous.logcdf(x, *args, **kwargs)`  
Log of the cumulative distribution function at x of the given RV.

**Parameters** **x** : array\_like  
quantiles

**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **logcdf** : array\_like  
Log of the cumulative distribution function evaluated at x

`rv_continuous.sf(x, *args, **kwargs)`  
Survival function (1 - *cdf*) at x of the given RV.

**Parameters** **x** : array\_like

`quantiles`  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **sf** : array\_like  
 Survival function evaluated at  $x$

`rv_continuous.logsf(x, *args, **kws)`  
 Log of the survival function of the given RV.  
 Returns the log of the “survival function,” defined as  $(1 - cdf)$ , evaluated at  $x$ .

**Parameters** **x** : array\_like  
`quantiles`  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **logsf** : ndarray  
 Log of the survival function evaluated at  $x$ .

`rv_continuous.ppf(q, *args, **kws)`  
 Percent point function (inverse of  $cdf$ ) at  $q$  of the given RV.

**Parameters** **q** : array\_like  
 lower tail probability  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **x** : array\_like  
 quantile corresponding to the lower tail probability  $q$ .

`rv_continuous.isf(q, *args, **kws)`  
 Inverse survival function (inverse of  $sf$ ) at  $q$  of the given RV.

**Parameters** **q** : array\_like  
 upper tail probability  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **x** : ndarray or scalar  
 Quantile corresponding to the upper tail probability  $q$ .

`rv_continuous.moment(n, *args, **kws)`  
 $n$ -th order non-central moment of distribution.

**Parameters**

- n** : int,  $n \geq 1$   
Order of moment.
- arg1, arg2, arg3,...** : float  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** : array\_like, optional  
location parameter (default=0)
- scale** : array\_like, optional  
scale parameter (default=1)

`rv_continuous.stats` (\*args, \*\*kws)  
Some statistics of the given RV.

**Parameters**

- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc** : array\_like, optional  
location parameter (default=0)
- scale** : array\_like, optional (continuous RVs only)  
scale parameter (default=1)
- moments** : str, optional  
composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns**

- stats** : sequence  
of requested moments.

`rv_continuous.entropy` (\*args, \*\*kws)  
Differential entropy of the RV.

**Parameters**

- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** : array\_like, optional  
Location parameter (default=0).
- scale** : array\_like, optional (continuous distributions only).  
Scale parameter (default=1).

### Notes

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

`rv_continuous.expect` (func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, \*\*kws)

Calculate expected value of a function with respect to the distribution.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[x] = \int_{lb}^{ub} f(x) * dist.pdf(x)$$

**Parameters**

- func** : callable, optional

Function for which integral is calculated. Takes only one argument.  
The default is the identity mapping  $f(x) = x$ .

**args** : tuple, optional

Shape parameters of the distribution.

**loc** : float, optional

Location parameter (default=0).

**scale** : float, optional

Scale parameter (default=1).

**lb, ub** : scalar, optional

Lower and upper bound for integration. Default is set to the support of the distribution.

**conditional** : bool, optional

If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

**Returns** **Additional keyword arguments are passed to the integration routine.**

**expect** : float

The calculated expected value.

**Notes**

The integration behavior of this function is inherited from *integrate.quad*.

`rv_continuous.median(*args, **kws)`

Median of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

Location parameter, Default is 0.

**scale** : array\_like, optional

Scale parameter, Default is 1.

**Returns** **median** : float

The median of the distribution.

**See also:**

***stats.distributions.rv\_discrete.ppf***

Inverse of the CDF

`rv_continuous.mean(*args, **kws)`

Mean of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional

scale parameter (default=1)

**Returns** **mean** : float

the mean of the distribution

`rv_continuous.std(*args, **kws)`

Standard deviation of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)  
**scale** : array\_like, optional  
scale parameter (default=1)  
**Returns** **std** : float  
standard deviation of the distribution

`rv_continuous.var(*args, **kws)`  
Variance of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
location parameter (default=0)  
**scale** : array\_like, optional  
scale parameter (default=1)  
**Returns** **var** : float  
the variance of the distribution

`rv_continuous.interval(alpha, *args, **kws)`  
Confidence interval with equal areas around the median.

**Parameters** **alpha** : array\_like of float  
Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].  
**arg1, arg2, ...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
location parameter, Default is 0.  
**scale** : array\_like, optional  
scale parameter, Default is 1.  
**Returns** **a, b** : ndarray of float  
end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

`rv_continuous.__call__(*args, **kws)`  
Freeze the distribution for the given arguments.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.  
**Returns** **rv\_frozen** : rv\_frozen instance  
The frozen distribution.

`rv_continuous.fit(data, *args, **kws)`  
Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

**Parameters** **data** : array\_like  
Data to use in calculating the MLEs.  
**args** : floats, optional

Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

**kwds** : floats, optional

Starting values for the location and scale parameters; no default. Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
- `floc` : hold location parameter fixed to specified value.
- `fscale` : hold scale parameter fixed to specified value.
- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

**Returns**

**mle\_tuple** : tuple of floats

MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

### Notes

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

### Examples

Generate some data to fit: draw random variates from the *beta* distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```

>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)

```

`rv_continuous.fit_loc_scale` (*data*, \**args*)

Estimate loc and scale parameters from data using 1st and 2nd moments.

**Parameters**

- data** : array\_like  
Data to fit.
- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**Returns**

- Lhat** : float  
Estimated location parameter for the data.
- Shat** : float  
Estimated scale parameter for the data.

`rv_continuous.nllf` (*theta*, *x*)

Return negative loglikelihood function.

#### Notes

This is  $-\text{sum}(\log \text{pdf}(x, \text{theta}), \text{axis}=0)$  where *theta* are the parameters (including loc and scale).

**class** `scipy.stats.rv_discrete` (*a=0*, *b=inf*, *name=None*, *badvalue=None*, *moment\_tol=1e-08*, *values=None*, *inc=1*, *longname=None*, *shaper=None*, *extradoc=None*, *seed=None*)

A generic discrete random variable class meant for subclassing.

*rv\_discrete* is a base class to construct specific distribution classes and instances for discrete random variables. It can also be used to construct an arbitrary distribution defined by a list of support points and corresponding probabilities.

**Parameters**

- a** : float, optional  
Lower bound of the support of the distribution, default: 0
- b** : float, optional  
Upper bound of the support of the distribution, default: plus infinity
- moment\_tol** : float, optional  
The tolerance for the generic calculation of moments.
- values** : tuple of two array\_like, optional  
(*xk*, *pk*) where *xk* are integers with non-zero probabilities *pk* with  $\text{sum}(pk) = 1$ .
- inc** : integer, optional  
Increment for the support of the distribution. Default is 1. (other values have not been tested)
- badvalue** : float, optional  
The value in a result arrays that indicates a value that for which some argument restriction is violated, default is `np.nan`.
- name** : str, optional  
The name of the instance. This string is used to construct the default example for distributions.
- longname** : str, optional  
This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: *longname* exists for backwards compatibility, do not use for new subclasses.

**shapes** : str, optional

The shape of the distribution. For example “m, n” for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signatures of the private methods, `_pmf` and `_cdf` of the instance.

**extradoc** : str, optional

This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: *extradoc* exists for backwards compatibility, do not use for new subclasses.

**seed** : None or int or `numpy.random.RandomState` instance, optional

This parameter defines the `RandomState` object to use for drawing random variates. If None, the global `np.random` state is used. If integer, it is used to seed the local `RandomState` instance. Default is None.

### Notes

This class is similar to `rv_continuous`. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.) The main differences are:

- the support of the distribution is a set of integers
- instead of the probability density function, `pdf` (and the corresponding private `_pdf`), this class defines the *probability mass function*, `pmf` (and the corresponding private `_pmf`.)
- scale parameter is not defined.

To create a new discrete distribution, we would do the following:

```
>>> from scipy.stats import rv_discrete
>>> class poisson_gen(rv_discrete):
...     "Poisson distribution"
...     def _pmf(self, k, mu):
...         return exp(-mu) * mu**k / factorial(k)
```

and create an instance:

```
>>> poisson = poisson_gen(name="poisson")
```

Note that above we defined the Poisson distribution in the standard form. Shifting the distribution can be done by providing the `loc` parameter to the methods of the instance. For example, `poisson.pmf(x, mu, loc)` delegates the work to `poisson._pmf(x-loc, mu)`.

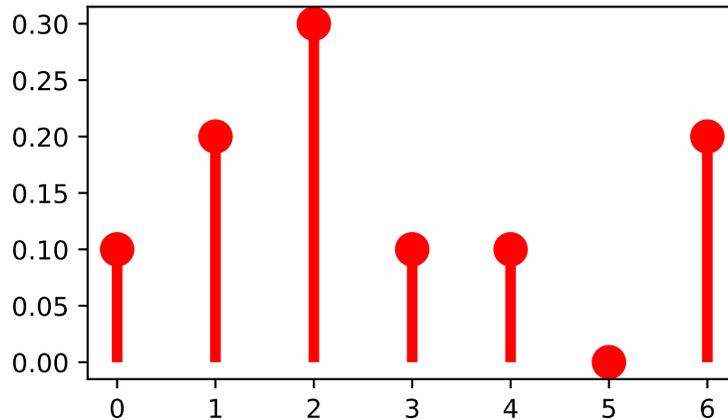

### Discrete distributions from a list of probabilities

Alternatively, you can construct an arbitrary discrete rv defined on a finite set of values  $x_k$  with  $\text{Prob}\{X=x_k\} = p_k$  by using the `values` keyword argument to the `rv_discrete` constructor.

### Examples

Custom made discrete distribution:

```
>>> from scipy import stats
>>> xk = np.arange(7)
>>> pk = (0.1, 0.2, 0.3, 0.1, 0.1, 0.0, 0.2)
>>> custm = stats.rv_discrete(name='custm', values=(xk, pk))
>>>
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
>>> ax.plot(xk, custm.pmf(xk), 'ro', ms=12, mec='r')
>>> ax.vlines(xk, 0, custm.pmf(xk), colors='r', lw=4)
>>> plt.show()
```

Random number generation:

```
>>> R = custom.rvs(size=100)
```

### Attributes

<code>random_state</code>	Get or set the RandomState object for generating random variates.
---------------------------	---

### `rv_discrete.random_state`

Get or set the RandomState object for generating random variates.

This can be either None or an existing RandomState object.

If None (or `np.random`), use the RandomState singleton used by `np.random`. If already a RandomState instance, use it. If an int, use a new RandomState instance seeded with `seed`.

### Methods

<code>rvs(*args, **kwargs)</code>	Random variates of given type.
<code>pmf(k, *args, **kwargs)</code>	Probability mass function at $k$ of the given RV.
<code>logpmf(k, *args, **kwargs)</code>	Log of the probability mass function at $k$ of the given RV.
<code>cdf(k, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>logcdf(k, *args, **kwargs)</code>	Log of the cumulative distribution function at $k$ of the given RV.
<code>sf(k, *args, **kwargs)</code>	Survival function ( $1 - cdf$ ) at $k$ of the given RV.
<code>logsf(k, *args, **kwargs)</code>	Log of the survival function of the given RV.
<code>ppf(q, *args, **kwargs)</code>	Percent point function (inverse of $cdf$ ) at $q$ of the given RV.
<code>isf(q, *args, **kwargs)</code>	Inverse survival function (inverse of $sf$ ) at $q$ of the given RV.
<code>moment(n, *args, **kwargs)</code>	$n$ -th order non-central moment of distribution.
<code>stats(*args, **kwargs)</code>	Some statistics of the given RV.

Continued on next page

Table 5.284 – continued from previous page

<code>entropy(*args, **kwargs)</code>	Differential entropy of the RV.
<code>expect([func, args, loc, lb, ub, ...])</code>	Calculate expected value of a function with respect to the distribution for discrete distribution.
<code>median(*args, **kwargs)</code>	Median of the distribution.
<code>mean(*args, **kwargs)</code>	Mean of the distribution.
<code>std(*args, **kwargs)</code>	Standard deviation of the distribution.
<code>var(*args, **kwargs)</code>	Variance of the distribution.
<code>interval(alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>__call__(*args, **kwargs)</code>	Freeze the distribution for the given arguments.

`rv_discrete.rvs(*args, **kwargs)`

Random variates of given type.

**Parameters** `arg1, arg2, arg3,...` : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information).

`loc` : array\_like, optional  
 Location parameter (default=0).

`size` : int or tuple of ints, optional  
 Defining number of random variates (Default is 1). Note that *size* has to be given as keyword, not as positional argument.

`random_state` : None or int or `np.random.RandomState` instance, optional  
 If int or `RandomState`, use it for drawing the random variates. If None, rely on `self.random_state`. Default is None.

**Returns** `rvs` : ndarray or scalar  
 Random variates of given *size*.

`rv_discrete.pmf(k, *args, **kwargs)`

Probability mass function at k of the given RV.

**Parameters** `k` : array\_like  
 Quantiles.

`arg1, arg2, arg3,...` : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)

`loc` : array\_like, optional  
 Location parameter (default=0).

**Returns** `pmf` : array\_like  
 Probability mass function evaluated at k

`rv_discrete.logpmf(k, *args, **kwargs)`

Log of the probability mass function at k of the given RV.

**Parameters** `k` : array\_like  
 Quantiles.

`arg1, arg2, arg3,...` : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information).

`loc` : array\_like, optional  
 Location parameter. Default is 0.

**Returns** `logpmf` : array\_like  
 Log of the probability mass function evaluated at k.

`rv_discrete.cdf(k, *args, **kwargs)`

Cumulative distribution function of the given RV.

**Parameters** `k` : array\_like, int

Quantiles.  
**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
Location parameter (default=0).  
**Returns** **cdf** : ndarray  
Cumulative distribution function evaluated at  $k$ .

`rv_discrete.logcdf(k, *args, **kws)`  
Log of the cumulative distribution function at  $k$  of the given RV.

**Parameters** **k** : array\_like, int  
Quantiles.  
**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
Location parameter (default=0).  
**Returns** **logcdf** : array\_like  
Log of the cumulative distribution function evaluated at  $k$ .

`rv_discrete.sf(k, *args, **kws)`  
Survival function ( $1 - cdf$ ) at  $k$  of the given RV.

**Parameters** **k** : array\_like  
Quantiles.  
**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
Location parameter (default=0).  
**Returns** **sf** : array\_like  
Survival function evaluated at  $k$ .

`rv_discrete.logsf(k, *args, **kws)`  
Log of the survival function of the given RV.  
Returns the log of the “survival function,” defined as  $1 - cdf$ , evaluated at  $k$ .

**Parameters** **k** : array\_like  
Quantiles.  
**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
Location parameter (default=0).  
**Returns** **logsf** : ndarray  
Log of the survival function evaluated at  $k$ .

`rv_discrete.ppf(q, *args, **kws)`  
Percent point function (inverse of  $cdf$ ) at  $q$  of the given RV.

**Parameters** **q** : array\_like  
Lower tail probability.  
**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
Location parameter (default=0).  
**Returns** **k** : array\_like

Quantile corresponding to the lower tail probability,  $q$ .

`rv_discrete.isf(q, *args, **kws)`

Inverse survival function (inverse of  $s_f$ ) at  $q$  of the given RV.

**Parameters** **q** : array\_like

Upper tail probability.

**arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional

Location parameter (default=0).

**Returns**

**k** : ndarray or scalar

Quantile corresponding to the upper tail probability,  $q$ .

`rv_discrete.moment(n, *args, **kws)`

$n$ -th order non-central moment of distribution.

**Parameters** **n** : int,  $n \geq 1$

Order of moment.

**arg1, arg2, arg3,...** : float

The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional

scale parameter (default=1)

`rv_discrete.stats(*args, **kws)`

Some statistics of the given RV.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional (continuous RVs only)

scale parameter (default=1)

**moments** : str, optional

composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's)

kurtosis. (default is 'mv')

**Returns**

**stats** : sequence

of requested moments.

`rv_discrete.entropy(*args, **kws)`

Differential entropy of the RV.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional

Location parameter (default=0).

**scale** : array\_like, optional (continuous distributions only).

Scale parameter (default=1).

**Notes**

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

`rv_discrete.expect` (*func=None, args=(), loc=0, lb=None, ub=None, conditional=False, maxcount=1000, tolerance=1e-10, chunksize=32*)

Calculate expected value of a function with respect to the distribution for discrete distribution.

**Parameters**

- func** : callable, optional  
Function for which the expectation value is calculated. Takes only one argument. The default is the identity mapping  $f(k) = k$ .
- args** : tuple, optional  
Shape parameters of the distribution.
- loc** : float, optional  
Location parameter. Default is 0.
- lb, ub** : int, optional  
Lower and upper bound for the summation, default is set to the support of the distribution, inclusive ( $ul \leq k \leq ub$ ).
- conditional** : bool, optional  
If true then the expectation is corrected by the conditional probability of the summation interval. The return value is the expectation of the function, *func*, conditional on being in the given interval ( $k$  such that  $ul \leq k \leq ub$ ). Default is False.
- maxcount** : int, optional  
Maximal number of terms to evaluate (to avoid an endless loop for an infinite sum). Default is 1000.
- tolerance** : float, optional  
Absolute tolerance for the summation. Default is 1e-10.
- chunksize** : int, optional  
Iterate over the support of a distributions in chunks of this size. Default is 32.

**Returns**

- expect** : float  
Expected value.

**Notes**

For heavy-tailed distributions, the expected value may or may not exist, depending on the function, *func*. If it does exist, but the sum converges slowly, the accuracy of the result may be rather low. For instance, for `zipf(4)`, accuracy for mean, variance in example is only 1e-5. increasing *maxcount* and/or *chunksize* may improve the result, but may also make `zipf` very slow.

The function is not vectorized.

`rv_discrete.median` (*\*args, \*\*kws*)

Median of the distribution.

**Parameters**

- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc** : array\_like, optional  
Location parameter, Default is 0.
- scale** : array\_like, optional  
Scale parameter, Default is 1.

**Returns**

- median** : float  
The median of the distribution.

See also:

***stats.distributions.rv\_discrete.ppf***

Inverse of the CDF

`rv_discrete.mean(*args, **kws)`

Mean of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **mean** : float  
 the mean of the distribution

`rv_discrete.std(*args, **kws)`

Standard deviation of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **std** : float  
 standard deviation of the distribution

`rv_discrete.var(*args, **kws)`

Variance of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **var** : float  
 the variance of the distribution

`rv_discrete.interval(alpha, *args, **kws)`

Confidence interval with equal areas around the median.

**Parameters** **alpha** : array\_like of float  
 Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].  
**arg1, arg2, ...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
 location parameter, Default is 0.  
**scale** : array\_like, optional  
 scale parameter, Default is 1.  
**Returns** **a, b** : ndarray of float  
 end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

`rv_discrete.__call__(*args, **kwargs)`

Freeze the distribution for the given arguments.

**Parameters** `arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns** `rv_frozen` : `rv_frozen` instance

The frozen distribution.

**class** `scipy.stats.rv_histogram`(*histogram*, \*args, \*\*kwargs)

Generates a distribution given by a histogram. This is useful to generate a template distribution from a binned datasample.

As a subclass of the `rv_continuous` class, `rv_histogram` inherits from it a collection of generic methods (see `rv_continuous` for the full list), and implements them based on the properties of the provided binned datasample.

**Parameters** `histogram` : tuple of array\_like

Tuple containing two array\_like objects The first containing the content of n bins The second containing the (n+1) bin boundaries In particular the return value `np.histogram` is accepted

### Notes

There are no additional shape parameters except for the `loc` and `scale`. The pdf is defined as a stepwise function from the provided histogram The cdf is a linear interpolation of the pdf.

New in version 0.19.0.

### Examples

Create a `scipy.stats` distribution from a numpy histogram

```
>>> import scipy.stats
>>> import numpy as np
>>> data = scipy.stats.norm.rvs(size=100000, loc=0, scale=1.5, random_state=123)
>>> hist = np.histogram(data, bins=100)
>>> hist_dist = scipy.stats.rv_histogram(hist)
```

Behaves like an ordinary `scipy rv_continuous` distribution

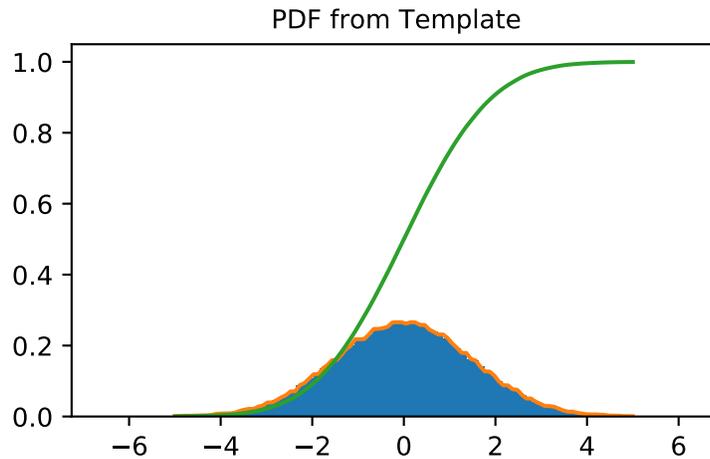

```
>>> hist_dist.pdf(1.0)
0.20538577847618705
>>> hist_dist.cdf(2.0)
0.90818568543056499
```

PDF is zero above (below) the highest (lowest) bin of the histogram, defined by the max (min) of the original dataset

```
>>> hist_dist.pdf(np.max(data))
0.0
>>> hist_dist.cdf(np.max(data))
1.0
>>> hist_dist.pdf(np.min(data))
7.7591907244498314e-05
>>> hist_dist.cdf(np.min(data))
0.0
```

PDF and CDF follow the histogram

```
>>> import matplotlib.pyplot as plt
>>> X = np.linspace(-5.0, 5.0, 100)
>>> plt.title("PDF from Template")
>>> plt.hist(data, normed=True, bins=100)
>>> plt.plot(X, hist_dist.pdf(X), label='PDF')
>>> plt.plot(X, hist_dist.cdf(X), label='CDF')
>>> plt.show()
```

**Attributes**

*random\_state* Get or set the RandomState object for generating random variates.

**rv\_histogram.random\_state**

Get or set the RandomState object for generating random variates.

This can be either None or an existing RandomState object.

If None (or np.random), use the RandomState singleton used by np.random. If already a RandomState instance, use it. If an int, use a new RandomState instance seeded with seed.

**Methods**

<i>__call__</i> (*args, **kwargs)	Freeze the distribution for the given arguments.
<i>cdf</i> (x, *args, **kwargs)	Cumulative distribution function of the given RV.
<i>entropy</i> (*args, **kwargs)	Differential entropy of the RV.
<i>expect</i> ([func, args, loc, scale, lb, ub, ...])	Calculate expected value of a function with respect to the distribution.
<i>fit</i> (data, *args, **kwargs)	Return MLEs for shape (if applicable), location, and scale parameters from data.
<i>fit_loc_scale</i> (data, *args)	Estimate loc and scale parameters from data using 1st and 2nd moments.
<i>freeze</i> (*args, **kwargs)	Freeze the distribution for the given arguments.
<i>interval</i> (alpha, *args, **kwargs)	Confidence interval with equal areas around the median.

<code>std(*args, **kws)</code>	Standard deviation of the distribution.
<code>var(*args, **kws)</code>	Variance of the distribution.

`rv_histogram.__call__(*args, **kws)`

Freeze the distribution for the given arguments.

**Parameters** `arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns** `rv_frozen` : `rv_frozen` instance

The frozen distribution.

`rv_histogram.cdf(x, *args, **kws)`

Cumulative distribution function of the given RV.

**Parameters** `x` : array\_like

quantiles

`arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

`loc` : array\_like, optional

location parameter (default=0)

`scale` : array\_like, optional

scale parameter (default=1)

**Returns** `cdf` : ndarray

Cumulative distribution function evaluated at *x*

`rv_histogram.entropy(*args, **kws)`

Differential entropy of the RV.

**Parameters** `arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information).

`loc` : array\_like, optional

Location parameter (default=0).

`scale` : array\_like, optional (continuous distributions only).

Scale parameter (default=1).

*Notes*

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

`rv_histogram.expect` (*func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, \*\*kwds*)

Calculate expected value of a function with respect to the distribution.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[x] = \int_{lb}^{ub} f(x) * dist.pdf(x)$$

- Parameters**
- func** : callable, optional  
Function for which integral is calculated. Takes only one argument. The default is the identity mapping  $f(x) = x$ .
  - args** : tuple, optional  
Shape parameters of the distribution.
  - loc** : float, optional  
Location parameter (default=0).
  - scale** : float, optional  
Scale parameter (default=1).
  - lb, ub** : scalar, optional  
Lower and upper bound for integration. Default is set to the support of the distribution.
  - conditional** : bool, optional  
If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.
- Returns**
- expect** : float  
**Additional keyword arguments are passed to the integration routine.**  
The calculated expected value.

*Notes*

The integration behavior of this function is inherited from `integrate.quad`.

`rv_histogram.fit` (*data, \*args, \*\*kwds*)

Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0, f1, ..., fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

- Parameters**
- data** : array\_like  
Data to use in calculating the MLEs.
  - args** : floats, optional  
Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.
  - kwds** : floats, optional

Starting values for the location and scale parameters; no default. Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
- `floc` : hold location parameter fixed to specified value.
- `fscale` : hold scale parameter fixed to specified value.
- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

**Returns** `mle_tuple` : tuple of floats

MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

### Notes

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

### Examples

Generate some data to fit: draw random variates from the *beta* distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

`rv_histogram.fit_loc_scale` (*data*, \**args*)

Estimate loc and scale parameters from data using 1st and 2nd moments.

**Parameters**

- data** : array\_like  
Data to fit.
- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**Returns**

- Lhat** : float  
Estimated location parameter for the data.
- Shat** : float  
Estimated scale parameter for the data.

`rv_histogram.freeze` (\**args*, \*\**kws*)

Freeze the distribution for the given arguments.

**Parameters**

- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns**

- rv\_frozen** : `rv_frozen` instance  
The frozen distribution.

`rv_histogram.interval` (*alpha*, \**args*, \*\**kws*)

Confidence interval with equal areas around the median.

**Parameters**

- alpha** : array\_like of float  
Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].
- arg1, arg2, ...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** : array\_like, optional  
location parameter, Default is 0.
- scale** : array\_like, optional  
scale parameter, Default is 1.

**Returns**

- a, b** : ndarray of float  
end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

`rv_histogram.isf` (*q*, \**args*, \*\**kws*)

Inverse survival function (inverse of  $s_f$ ) at *q* of the given RV.

**Parameters**

- q** : array\_like  
upper tail probability
- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc** : array\_like, optional  
location parameter (default=0)
- scale** : array\_like, optional  
scale parameter (default=1)

**Returns**

- x** : ndarray or scalar  
Quantile corresponding to the upper tail probability *q*.

`rv_histogram.logcdf` (*x*, \**args*, \*\**kws*)

Log of the cumulative distribution function at *x* of the given RV.

**Parameters**

- x** : array\_like  
quantiles
- arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **logcdf** : array\_like  
Log of the cumulative distribution function evaluated at x

`rv_histogram.logpdf(x, *args, **kwargs)`  
Log of the probability density function at x of the given RV.  
This uses a more numerically accurate calculation if available.

**Parameters** **x** : array\_like  
quantiles

**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **logpdf** : array\_like  
Log of the probability density function evaluated at x

`rv_histogram.logsf(x, *args, **kwargs)`  
Log of the survival function of the given RV.  
Returns the log of the “survival function,” defined as  $(1 - cdf)$ , evaluated at x.

**Parameters** **x** : array\_like  
quantiles

**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **logsf** : ndarray  
Log of the survival function evaluated at x.

`rv_histogram.mean(*args, **kwargs)`  
Mean of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **mean** : float  
the mean of the distribution

`rv_histogram.median(*args, **kwargs)`  
Median of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
Location parameter, Default is 0.

**scale** : array\_like, optional  
Scale parameter, Default is 1.

**Returns** **median** : float  
The median of the distribution.

**See also:**

***stats.distributions.rv\_discrete.ppf***

Inverse of the CDF

`rv_histogram.moment` (*n*, \*args, \*\*kwargs)  
n-th order non-central moment of distribution.

**Parameters** **n** : int, n >= 1  
Order of moment.

**arg1, arg2, arg3,...** : float  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

`rv_histogram.nnlf` (*theta*, *x*)  
Return negative loglikelihood function.

**Notes**

This is  $-\text{sum}(\log \text{pdf}(x, \text{theta}), \text{axis}=0)$  where *theta* are the parameters (including loc and scale).

`rv_histogram.pdf` (*x*, \*args, \*\*kwargs)  
Probability density function at x of the given RV.

**Parameters** **x** : array\_like  
quantiles

**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **pdf** : ndarray  
Probability density function evaluated at x

`rv_histogram.ppf` (*q*, \*args, \*\*kwargs)  
Percent point function (inverse of *cdf*) at q of the given RV.

**Parameters** **q** : array\_like  
lower tail probability

**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**Returns** **scale** : array\_like, optional  
 scale parameter (default=1)  
**x** : array\_like  
 quantile corresponding to the lower tail probability  $q$ .

`rv_histogram.rvs (*args, **kws)`  
 Random variates of given type.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
 Location parameter (default=0).  
**scale** : array\_like, optional  
 Scale parameter (default=1).  
**size** : int or tuple of ints, optional  
 Defining number of random variates (default is 1).  
**random\_state** : None or int or `np.random.RandomState` instance, optional  
 If int or `RandomState`, use it for drawing the random variates. If None, rely on `self.random_state`. Default is None.  
**Returns** **rvs** : ndarray or scalar  
 Random variates of given *size*.

`rv_histogram.sf (x, *args, **kws)`  
 Survival function ( $1 - cdf$ ) at  $x$  of the given RV.

**Parameters** **x** : array\_like  
 quantiles  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **sf** : array\_like  
 Survival function evaluated at  $x$

`rv_histogram.stats (*args, **kws)`  
 Some statistics of the given RV.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional (continuous RVs only)  
 scale parameter (default=1)  
**moments** : str, optional  
 composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')  
**Returns** **stats** : sequence  
 of requested moments.

`rv_histogram.std (*args, **kws)`  
 Standard deviation of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **std** : float  
standard deviation of the distribution

`rv_histogram.var(*args, **kws)`  
Variance of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **var** : float  
the variance of the distribution

### 5.27.1 Continuous distributions

<i>alpha</i>	An alpha continuous random variable.
<i>anglit</i>	An anglit continuous random variable.
<i>arcsine</i>	An arcsine continuous random variable.
<i>argus</i>	Argus distribution
<i>beta</i>	A beta continuous random variable.
<i>betaprime</i>	A beta prime continuous random variable.
<i>bradford</i>	A Bradford continuous random variable.
<i>burr</i>	A Burr (Type III) continuous random variable.
<i>burr12</i>	A Burr (Type XII) continuous random variable.
<i>cauchy</i>	A Cauchy continuous random variable.
<i>chi</i>	A chi continuous random variable.
<i>chi2</i>	A chi-squared continuous random variable.
<i>cosine</i>	A cosine continuous random variable.
<i>crystalball</i>	Crystalball distribution
<i>dgamma</i>	A double gamma continuous random variable.
<i>dweibull</i>	A double Weibull continuous random variable.
<i>erlang</i>	An Erlang continuous random variable.
<i>expon</i>	An exponential continuous random variable.
<i>exponnorm</i>	An exponentially modified Normal continuous random variable.
<i>exponweib</i>	An exponentiated Weibull continuous random variable.
<i>exponpow</i>	An exponential power continuous random variable.
<i>f</i>	An F continuous random variable.
<i>fatiguelife</i>	A fatigue-life (Birnbau-Saunders) continuous random variable.
<i>fisk</i>	A Fisk continuous random variable.
<i>foldcauchy</i>	A folded Cauchy continuous random variable.
<i>foldnorm</i>	A folded normal continuous random variable.

Continued on next page

Table 5.287 – continued from previous page

<i>frechet_r</i>	A frechet_r continuous random variable.
<i>frechet_l</i>	A frechet_l continuous random variable.
<i>genlogistic</i>	A generalized logistic continuous random variable.
<i>gennorm</i>	A generalized normal continuous random variable.
<i>genpareto</i>	A generalized Pareto continuous random variable.
<i>genexpon</i>	A generalized exponential continuous random variable.
<i>genextreme</i>	A generalized extreme value continuous random variable.
<i>gausshyper</i>	A Gauss hypergeometric continuous random variable.
<i>gamma</i>	A gamma continuous random variable.
<i>gengamma</i>	A generalized gamma continuous random variable.
<i>genhalflogistic</i>	A generalized half-logistic continuous random variable.
<i>gilbrat</i>	A Gilbrat continuous random variable.
<i>gompertz</i>	A Gompertz (or truncated Gumbel) continuous random variable.
<i>gumbel_r</i>	A right-skewed Gumbel continuous random variable.
<i>gumbel_l</i>	A left-skewed Gumbel continuous random variable.
<i>halfcauchy</i>	A Half-Cauchy continuous random variable.
<i>halflogistic</i>	A half-logistic continuous random variable.
<i>halfnorm</i>	A half-normal continuous random variable.
<i>halfgennorm</i>	The upper half of a generalized normal continuous random variable.
<i>hypsecant</i>	A hyperbolic secant continuous random variable.
<i>invgamma</i>	An inverted gamma continuous random variable.
<i>invgauss</i>	An inverse Gaussian continuous random variable.
<i>invweibull</i>	An inverted Weibull continuous random variable.
<i>johnsonsb</i>	A Johnson SB continuous random variable.
<i>johnsonsu</i>	A Johnson SU continuous random variable.
<i>kappa4</i>	Kappa 4 parameter distribution.
<i>kappa3</i>	Kappa 3 parameter distribution.
<i>ksone</i>	General Kolmogorov-Smirnov one-sided test.
<i>kstwobign</i>	Kolmogorov-Smirnov two-sided test for large N.
<i>laplace</i>	A Laplace continuous random variable.
<i>levy</i>	A Levy continuous random variable.
<i>levy_l</i>	A left-skewed Levy continuous random variable.
<i>levy_stable</i>	A Levy-stable continuous random variable.
<i>logistic</i>	A logistic (or Sech-squared) continuous random variable.
<i>loggamma</i>	A log gamma continuous random variable.
<i>loglaplace</i>	A log-Laplace continuous random variable.
<i>lognorm</i>	A lognormal continuous random variable.
<i>lomax</i>	A Lomax (Pareto of the second kind) continuous random variable.
<i>maxwell</i>	A Maxwell continuous random variable.
<i>mielke</i>	A Mielke's Beta-Kappa continuous random variable.
<i>nakagami</i>	A Nakagami continuous random variable.
<i>ncx2</i>	A non-central chi-squared continuous random variable.
<i>ncf</i>	A non-central F distribution continuous random variable.
<i>nct</i>	A non-central Student's T continuous random variable.
<i>norm</i>	A normal continuous random variable.
<i>pareto</i>	A Pareto continuous random variable.
<i>pearson3</i>	A pearson type III continuous random variable.

Continued on next page

Table 5.287 – continued from previous page

<i>powerlaw</i>	A power-function continuous random variable.
<i>powerlognorm</i>	A power log-normal continuous random variable.
<i>powernorm</i>	A power normal continuous random variable.
<i>rdist</i>	An R-distributed continuous random variable.
<i>reciprocal</i>	A reciprocal continuous random variable.
<i>rayleigh</i>	A Rayleigh continuous random variable.
<i>rice</i>	A Rice continuous random variable.
<i>recipinvgauss</i>	A reciprocal inverse Gaussian continuous random variable.
<i>semicircular</i>	A semicircular continuous random variable.
<i>skewnorm</i>	A skew-normal random variable.
<i>t</i>	A Student's T continuous random variable.
<i>trapz</i>	A trapezoidal continuous random variable.
<i>triang</i>	A triangular continuous random variable.
<i>truncexpon</i>	A truncated exponential continuous random variable.
<i>truncnorm</i>	A truncated normal continuous random variable.
<i>tukeylambda</i>	A Tukey-Lambda continuous random variable.
<i>uniform</i>	A uniform continuous random variable.
<i>vonmises</i>	A Von Mises continuous random variable.
<i>vonmises_line</i>	A Von Mises continuous random variable.
<i>wald</i>	A Wald continuous random variable.
<i>weibull_min</i>	Weibull minimum continuous random variable.
<i>weibull_max</i>	Weibull maximum continuous random variable.
<i>wrapcauchy</i>	A wrapped Cauchy continuous random variable.

`scipy.stats.alpha = <scipy.stats.continuous_distns.alpha_gen object>`

An alpha continuous random variable.

As an instance of the `rv_continuous` class, `alpha` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `alpha` is:

$$f(x, a) = \frac{1}{x^2 \Phi(a) \sqrt{2\pi}} * \exp\left(-\frac{1}{2}(a - 1/x)^2\right)$$

where  $\Phi(a)$  is the normal CDF,  $x > 0$ , and  $a > 0$ .

`alpha` takes `a` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `alpha.pdf(x, a, loc, scale)` is identically equivalent to `alpha.pdf(y, a) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import alpha
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 3.57
>>> mean, var, skew, kurt = alpha.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(alpha.ppf(0.01, a),
...                 alpha.ppf(0.99, a), 100)
>>> ax.plot(x, alpha.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='alpha pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = alpha(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

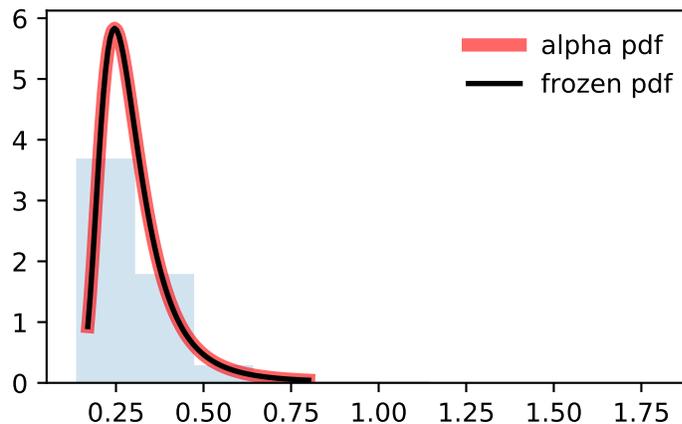

```
>>> vals = alpha.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], alpha.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = alpha.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.anqlit = <scipy.stats.continuous_distns.anqlit_gen object>`

An `anqlit` continuous random variable.

As an instance of the `rv_continuous` class, `anqlit` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `anqlit` is:

$$f(x) = \sin(2x + \pi/2) = \cos(2x)$$

for  $-\pi/4 \leq x \leq \pi/4$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `anqlit.pdf(x, loc, scale)` is identically equivalent to `anqlit.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import anqlit
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = anglit.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(anglit.ppf(0.01),
...                 anglit.ppf(0.99), 100)
>>> ax.plot(x, anglit.pdf(x),
...         'r-', lw=5, alpha=0.6, label='anglit pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = anglit()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

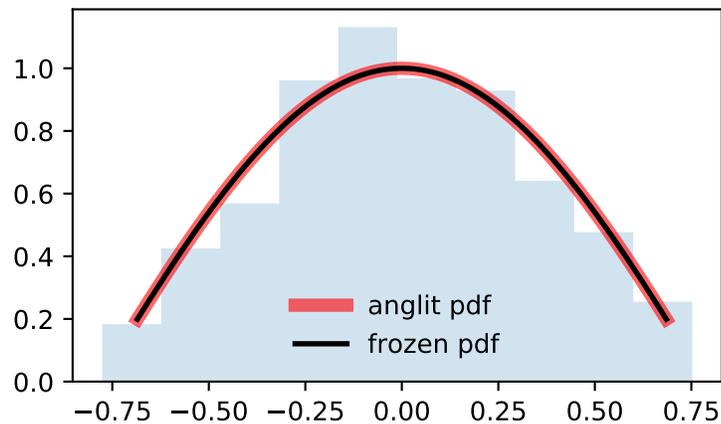

```
>>> vals = anglit.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], anglit.cdf(vals))
True
```

Generate random numbers:

```
>>> r = anglit.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.arcsine` = <scipy.stats\_continuous\_distns.arcsine\_gen object>

An arcsine continuous random variable.

As an instance of the `rv_continuous` class, `arcsine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `arcsine` is:

$$f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$$

for  $0 \leq x \leq 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `arcsine.pdf(x, loc, scale)` is identically equivalent to `arcsine.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import arcsine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = arcsine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(arcsine.ppf(0.01),
...                 arcsine.ppf(0.99), 100)
>>> ax.plot(x, arcsine.pdf(x),
...         'r-', lw=5, alpha=0.6, label='arcsine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = arcsine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

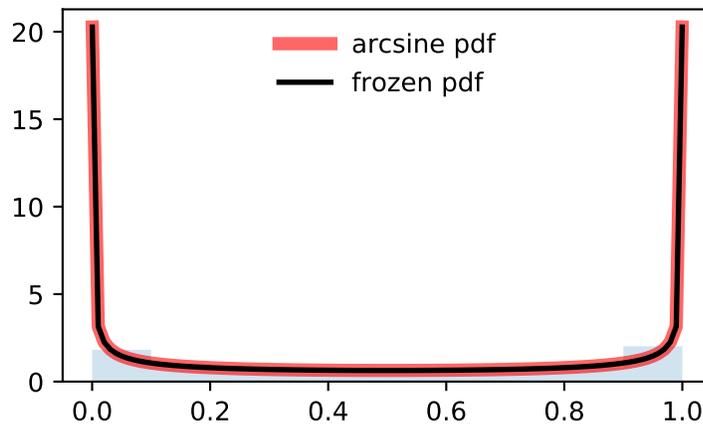

```
>>> vals = arcsine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], arcsine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = arcsine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.argus = <scipy.stats._continuous_distns.argus_gen object>`

Argus distribution

As an instance of the `rv_continuous` class, `argus` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `argus` is:

$$f(x, \chi) = \frac{\chi^3}{\sqrt{2\pi}\Psi(\chi)} x \sqrt{1-x^2} \exp(-0.5\chi^2(1-x^2))$$

where :

$$\Psi(\chi) = \Phi(\chi) - \chi\phi(\chi) - 1/2$$

with  $\Phi$  and  $\phi$  being the CDF and PDF of a standard normal distribution, respectively.

`argus` takes  $\chi$  as shape a parameter.

**References**

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `argus.pdf(x, chi, loc, scale)` is identically equivalent to `argus.pdf(y, chi) / scale` with  $y = (x - loc) / scale$ .

New in version 0.19.0.

[R609]

*Examples*

```
>>> from scipy.stats import argus
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> chi = 1
>>> mean, var, skew, kurt = argus.stats(chi, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(argus.ppf(0.01, chi),
...                 argus.ppf(0.99, chi), 100)
>>> ax.plot(x, argus.pdf(x, chi),
...         'r-', lw=5, alpha=0.6, label='argus pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = argus(chi)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

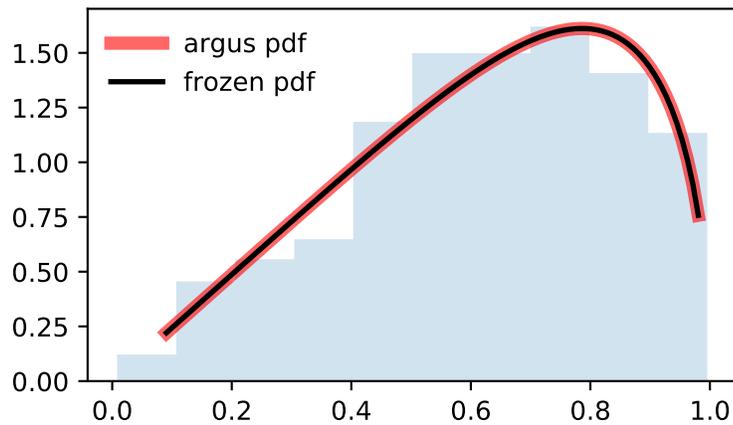

```
>>> vals = argus.ppf([0.001, 0.5, 0.999], chi)
>>> np.allclose([0.001, 0.5, 0.999], argus.cdf(vals, chi))
True
```

Generate random numbers:

```
>>> r = argus.rvs(chi, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(chi, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, chi, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, chi, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, chi, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, chi, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, chi, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, chi, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, chi, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, chi, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, chi, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(chi, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(chi, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, chi, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(chi,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(chi, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(chi, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(chi, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(chi, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, chi, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.beta = <scipy.stats_continuous_distns.beta_gen object>`

A beta continuous random variable.

As an instance of the *rv\_continuous* class, *beta* object inherits from it a collection of generic methods

(see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *beta* is:

$$f(x, a, b) = \frac{\gamma(a+b)x^{a-1}(1-x)^{b-1}}{\gamma(a)\gamma(b)}$$

for  $0 < x < 1$ ,  $a > 0$ ,  $b > 0$ , where  $\gamma(z)$  is the gamma function (`scipy.special.gamma`).

*beta* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `beta.pdf(x, a, b, loc, scale)` is identically equivalent to `beta.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import beta
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 2.31, 0.627
>>> mean, var, skew, kurt = beta.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(beta.ppf(0.01, a, b),
...                 beta.ppf(0.99, a, b), 100)
>>> ax.plot(x, beta.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='beta pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = beta(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

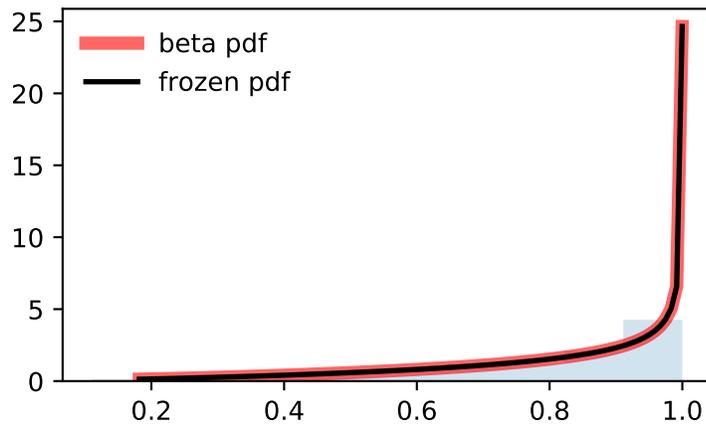

```
>>> vals = beta.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], beta.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = beta.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.betaprime = <scipy.stats.continuous_distns.betaprime_gen object>`

A beta prime continuous random variable.

As an instance of the *rv\_continuous* class, *betaprime* object inherits from it a collection of generic

methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *betaprime* is:

$$f(x, a, b) = \frac{x^{a-1}(1+x)^{-a-b}}{\beta(a, b)}$$

for  $x > 0, a > 0, b > 0$ , where  $\beta(a, b)$  is the beta function (see `scipy.special.beta`).

*betaprime* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `betaprime.pdf(x, a, b, loc, scale)` is identically equivalent to `betaprime.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import betaprime
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 5, 6
>>> mean, var, skew, kurt = betaprime.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(betaprime.ppf(0.01, a, b),
...                 betaprime.ppf(0.99, a, b), 100)
>>> ax.plot(x, betaprime.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='betaprime pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = betaprime(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

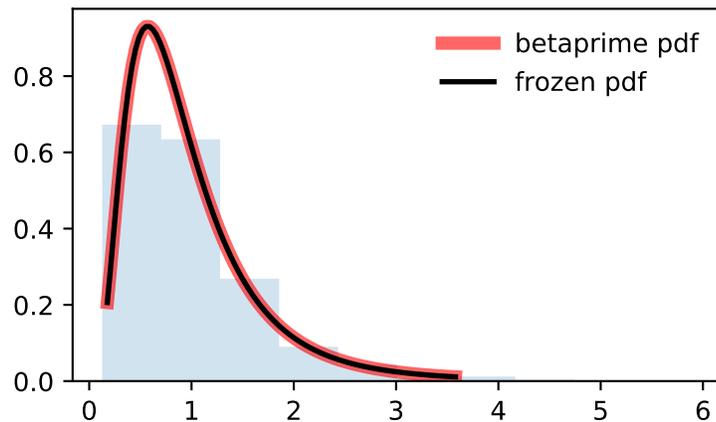

```
>>> vals = betaprime.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], betaprime.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = betaprime.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>

<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.bradford` = <scipy.stats.continuous\_distns.bradford\_gen object>

A Bradford continuous random variable.

As an instance of the *rv\_continuous* class, *bradford* object inherits from it a collection of generic meth-

ods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *bradford* is:

$$f(x, c) = \frac{c}{k(1 + cx)}$$

for  $0 < x < 1, c > 0$  and  $k = \log(1 + c)$ .

*bradford* takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `bradford.pdf(x, c, loc, scale)` is identically equivalent to `bradford.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import bradford
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.299
>>> mean, var, skew, kurt = bradford.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(bradford.ppf(0.01, c),
...                 bradford.ppf(0.99, c), 100)
>>> ax.plot(x, bradford.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='bradford pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = bradford(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

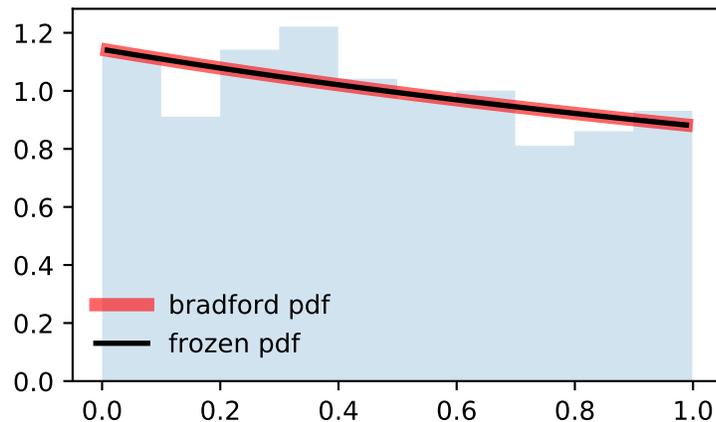

```
>>> vals = bradford.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], bradford.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = bradford.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.burr = <scipy.stats._continuous_distns.burr_gen object>`

A Burr (Type III) continuous random variable.

As an instance of the *rv\_continuous* class, *burr* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**fisk** a special case of either *burr* or *burr12* with  $d = 1$   
**burr12** Burr Type XII distribution

**Notes**

The probability density function for *burr* is:

$$f(x, c, d) = cdx^{-c-1}(1+x^{-c})^{-d-1}$$

for  $x > 0$ .

*burr* takes  $c$  and  $d$  as shape parameters.

This is the PDF corresponding to the third CDF given in Burr's list; specifically, it is equation (11) in Burr's paper [R615].

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `burr.pdf(x, c, d, loc, scale)` is identically equivalent to `burr.pdf(y, c, d) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**References**

[R615]

**Examples**

```
>>> from scipy.stats import burr
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 10.5, 4.3
>>> mean, var, skew, kurt = burr.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr.ppf(0.01, c, d),
...                 burr.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr.pdf(x, c, d),
...        'r-', lw=5, alpha=0.6, label='burr pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

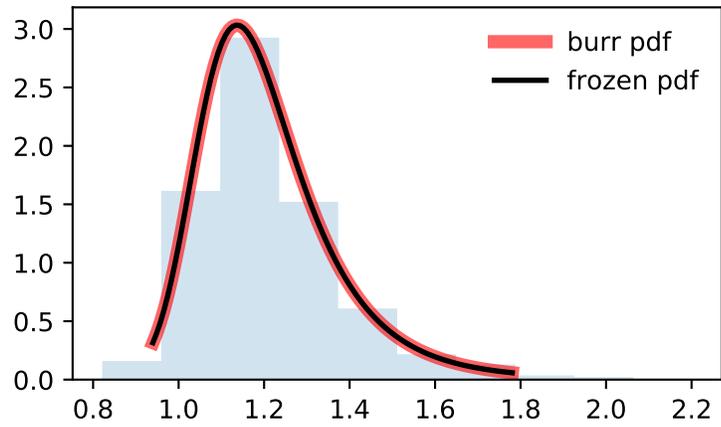

```
>>> vals = burr.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(c, d, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, d, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, d, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, d, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, d, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, d, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, d, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, d, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, d, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, d, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, d, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, d, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, d, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c, d), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, d, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, d, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, d, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, d, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, d, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.burr12 = <scipy.stats._continuous_distns.burr12_gen object>`

A Burr (Type XII) continuous random variable.

As an instance of the *rv\_continuous* class, *burr12* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**fisk** a special case of either *burr* or *burr12* with  $d = 1$   
**burr** Burr Type III distribution

**Notes**

The probability density function for *burr* is:

$$f(x, c, d) = cdx^{c-1}(1+x^c)^{-d-1}$$

for  $x > 0$ .

*burr12* takes *c* and *d* as shape parameters.

This is the PDF corresponding to the twelfth CDF given in Burr's list; specifically, it is equation (20) in Burr's paper [R616].

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `burr12.pdf(x, c, d, loc, scale)` is identically equivalent to `burr12.pdf(y, c, d) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

The Burr type 12 distribution is also sometimes referred to as the Singh-Maddala distribution from NIST [R617].

### References

[R616], [R617]

### Examples

```
>>> from scipy.stats import burr12
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 10, 4
>>> mean, var, skew, kurt = burr12.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr12.ppf(0.01, c, d),
...                 burr12.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr12.pdf(x, c, d),
...        'r-', lw=5, alpha=0.6, label='burr12 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr12(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

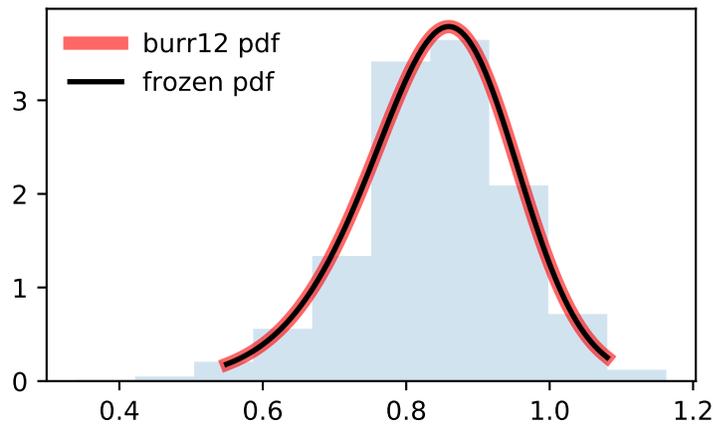

```
>>> vals = burr12.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr12.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr12.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

<code>sf(x, c, d, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, d, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, d, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, d, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, d, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, d, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, d, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, d, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c, d), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, d, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, d, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, d, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, d, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, d, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.cauchy` = <scipy.stats.continuous\_distns.cauchy\_gen object>

A Cauchy continuous random variable.

As an instance of the *rv\_continuous* class, *cauchy* object inherits from it a collection of generic methods

(see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *cauchy* is:

$$f(x) = \frac{1}{\pi(1+x^2)}$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cauchy.pdf(x, loc, scale)` is identically equivalent to `cauchy.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import cauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = cauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cauchy.ppf(0.01),
...                 cauchy.ppf(0.99), 100)
>>> ax.plot(x, cauchy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='cauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

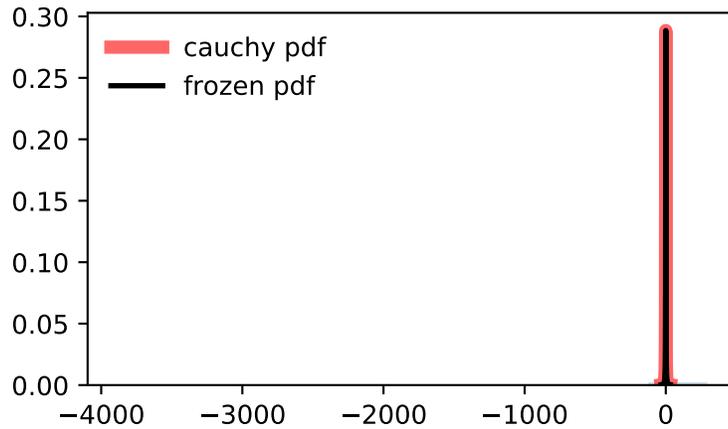

```
>>> vals = cauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.

<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.chi = <scipy.stats.continuous_distns.chi_gen object>`

A chi continuous random variable.

As an instance of the *rv\_continuous* class, *chi* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *chi* is:

$$f(x, df) = \frac{x^{df-1} \exp(-x^2/2)}{2^{df/2-1} \Gamma(df/2)}$$

for  $x > 0$ .

Special cases of *chi* are:

- `chi(1, loc, scale)` is equivalent to *halfnorm*
- `chi(2, 0, scale)` is equivalent to *rayleigh*
- `chi(3, 0, scale)` is equivalent to *maxwell*

*chi* takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi.pdf(x, df, loc, scale)` is identically equivalent to `chi.pdf(y, df) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import chi
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 78
>>> mean, var, skew, kurt = chi.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi.ppf(0.01, df),
...                 chi.ppf(0.99, df), 100)
>>> ax.plot(x, chi.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='chi pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

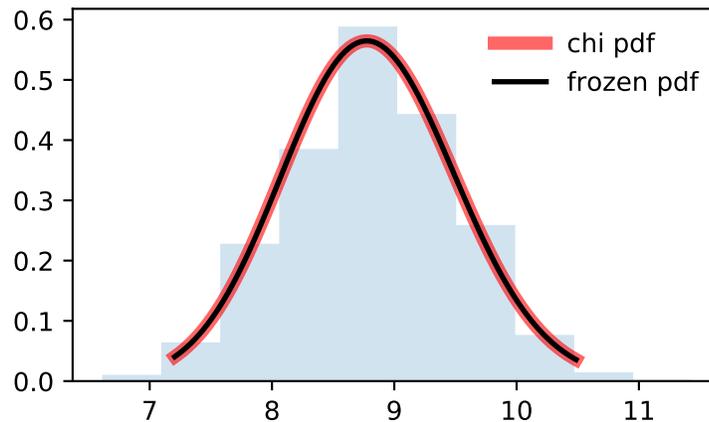

```
>>> vals = chi.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(df, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).

<code>fit(data, df, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.chi2` = <scipy.stats.continuous\_distns.chi2\_gen object>

A chi-squared continuous random variable.

As an instance of the *rv\_continuous* class, *chi2* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *chi2* is:

$$f(x, df) = \frac{1}{(2\gamma(df/2))} (x/2)^{df/2-1} \exp(-x/2)$$

*chi2* takes *df* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `chi2.pdf(x, df, loc, scale)` is identically equivalent to `chi2.pdf(y, df) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import chi2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 55
>>> mean, var, skew, kurt = chi2.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi2.ppf(0.01, df),
...                 chi2.ppf(0.99, df), 100)
>>> ax.plot(x, chi2.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='chi2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi2(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

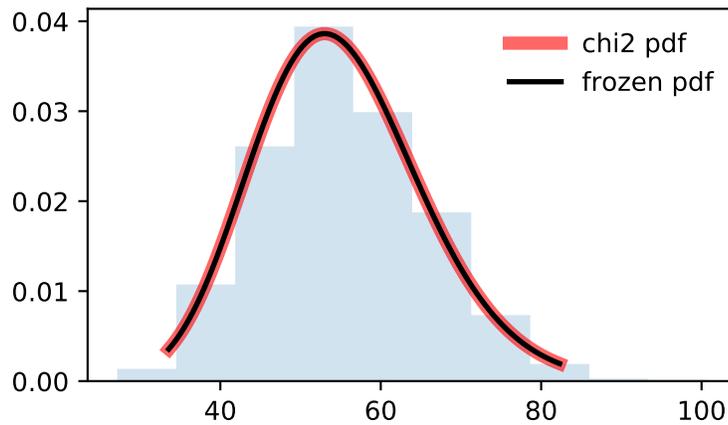

```
>>> vals = chi2.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi2.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi2.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(df, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, loc=0, scale=1)</code>	Log of the probability density function.

<code>interval(alpha, df, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.cosine = <scipy.stats.continuous_distns.cosine_gen object>`

A cosine continuous random variable.

As an instance of the *rv\_continuous* class, *cosine* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The cosine distribution is an approximation to the normal distribution. The probability density function for *cosine* is:

$$f(x) = \frac{1}{2\pi}(1 + \cos(x))$$

for  $-\pi \leq x \leq \pi$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cosine.pdf(x, loc, scale)` is identically equivalent to `cosine.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import cosine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = cosine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cosine.ppf(0.01),
...                 cosine.ppf(0.99), 100)
>>> ax.plot(x, cosine.pdf(x),
...        'r-', lw=5, alpha=0.6, label='cosine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cosine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

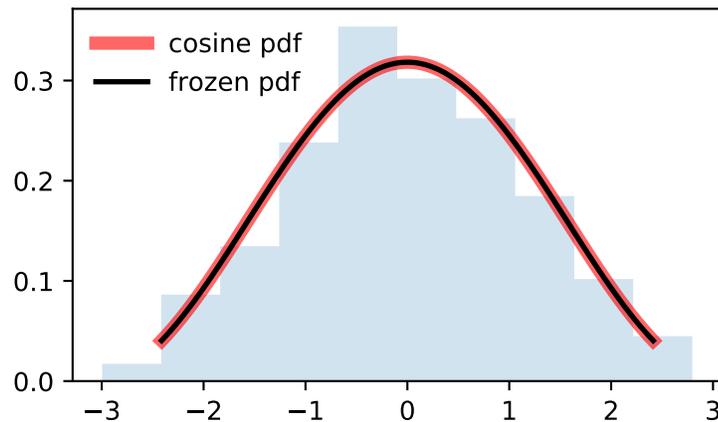

```
>>> vals = cosine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cosine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cosine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.crystalball = <scipy.stats.continuous_distns.crystalball_gen object>`

Crystalball distribution

As an instance of the *rv\_continuous* class, *crystalball* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `crystalball` is:

$$f(x, \beta, m) = \begin{cases} N \exp(-x^2/2), & \text{for } x > -\beta \\ NA(B - x)^{-m} & \text{for } x \leq -\beta \end{cases}$$

where  $A = (m/|\beta|) * n * \exp(-\beta^2/2)$ ,  $B = m/|\beta| - |\beta|$  and  $N$  is a normalisation constant.

`crystalball` takes  $\beta$  and  $m$  as shape parameters.  $\beta$  defines the point where the pdf changes from a power-law to a gaussian distribution  $m$  is power of the power-law tail.

### References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `crystalball.pdf(x, beta, m, loc, scale)` is identically equivalent to `crystalball.pdf(y, beta, m) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

[R628]

### Examples

```
>>> from scipy.stats import crystalball
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta, m = 2, 3
>>> mean, var, skew, kurt = crystalball.stats(beta, m, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(crystalball.ppf(0.01, beta, m),
...                 crystalball.ppf(0.99, beta, m), 100)
>>> ax.plot(x, crystalball.pdf(x, beta, m),
...         'r-', lw=5, alpha=0.6, label='crystalball pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = crystalball(beta, m)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

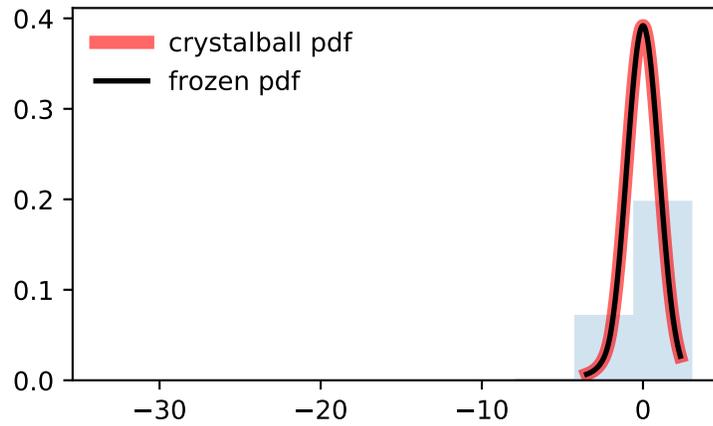

```
>>> vals = crystalball.ppf([0.001, 0.5, 0.999], beta, m)
>>> np.allclose([0.001, 0.5, 0.999], crystalball.cdf(vals, beta, m))
True
```

Generate random numbers:

```
>>> r = crystalball.rvs(beta, m, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(beta, m, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, beta, m, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, beta, m, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, beta, m, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, beta, m, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, beta, m, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, beta, m, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, beta, m, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, beta, m, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, beta, m, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(beta, m, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(beta, m, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, beta, m, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(beta, m), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(beta, m, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(beta, m, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(beta, m, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(beta, m, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, beta, m, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.dgamma = <scipy.stats._continuous_distns.dgamma_gen object>`

A double gamma continuous random variable.

As an instance of the `rv_continuous` class, `dgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `dgamma` is:

$$f(x, a) = \frac{1}{2\gamma(a)} |x|^{a-1} \exp(-|x|)$$

for  $a > 0$ .

`dgamma` takes  $a$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dgamma.pdf(x, a, loc, scale)` is identically equivalent to `dgamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import dgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.1
>>> mean, var, skew, kurt = dgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dgamma.ppf(0.01, a),
...                 dgamma.ppf(0.99, a), 100)
>>> ax.plot(x, dgamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='dgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

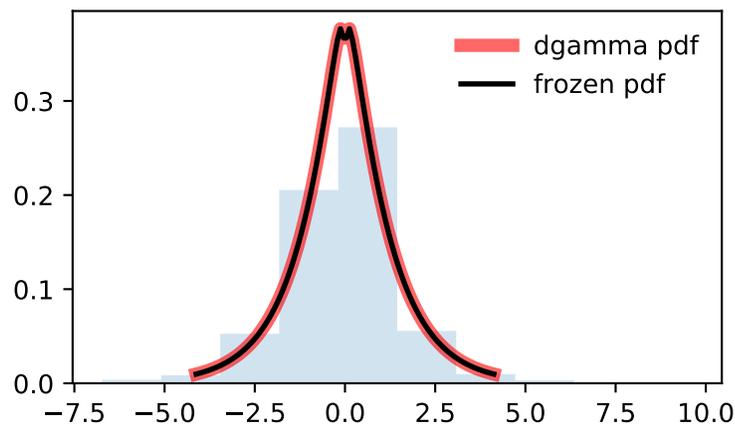

```
>>> vals = dgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], dgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = dgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.dweibull = <scipy.stats._continuous_distns.dweibull_gen object>`

A double Weibull continuous random variable.

As an instance of the *rv\_continuous* class, *dweibull* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *dweibull* is:

$$f(x, c) = c/2|x|^{c-1} \exp(-|x|^c)$$

*dweibull* takes *d* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `dweibull.pdf(x, c, loc, scale)` is identically equivalent to `dweibull.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import dweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 2.07
>>> mean, var, skew, kurt = dweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dweibull.ppf(0.01, c),
...                 dweibull.ppf(0.99, c), 100)
>>> ax.plot(x, dweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='dweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

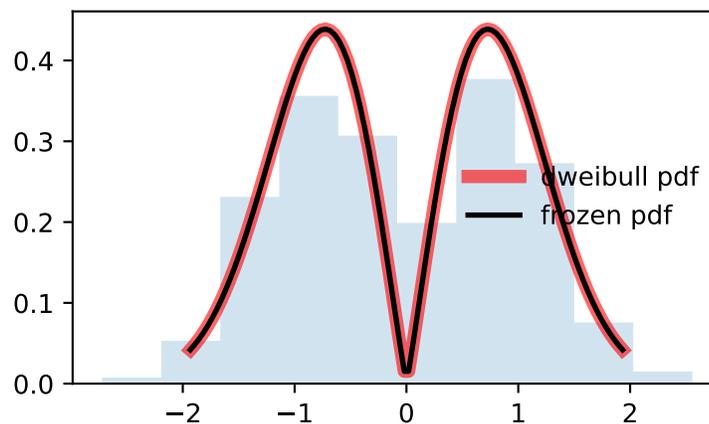

```
>>> vals = dweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], dweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = dweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.erlang = <scipy.stats_continuous_distns.erlang_gen object>`

An Erlang continuous random variable.

As an instance of the *rv\_continuous* class, *erlang* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

*gamma*

**Notes**

The Erlang distribution is a special case of the Gamma distribution, with the shape parameter *a* an integer. Note that this restriction is not enforced by *erlang*. It will, however, generate a warning the first time a non-integer value is used for the shape parameter.

Refer to *gamma* for examples.

**Methods**

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.expon` = <scipy.stats.continuous\_distns.expon\_gen object>

An exponential continuous random variable.

As an instance of the `rv_continuous` class, `expon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `expon` is:

$$f(x) = \exp(-x)$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `expon.pdf(x, loc, scale)` is identically equivalent to `expon.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

A common parameterization for `expon` is in terms of the rate parameter `lambda`, such that `pdf = lambda * exp(-lambda * x)`. This parameterization corresponds to using `scale = 1 / lambda`.

**Examples**

```
>>> from scipy.stats import expon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = expon.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(expon.ppf(0.01),
...                 expon.ppf(0.99), 100)
>>> ax.plot(x, expon.pdf(x),
...         'r-', lw=5, alpha=0.6, label='expon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = expon()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

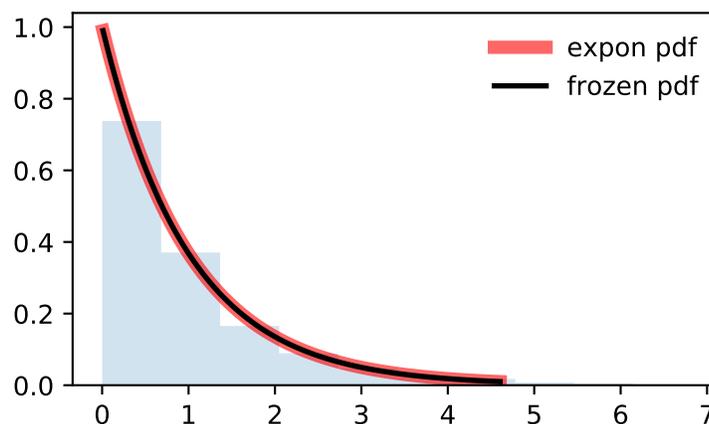

```
>>> vals = expon.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], expon.cdf(vals))
True
```

Generate random numbers:

```
>>> r = expon.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.exponnorm` = <scipy.stats.continuous\_distns.exponnorm\_gen object>

An exponentially modified Normal continuous random variable.

As an instance of the *rv\_continuous* class, *exponnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *exponnorm* is:

$$f(x, K) = \frac{1}{2K} \exp\left(\frac{1}{2K^2}\right) \exp(-x/K) \operatorname{erfc} - \frac{x - 1/K}{\sqrt{2}}$$

where the shape parameter  $K > 0$ .

It can be thought of as the sum of a normally distributed random value with mean *loc* and sigma *scale* and an exponentially distributed random number with a pdf proportional to  $\exp(-\text{lambda} * x)$  where  $\text{lambda} = (K * \text{scale})^{**}(-1)$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `exponnorm.pdf(x, K, loc, scale)` is identically equivalent to `exponnorm.pdf(y, K) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

An alternative parameterization of this distribution (for example, in [Wikipedia](#)) involves three parameters,  $\mu$ ,  $\lambda$  and  $\sigma$ . In the present parameterization this corresponds to having *loc* and *scale* equal to  $\mu$  and  $\sigma$ , respectively, and shape parameter  $K = 1/\sigma\lambda$ .

New in version 0.16.0.

### Examples

```
>>> from scipy.stats import exponnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> K = 1.5
>>> mean, var, skew, kurt = exponnorm.stats(K, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponnorm.ppf(0.01, K),
...                 exponnorm.ppf(0.99, K), 100)
>>> ax.plot(x, exponnorm.pdf(x, K),
...        'r-', lw=5, alpha=0.6, label='exponnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponnorm(K)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

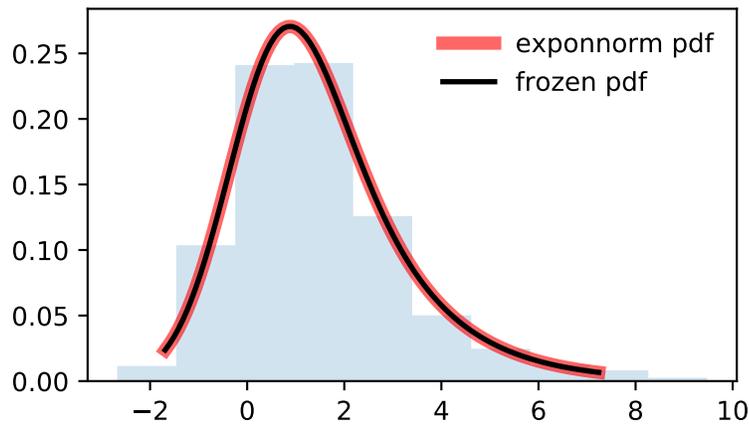

```
>>> vals = exponnorm.ppf([0.001, 0.5, 0.999], K)
>>> np.allclose([0.001, 0.5, 0.999], exponnorm.cdf(vals, K))
True
```

Generate random numbers:

```
>>> r = exponnorm.rvs(K, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(K, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, K, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, K, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, K, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, K, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, K, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, K, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, K, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, K, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, K, loc=0, scale=1)</code>	Non-central moment of order <i>n</i> .
<code>stats(K, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(K, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, K, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(K,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(K, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(K, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(K, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(K, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, K, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution.

`scipy.stats.exponweib` = <scipy.stats.continuous\_distns.exponweib\_gen object>

An exponentiated Weibull continuous random variable.

As an instance of the `rv_continuous` class, `exponweib` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *exponweib* is:

$$f(x, a, c) = ac(1 - \exp(-x^c))^{a-1} \exp(-x^c)x^{c-1}$$

for  $x > 0, a > 0, c > 0$ .

*exponweib* takes *a* and *c* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `exponweib.pdf(x, a, c, loc, scale)` is identically equivalent to `exponweib.pdf(y, a, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import exponweib
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, c = 2.89, 1.95
>>> mean, var, skew, kurt = exponweib.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponweib.ppf(0.01, a, c),
...                 exponweib.ppf(0.99, a, c), 100)
>>> ax.plot(x, exponweib.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='exponweib pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponweib(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

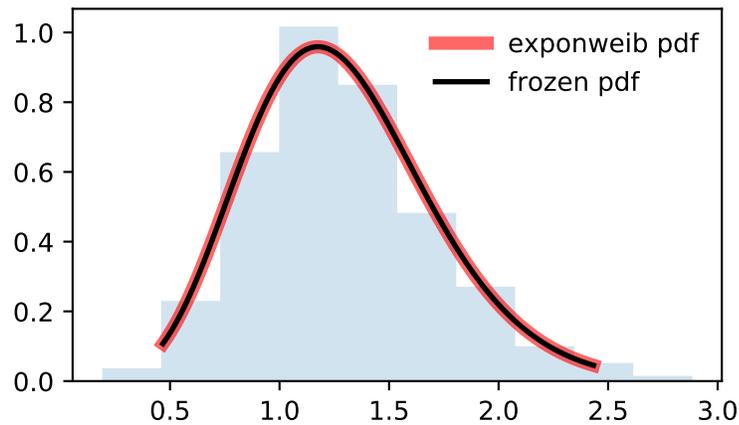

```
>>> vals = exponweib.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], exponweib.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = exponweib.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.exponpow = <scipy.stats.continuous_distns.exponpow_gen object>`

An exponential power continuous random variable.

As an instance of the *rv\_continuous* class, *exponpow* object inherits from it a collection of generic meth-

ods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `exponpow` is:

$$f(x, b) = bx^{b-1} \exp(1 + x^b - \exp(x^b))$$

for  $x \geq 0, b > 0$ . Note that this is a different distribution from the exponential power distribution that is also known under the names “generalized normal” or “generalized Gaussian”.

`exponpow` takes  $b$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponpow.pdf(x, b, loc, scale)` is identically equivalent to `exponpow.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### References

<http://www.math.wm.edu/~leemis/chart/UDR/PDFs/Exponentialpower.pdf>

### Examples

```
>>> from scipy.stats import exponpow
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 2.7
>>> mean, var, skew, kurt = exponpow.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponpow.ppf(0.01, b),
...                 exponpow.ppf(0.99, b), 100)
>>> ax.plot(x, exponpow.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='exponpow pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponpow(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

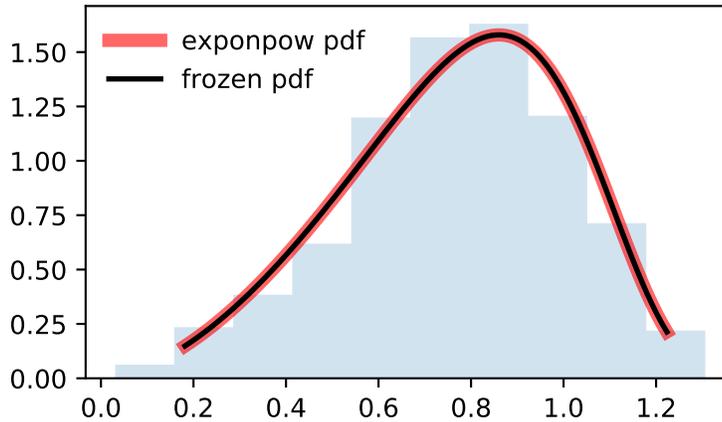

```
>>> vals = exponpow.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], exponpow.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = exponpow.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

`scipy.stats.f` = <scipy.stats\_continuous\_distns.f\_gen object>

An F continuous random variable.

As an instance of the `rv_continuous` class, `f` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `f` is:

$$f(x, df_1, df_2) = \frac{df_2^{df_2/2} df_1^{df_1/2} x^{df_1/2-1}}{(df_2 + df_1 x)^{(df_1+df_2)/2} B(df_1/2, df_2/2)}$$

for  $x > 0$ .

`f` takes `dfn` and `dfd` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `f.pdf(x, dfn, dfd, loc, scale)` is identically equivalent to `f.pdf(y, dfn, dfd) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import f
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> dfn, dfd = 29, 18
>>> mean, var, skew, kurt = f.stats(dfn, dfd, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(f.ppf(0.01, dfn, dfd),
...                 f.ppf(0.99, dfn, dfd), 100)
>>> ax.plot(x, f.pdf(x, dfn, dfd),
...         'r-', lw=5, alpha=0.6, label='f pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = f(dfn, dfd)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

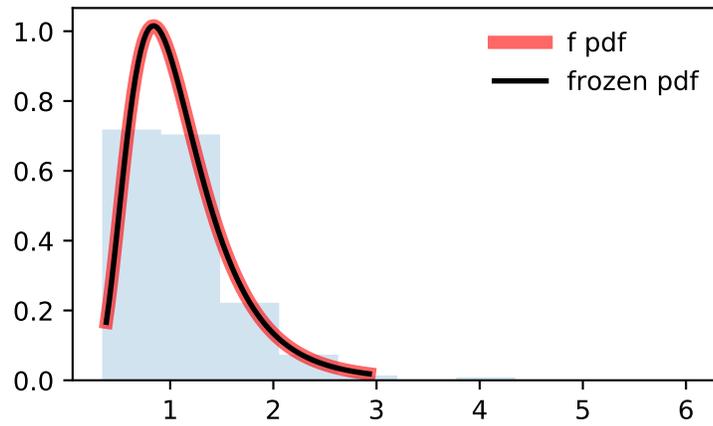

```
>>> vals = f.ppf([0.001, 0.5, 0.999], dfn, dfd)
>>> np.allclose([0.001, 0.5, 0.999], f.cdf(vals, dfn, dfd))
True
```

Generate random numbers:

```
>>> r = f.rvs(dfn, dfd, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(dfn, dfd, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, dfn, dfd, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, dfn, dfd, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, dfn, dfd, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, dfn, dfd, loc=0, scale=1)</code>	Log of the cumulative distribution function.

<code>median(dfn, dfd, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(dfn, dfd, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(dfn, dfd, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(dfn, dfd, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, dfn, dfd, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.fatiguelife = <scipy.stats.continuous_distns.fatiguelife_gen object>`

A fatigue-life (Birnbbaum-Saunders) continuous random variable.

As an instance of the *rv\_continuous* class, *fatiguelife* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *fatiguelife* is:

$$f(x, c) = \frac{x + 1}{2c\sqrt{2\pi}x^3 \exp\left(-\frac{(x-1)^2}{2xc^2}\right)}$$

for  $x > 0$ .

*fatiguelife* takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `fatiguelife.pdf(x, c, loc, scale)` is identically equivalent to `fatiguelife.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**References**

[R636]

*Examples*

```
>>> from scipy.stats import fatiguelife
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 29
>>> mean, var, skew, kurt = fatiguelife.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fatiguelife.ppf(0.01, c),
...                 fatiguelife.ppf(0.99, c), 100)
>>> ax.plot(x, fatiguelife.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fatiguelife pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fatiguelife(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

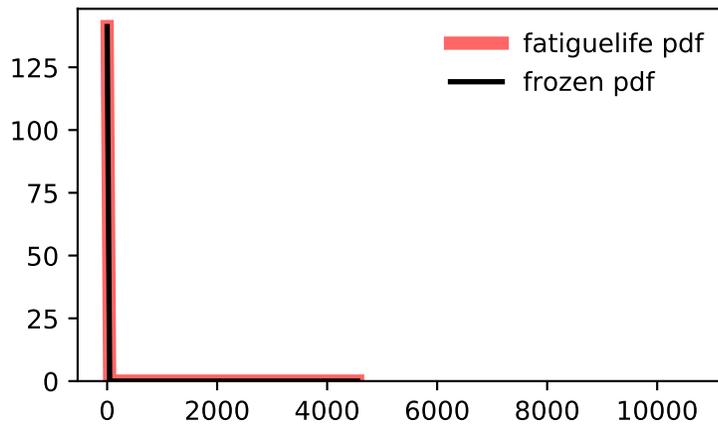

```
>>> vals = fatiguelife.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fatiguelife.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fatiguelife.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.fisk = <scipy.stats.continuous_distns.fisk_gen object>`

A Fisk continuous random variable.

The Fisk distribution is also known as the log-logistic distribution, and equals the Burr distribution with  $d == 1$ .

*fisk* takes *c* as a shape parameter.

As an instance of the *rv\_continuous* class, *fisk* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

*burr*

**Notes**

The probability density function for *fisk* is:

$$f(x, c) = cx^{-c-1}(1 + x^{-c})^{-2}$$

for  $x > 0$ .

*fisk* takes *c* as a shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `fisk.pdf(x, c, loc, scale)` is identically equivalent to `fisk.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import fisk
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.09
>>> mean, var, skew, kurt = fisk.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fisk.ppf(0.01, c),
...                 fisk.ppf(0.99, c), 100)
>>> ax.plot(x, fisk.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fisk pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fisk(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

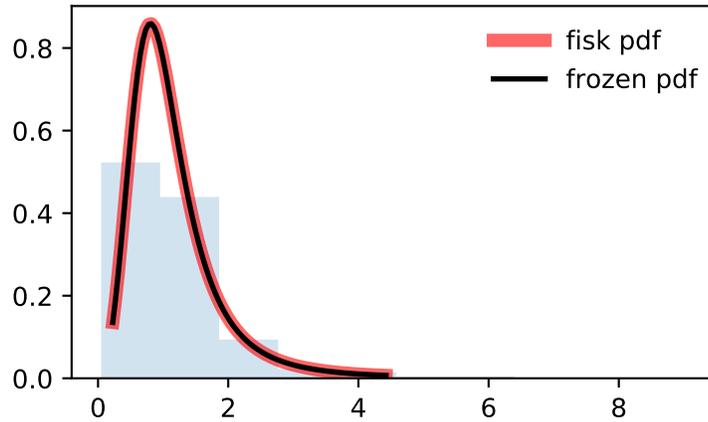

```
>>> vals = fisk.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fisk.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fisk.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

`scipy.stats.foldcauchy = <scipy.stats_continuous_distns.foldcauchy_gen object>`

A folded Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `foldcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `foldcauchy` is:

$$f(x, c) = \frac{1}{\pi(1 + (x - c)^2)} + \frac{1}{\pi(1 + (x + c)^2)}$$

for  $x \geq 0$ .

`foldcauchy` takes `c` as a shape parameter.

### Examples

```
>>> from scipy.stats import foldcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 4.72
>>> mean, var, skew, kurt = foldcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldcauchy.ppf(0.01, c),
...                 foldcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, foldcauchy.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='foldcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

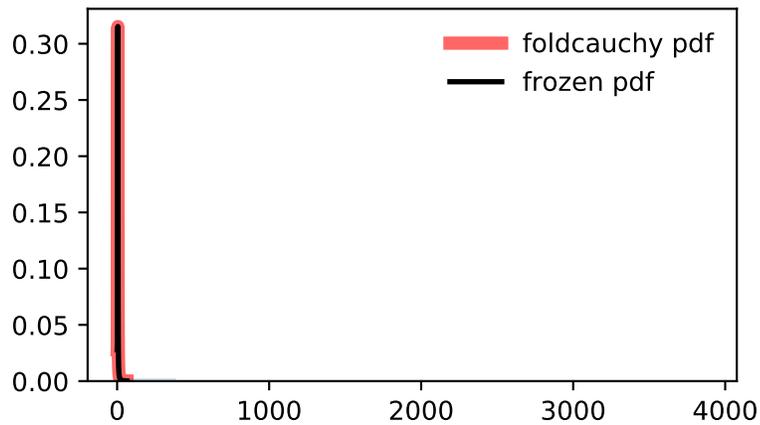

```
>>> vals = foldcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i> .
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution.

`scipy.stats.foldnorm = <scipy.stats._continuous_distns.foldnorm_gen object>`

A folded normal continuous random variable.

As an instance of the `rv_continuous` class, `foldnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `foldnorm` is:

$$f(x, c) = \sqrt{2/\pi} \cosh(cx) \exp\left(-\frac{x^2 + c^2}{2}\right)$$

for  $c \geq 0$ .

`foldnorm` takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `foldnorm.pdf(x, c, loc, scale)` is identically equivalent to `foldnorm.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import foldnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.95
>>> mean, var, skew, kurt = foldnorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldnorm.ppf(0.01, c),
...                 foldnorm.ppf(0.99, c), 100)
>>> ax.plot(x, foldnorm.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='foldnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldnorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

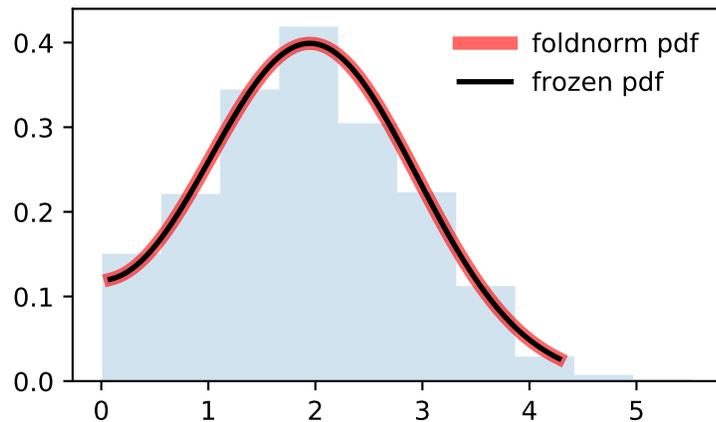

```
>>> vals = foldnorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldnorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldnorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.frechet_r = <scipy.stats.continuous_distns.frechet_r_gen object>`

A `frechet_r` continuous random variable.

As an instance of the `rv_continuous` class, `frechet_r` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

*Examples*

```
>>> from scipy.stats import frechet_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c =
>>> mean, var, skew, kurt = frechet_r.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(frechet_r.ppf(0.01, c),
...                 frechet_r.ppf(0.99, c), 100)
>>> ax.plot(x, frechet_r.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='frechet_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = frechet_r(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = frechet_r.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], frechet_r.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = frechet_r.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.frechet_1 = <scipy.stats.continuous_distns.frechet_1_gen object>`

A *frechet\_1* continuous random variable.

As an instance of the *rv\_continuous* class, *frechet\_1* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```
>>> from scipy.stats import frechet_1
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c =
>>> mean, var, skew, kurt = frechet_1.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(frechet_1.ppf(0.01, c),
...                 frechet_1.ppf(0.99, c), 100)
>>> ax.plot(x, frechet_1.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='frechet_1 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = frechet_1(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = frechet_1.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], frechet_1.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = frechet_1.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.genlogistic` = <scipy.stats.continuous\_distns.genlogistic\_gen object>

A generalized logistic continuous random variable.

As an instance of the `rv_continuous` class, `genlogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *genlogistic* is:

$$f(x, c) = c \frac{\exp(-x)}{(1 + \exp(-x))^{c+1}}$$

for  $x > 0, c > 0$ .

*genlogistic* takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genlogistic.pdf(x, c, loc, scale)` is identically equivalent to `genlogistic.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import genlogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.412
>>> mean, var, skew, kurt = genlogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genlogistic.ppf(0.01, c),
...                 genlogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genlogistic.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='genlogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genlogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

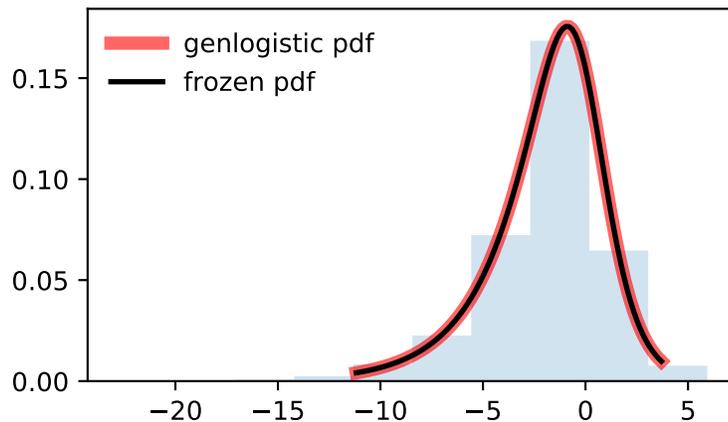

```
>>> vals = genlogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genlogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genlogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.gennorm` = <scipy.stats.continuous\_distns.gennorm\_gen object>

A generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `gennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

**laplace** Laplace distribution  
**norm** normal distribution

*Notes*

The probability density function for *gennorm* is [R646]:

$$\text{gennorm.pdf}(x, \text{beta}) = \frac{\text{beta}}{2 \text{ gamma}(1/\text{beta})} \exp(-|x|**\text{beta})$$

*gennorm* takes  $\beta$  as a shape parameter. For  $\beta = 1$ , it is identical to a Laplace distribution. For  $\beta = 2$ , it is identical to a normal distribution (with *scale* =  $1/\sqrt{2}$ ).

*References*

[R646]

*Examples*

```
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta = 1.3
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gennorm.ppf(0.01, beta),
...                 gennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, gennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='gennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

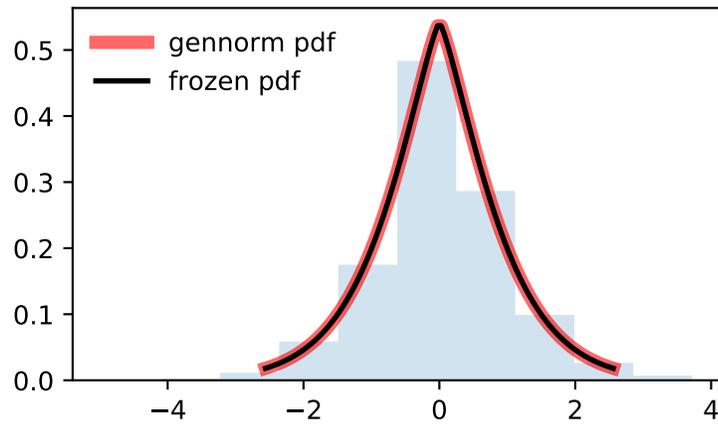

```
>>> vals = gennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], gennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = gennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(beta, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, beta, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, beta, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, beta, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, beta, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, beta, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, beta, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, beta, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).

<code>median(beta, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(beta, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(beta, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(beta, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, beta, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.genpareto` = <scipy.stats.continuous\_distns.genpareto\_gen object>

A generalized Pareto continuous random variable.

As an instance of the *rv\_continuous* class, *genpareto* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *genpareto* is:

$$f(x, c) = (1 + cx)^{-1-1/c}$$

defined for  $x \geq 0$  if  $c \geq 0$ , and for  $0 \leq x \leq -1/c$  if  $c < 0$ .

*genpareto* takes *c* as a shape parameter.

For  $c == 0$ , *genpareto* reduces to the exponential distribution, *expon*:

$$f(x, c = 0) = \exp(-x)$$

For  $c == -1$ , *genpareto* is uniform on  $[0, 1]$ :

$$f(x, c = -1) = x$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `genpareto.pdf(x, c, loc, scale)` is identically equivalent to `genpareto.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

*Examples*

```
>>> from scipy.stats import genpareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.1
>>> mean, var, skew, kurt = genpareto.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genpareto.ppf(0.01, c),
...                 genpareto.ppf(0.99, c), 100)
>>> ax.plot(x, genpareto.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genpareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genpareto(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

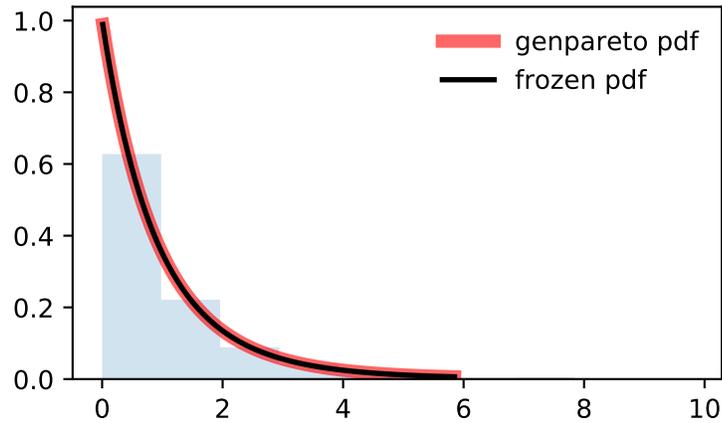

```
>>> vals = genpareto.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genpareto.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genpareto.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.genexpon = <scipy.stats._continuous_distns.genexpon_gen object>`

A generalized exponential continuous random variable.

As an instance of the `rv_continuous` class, `genexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *genexpon* is:

$$f(x, a, b, c) = (a + b(1 - \exp(-cx))) \exp(-ax - bx + \frac{b}{c}(1 - \exp(-cx)))$$

for  $x \geq 0, a, b, c > 0$ .

*genexpon* takes *a*, *b* and *c* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `genexpon.pdf(x, a, b, c, loc, scale)` is identically equivalent to `genexpon.pdf(y, a, b, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import genexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b, c = 9.13, 16.2, 3.28
>>> mean, var, skew, kurt = genexpon.stats(a, b, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genexpon.ppf(0.01, a, b, c),
...                 genexpon.ppf(0.99, a, b, c), 100)
>>> ax.plot(x, genexpon.pdf(x, a, b, c),
...        'r-', lw=5, alpha=0.6, label='genexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genexpon(a, b, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

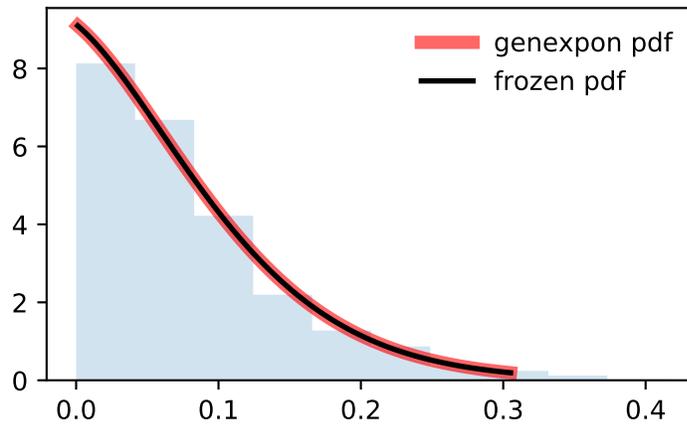

```
>>> vals = genexpon.ppf([0.001, 0.5, 0.999], a, b, c)
>>> np.allclose([0.001, 0.5, 0.999], genexpon.cdf(vals, a, b, c))
True
```

Generate random numbers:

```
>>> r = genexpon.rvs(a, b, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(a, b, c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.genextreme = <scipy.stats.continuous_distns.genextreme_gen object>`

A generalized extreme value continuous random variable.

As an instance of the *rv\_continuous* class, *genextreme* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

*gumbel\_r*

**Notes**

For  $c = 0$ , *genextreme* is equal to *gumbel\_r*. The probability density function for *genextreme* is:

$$f(x, c) = \begin{cases} \exp(-\exp(-x)) \exp(-x) & \text{for } c = 0 \\ \exp(-(1 - cx)^{1/c})(1 - cx)^{1/c-1} & \text{for } x \leq 1/c, c > 0 \end{cases}$$

Note that several sources and software packages use the opposite convention for the sign of the shape parameter *c*.

*genextreme* takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `genextreme.pdf(x, c, loc, scale)` is identically equivalent to `genextreme.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import genextreme
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = -0.1
>>> mean, var, skew, kurt = genextreme.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genextreme.ppf(0.01, c),
...                 genextreme.ppf(0.99, c), 100)
>>> ax.plot(x, genextreme.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='genextreme pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genextreme(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

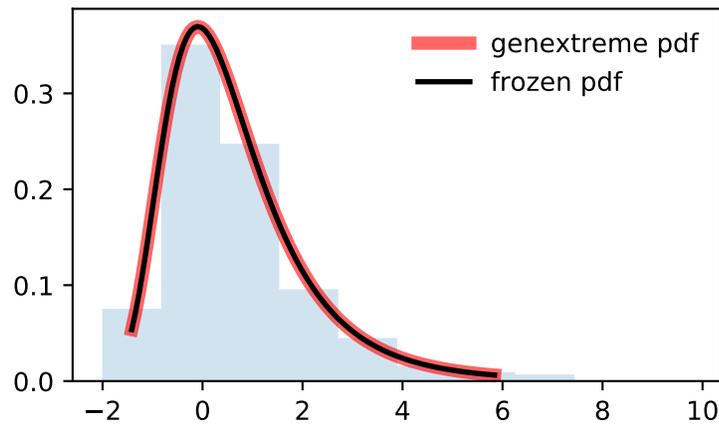

```
>>> vals = genextreme.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genextreme.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genextreme.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i> .
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution.

`scipy.stats.gausshyper = <scipy.stats._continuous_distns.gausshyper_gen object>`

A Gauss hypergeometric continuous random variable.

As an instance of the `rv_continuous` class, `gausshyper` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *gausshyper* is:

$$f(x, a, b, c, z) = Cx^{a-1}(1-x)^{b-1}(1+zx)^{-c}$$

for  $0 \leq x \leq 1$ ,  $a > 0$ ,  $b > 0$ , and  $C = \frac{1}{B(a,b)F[2,1](c,a;a+b;-z)}$

*gausshyper* takes *a*, *b*, *c* and *z* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `gausshyper.pdf(x, a, b, c, z, loc, scale)` is identically equivalent to `gausshyper.pdf(y, a, b, c, z) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import gausshyper
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b, c, z = 13.8, 3.12, 2.51, 5.18
>>> mean, var, skew, kurt = gausshyper.stats(a, b, c, z, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gausshyper.ppf(0.01, a, b, c, z),
...                 gausshyper.ppf(0.99, a, b, c, z), 100)
>>> ax.plot(x, gausshyper.pdf(x, a, b, c, z),
...         'r-', lw=5, alpha=0.6, label='gausshyper pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gausshyper(a, b, c, z)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

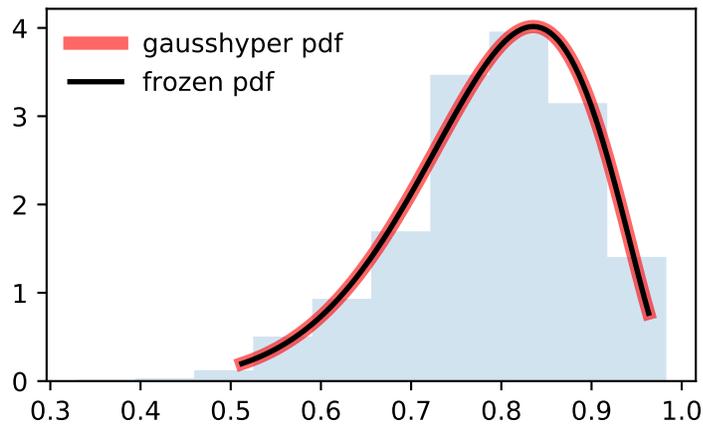

```
>>> vals = gausshyper.ppf([0.001, 0.5, 0.999], a, b, c, z)
>>> np.allclose([0.001, 0.5, 0.999], gausshyper.cdf(vals, a, b, c, z))
True
```

Generate random numbers:

```
>>> r = gausshyper.rvs(a, b, c, z, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, b, c, z, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, c, z, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, c, z, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, c, z, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, c, z, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, c, z, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, c, z, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, c, z, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, c, z, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, c, z, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, c, z, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, c, z, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, c, z, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b, c, z), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, c, z, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, c, z, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, c, z, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, c, z, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, c, z, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.gamma` = <scipy.stats\_continuous\_distns.gamma\_gen object>

A gamma continuous random variable.

As an instance of the `rv_continuous` class, `gamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`erlang`, `expon`

**Notes**

The probability density function for `gamma` is:

$$f(x, a) = \frac{x^{a-1} \exp(-x)}{\gamma(a)}$$

for  $x \geq 0$ ,  $a > 0$ . Here  $\gamma(a)$  refers to the gamma function.

`gamma` has a shape parameter  $a$  which needs to be set explicitly.

When  $a$  is an integer,  $\gamma$  reduces to the Erlang distribution, and when  $a = 1$  to the exponential distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gamma.pdf(x, a, loc, scale)` is identically equivalent to `gamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import gamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.99
>>> mean, var, skew, kurt = gamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gamma.ppf(0.01, a),
...                 gamma.ppf(0.99, a), 100)
>>> ax.plot(x, gamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='gamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

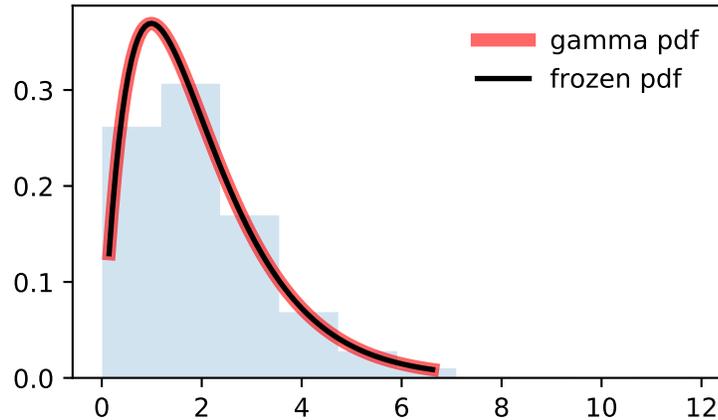

```
>>> vals = gamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], gamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = gamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.gengamma = <scipy.stats._continuous_distns.gengamma_gen object>`

A generalized gamma continuous random variable.

As an instance of the `rv_continuous` class, `gengamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `gengamma` is:

$$f(x, a, c) = \frac{|c|x^{ca-1} \exp(-x^c)}{\gamma(a)}$$

for  $x \geq 0$ ,  $a > 0$ , and  $c \neq 0$ .

`gengamma` takes  $a$  and  $c$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gengamma.pdf(x, a, c, loc, scale)` is identically equivalent to `gengamma.pdf(y, a, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import gengamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, c = 4.42, -3.12
>>> mean, var, skew, kurt = gengamma.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gengamma.ppf(0.01, a, c),
...                 gengamma.ppf(0.99, a, c), 100)
>>> ax.plot(x, gengamma.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='gengamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gengamma(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

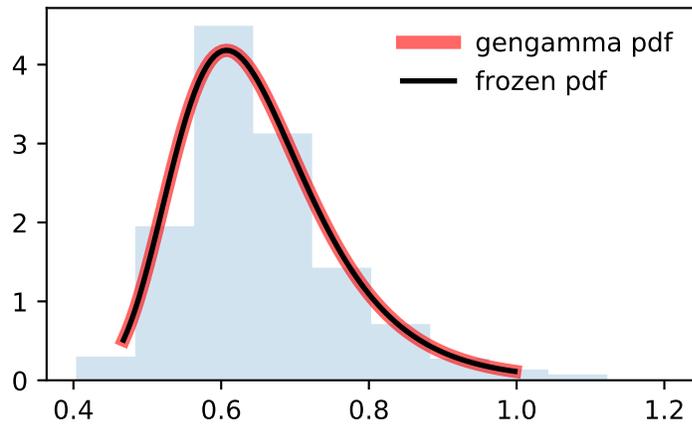

```
>>> vals = gengamma.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], gengamma.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = gengamma.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(a, c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, c, loc=0, scale=1)</code>	(Differential) entropy of the RV.

<code>expect(func, args=(a, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.genhalflogistic = <scipy.stats.continuous_distns.genhalflogistic_gen object>`

A generalized half-logistic continuous random variable.

As an instance of the *rv\_continuous* class, *genhalflogistic* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *genhalflogistic* is:

$$f(x, c) = \frac{2(1 - cx)^{1/(c-1)}}{[1 + (1 - cx)^{1/c}]^2}$$

for  $0 \leq x \leq 1/c$ , and  $c > 0$ .

*genhalflogistic* takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `genhalflogistic.pdf(x, c, loc, scale)` is identically equivalent to `genhalflogistic.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

*Examples*

```
>>> from scipy.stats import genhalflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.773
>>> mean, var, skew, kurt = genhalflogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genhalflogistic.ppf(0.01, c),
...                 genhalflogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genhalflogistic.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genhalflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genhalflogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

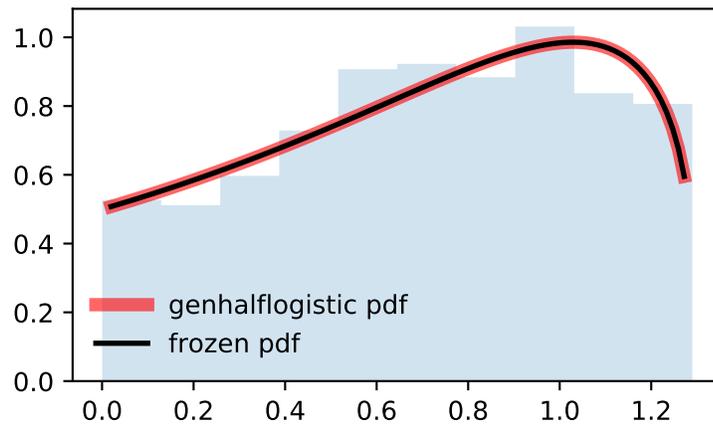

```
>>> vals = genhalflogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genhalflogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genhalflogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.gilbrat` = <scipy.stats.continuous\_distns.gilbrat\_gen object>

A Gilbrat continuous random variable.

As an instance of the *rv\_continuous* class, *gilbrat* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *gilbrat* is:

$$f(x) = \frac{1}{x\sqrt{2\pi}} \exp\left(-\frac{1}{2}(\log(x))^2\right)$$

*gilbrat* is a special case of *lognorm* with  $s = 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gilbrat.pdf(x, loc, scale)` is identically equivalent to `gilbrat.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import gilbrat
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gilbrat.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gilbrat.ppf(0.01),
...                 gilbrat.ppf(0.99), 100)
>>> ax.plot(x, gilbrat.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gilbrat pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gilbrat()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

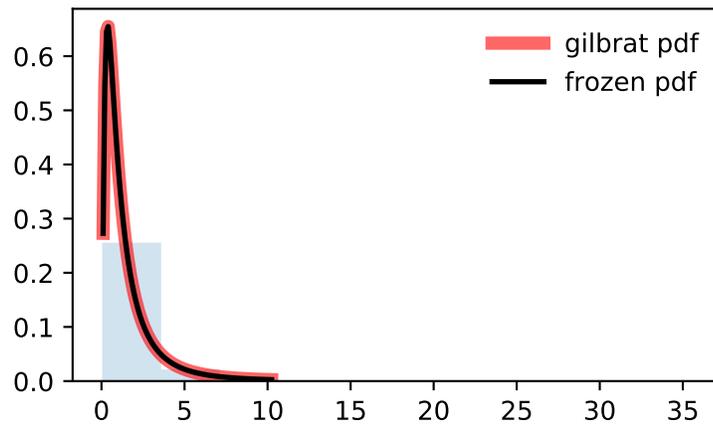

```
>>> vals = gilbrat.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gilbrat.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gilbrat.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.

<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.gompertz = <scipy.stats.continuous_distns.gompertz_gen object>`

A Gompertz (or truncated Gumbel) continuous random variable.

As an instance of the `rv_continuous` class, `gompertz` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *gompertz* is:

$$f(x, c) = c \exp(x) \exp(-c(e^x - 1))$$

for  $x \geq 0, c > 0$ .

*gompertz* takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gompertz.pdf(x, c, loc, scale)` is identically equivalent to `gompertz.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import gompertz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.947
>>> mean, var, skew, kurt = gompertz.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gompertz.ppf(0.01, c),
...                 gompertz.ppf(0.99, c), 100)
>>> ax.plot(x, gompertz.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='gompertz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gompertz(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

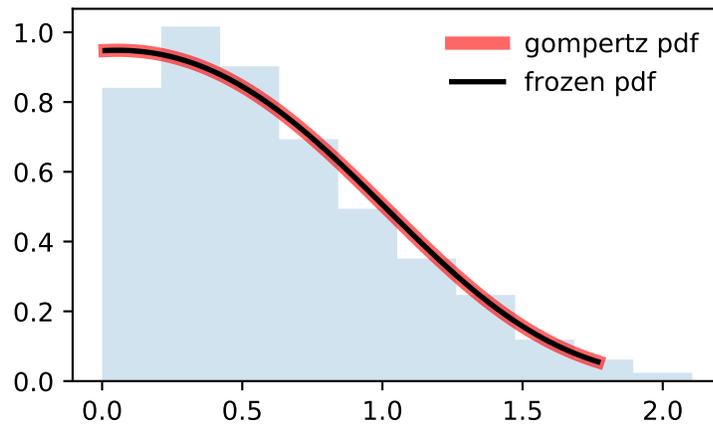

```
>>> vals = gompertz.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], gompertz.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = gompertz.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.gumbel_r` = <scipy.stats.continuous\_distns.gumbel\_r\_gen object>

A right-skewed Gumbel continuous random variable.

As an instance of the *rv\_continuous* class, *gumbel\_r* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

*gumbel\_l*, *gompertz*, *genextreme*

**Notes**

The probability density function for *gumbel\_r* is:

$$f(x) = \exp(-(x + e^{-x}))$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `gumbel_r.pdf(x, loc, scale)` is identically equivalent to `gumbel_r.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import gumbel_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gumbel_r.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_r.ppf(0.01),
...                 gumbel_r.ppf(0.99), 100)
>>> ax.plot(x, gumbel_r.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_r()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

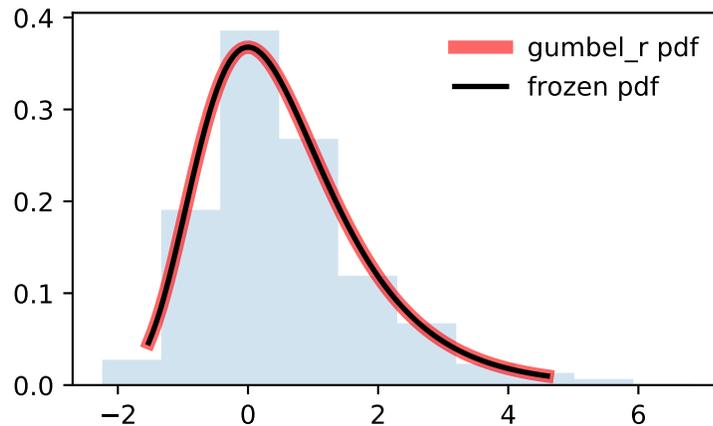

```
>>> vals = gumbel_r.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_r.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_r.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.gumbel_1 = <scipy.stats.continuous_distns.gumbel_1_gen object>`

A left-skewed Gumbel continuous random variable.

As an instance of the *rv\_continuous* class, *gumbel\_1* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`gumbel_r`, `gompertz`, `genextreme`

**Notes**

The probability density function for `gumbel_l` is:

$$f(x) = \exp(x - e^x)$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_l.pdf(x, loc, scale)` is identically equivalent to `gumbel_l.pdf(y) / scale` with `y = (x - loc) / scale`.

**Examples**

```
>>> from scipy.stats import gumbel_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gumbel_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_l.ppf(0.01),
...                 gumbel_l.ppf(0.99), 100)
>>> ax.plot(x, gumbel_l.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

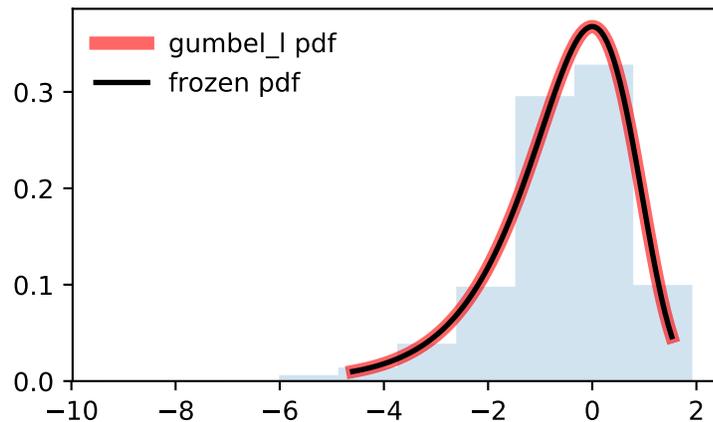

```
>>> vals = gumbel_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_l.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_l.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).

<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.halfcauchy = <scipy.stats._continuous_distns.halfcauchy_gen object>`

A Half-Cauchy continuous random variable.

As an instance of the *rv\_continuous* class, *halfcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *halfcauchy* is:

$$f(x) = \frac{2}{\pi(1+x^2)}$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfcauchy.pdf(x, loc, scale)` is identically equivalent to `halfcauchy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import halfcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halfcauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfcauchy.ppf(0.01),
...                 halfcauchy.ppf(0.99), 100)
>>> ax.plot(x, halfcauchy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halfcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfcauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

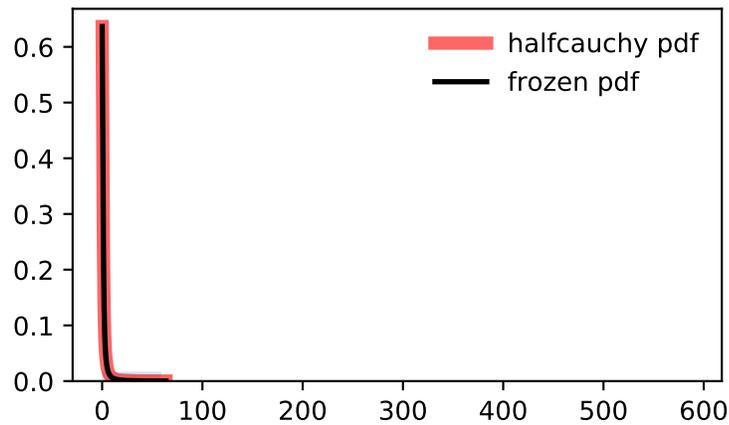

```
>>> vals = halfcauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfcauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfcauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.

<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.halflogistic = <scipy.stats._continuous_distns.halflogistic_gen object>`

A half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `halflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *halflogistic* is:

$$f(x) = \frac{2e^{-x}}{(1+e^{-x})^2} = \frac{1}{2} \operatorname{sech}(x/2)^2$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halflogistic.pdf(x, loc, scale)` is identically equivalent to `halflogistic.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import halflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halflogistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halflogistic.ppf(0.01),
...                 halflogistic.ppf(0.99), 100)
>>> ax.plot(x, halflogistic.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halflogistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

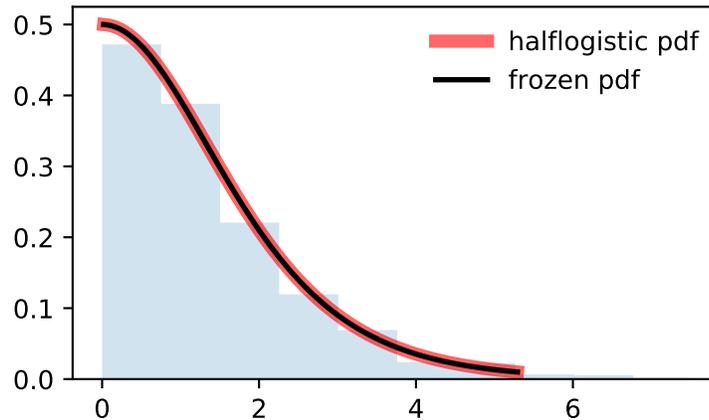

```
>>> vals = halflogistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halflogistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halflogistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.halfnorm = <scipy.stats._continuous_distns.halfnorm_gen object>`

A half-normal continuous random variable.

As an instance of the `rv_continuous` class, `halfnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *halfnorm* is:

$$f(x) = \sqrt{2/\pi} e^{-\frac{x^2}{2}}$$

for  $x > 0$ .

*halfnorm* is a special case of `math:chi` with `df == 1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfnorm.pdf(x, loc, scale)` is identically equivalent to `halfnorm.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import halfnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halfnorm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfnorm.ppf(0.01),
...                 halfnorm.ppf(0.99), 100)
>>> ax.plot(x, halfnorm.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halfnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfnorm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

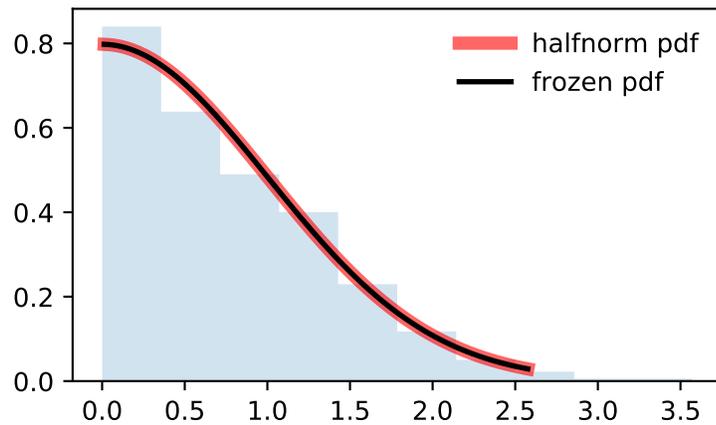

```
>>> vals = halfnorm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfnorm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfnorm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.halfgennorm = <scipy.stats.continuous_distns.halfgennorm_gen object>`

The upper half of a generalized normal continuous random variable.

As an instance of the *rv\_continuous* class, *halfgennorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**gennorm**    generalized normal distribution  
**expon**     exponential distribution  
**halfnorm**   half normal distribution

**Notes**

The probability density function for *halfgennorm* is:

$$f(x, \beta) = \frac{\beta}{\gamma(1/\beta)} \exp(-|x|^\beta)$$

*gennorm* takes  $\beta$  as a shape parameter. For  $\beta = 1$ , it is identical to an exponential distribution. For  $\beta = 2$ , it is identical to a half normal distribution (with *scale* =  $1/\sqrt{2}$ ).

**References**

[R647]

**Examples**

```
>>> from scipy.stats import halfgennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta = 0.675
>>> mean, var, skew, kurt = halfgennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfgennorm.ppf(0.01, beta),
...                 halfgennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, halfgennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='halfgennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfgennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

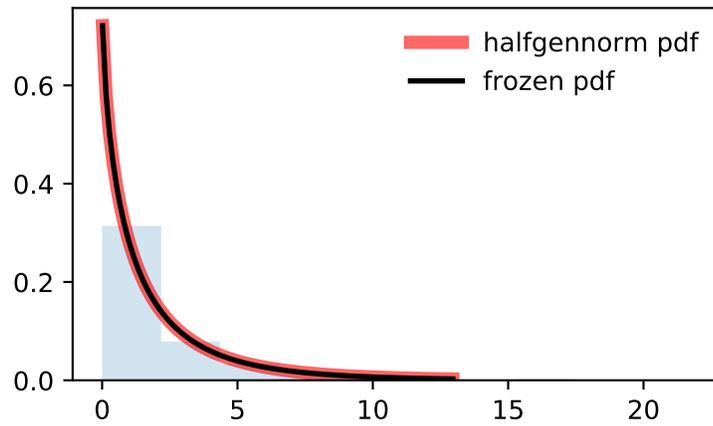

```
>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], halfgennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = halfgennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(beta, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, beta, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, beta, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, beta, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, beta, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, beta, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, beta, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, beta, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, beta, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, beta, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(beta, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(beta, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, beta, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(beta,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(beta, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(beta, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(beta, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(beta, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, beta, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.hypsecant` = <scipy.stats.continuous\_distns.hypsecant\_gen object>

A hyperbolic secant continuous random variable.

As an instance of the *rv\_continuous* class, *hypsecant* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *hypsecant* is:

$$f(x) = \frac{1}{\pi} \operatorname{sech}(x)$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `hypsecant.pdf(x, loc, scale)` is identically equivalent to `hypsecant.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import hypsecant
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = hypsecant.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(hypsecant.ppf(0.01),
...                 hypsecant.ppf(0.99), 100)
>>> ax.plot(x, hypsecant.pdf(x),
...         'r-', lw=5, alpha=0.6, label='hypsecant pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = hypsecant()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

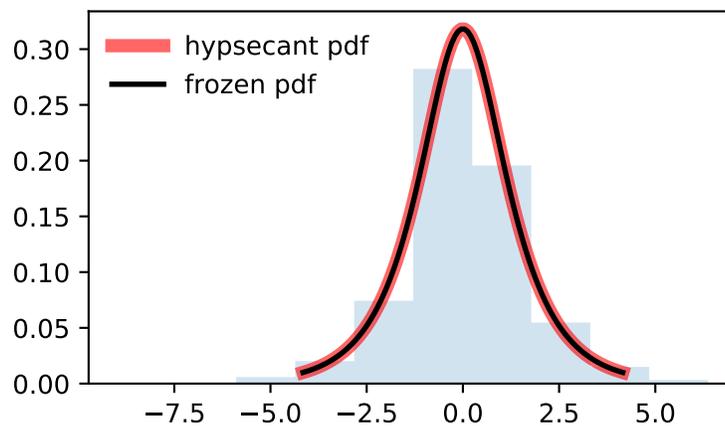

```
>>> vals = hypsecant.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], hypsecant.cdf(vals))
True
```

Generate random numbers:

```
>>> r = hypsecant.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.invgamma = <scipy.stats._continuous_distns.invgamma_gen object>`

An inverted gamma continuous random variable.

As an instance of the `rv_continuous` class, `invgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `invgamma` is:

$$f(x, a) = \frac{x^{-a-1}}{\gamma(a)} \exp\left(-\frac{1}{x}\right)$$

for  $x > 0, a > 0$ .

`invgamma` takes *a* as a shape parameter.

`invgamma` is a special case of `gengamma` with `c == -1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgamma.pdf(x, a, loc, scale)` is identically equivalent to `invgamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgamma.ppf(0.01, a),
...                 invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

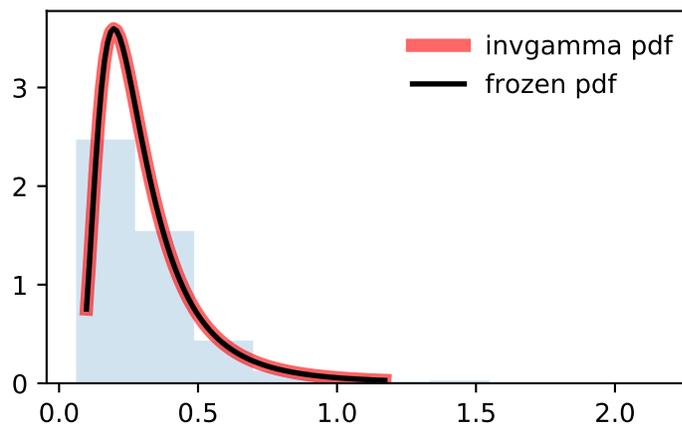

```
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = invgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.invgauss = <scipy.stats.continuous_distns.invgauss_gen object>`

An inverse Gaussian continuous random variable.

As an instance of the *rv\_continuous* class, *invgauss* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *invgauss* is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x - \mu)^2}{2x\mu^2}\right)$$

for  $x > 0$ .

*invgauss* takes  $\mu$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `invgauss.pdf(x, mu, loc, scale)` is identically equivalent to `invgauss.pdf(y, mu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

When  $\mu$  is too small, evaluating the cumulative distribution function will be inaccurate due to `cdf(mu -> 0) = inf * 0`. NaNs are returned for  $\mu \leq 0.0028$ .

**Examples**

```
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgauss.ppf(0.01, mu),
...                 invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu),
...         'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

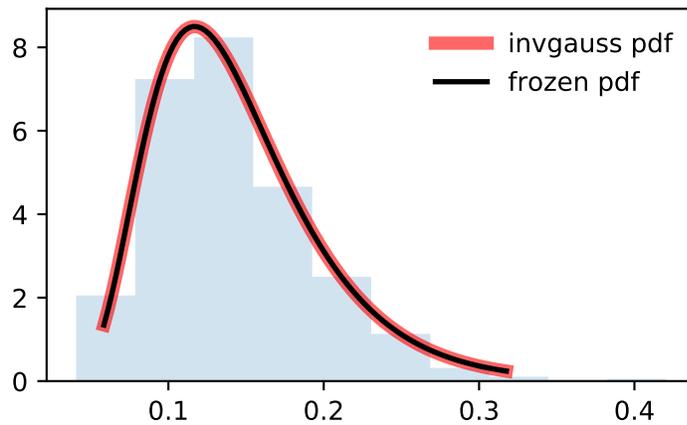

```
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = invgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(mu, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, mu, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, mu, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, mu, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, mu, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, mu, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, mu, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, mu, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, mu, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, mu, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(mu, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(mu, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, mu, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(mu, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(mu, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(mu, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(mu, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, mu, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.invweibull = <scipy.stats._continuous_distns.invweibull_gen object>`

An inverted Weibull continuous random variable.

As an instance of the *rv\_continuous* class, *invweibull* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *invweibull* is:

$$f(x, c) = cx^{-c-1} \exp(-x^{-c})$$

for  $x > 0$ ,  $c > 0$ .

*invweibull* takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invweibull.pdf(x, c, loc, scale)` is identically equivalent to `invweibull.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**References**

F.R.S. de Gusmao, E.M.M Ortega and G.M. Cordeiro, “The generalized inverse Weibull distribution”, Stat. Papers, vol. 52, pp. 591-619, 2011.

**Examples**

```
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invweibull.ppf(0.01, c),
...                 invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='invweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

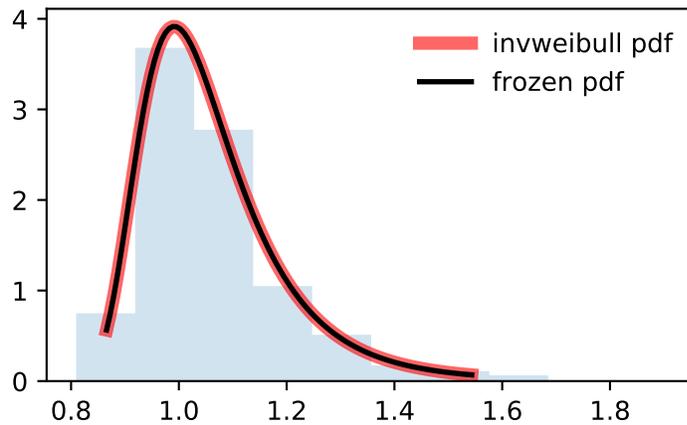

```
>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = invweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.johnsonsb` = <scipy.stats.continuous\_distns.johnsonsb\_gen object>

A Johnson SB continuous random variable.

As an instance of the *rv\_continuous* class, *johnsonsb* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:***johnsonsu***Notes**

The probability density function for *johnsonsb* is:

$$f(x, a, b) = \frac{b}{x(1-x)} \phi\left(a + b \log \frac{x}{1-x}\right)$$

for  $0 < x < 1$  and  $a, b > 0$ , and  $\phi$  is the normal pdf.

*johnsonsb* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `johnsonsb.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsb.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import johnsonsb
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 4.32, 3.18
>>> mean, var, skew, kurt = johnsonsb.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsb.ppf(0.01, a, b),
...                 johnsonsb.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsb.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsb(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

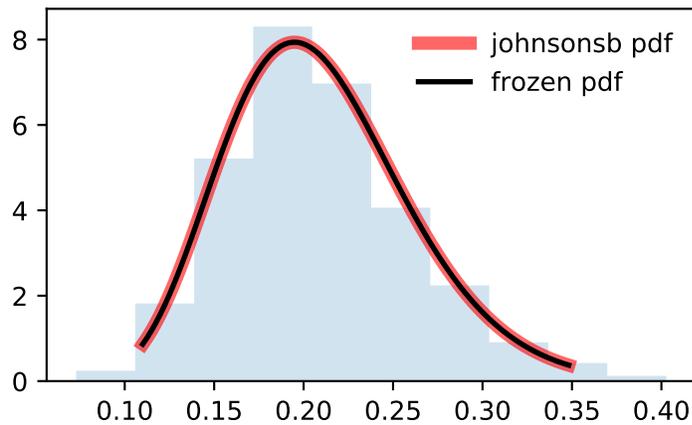

```
>>> vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsb.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.johnsonsu` = <scipy.stats\_continuous\_distns.johnsonsu\_gen object>

A Johnson SU continuous random variable.

As an instance of the *rv\_continuous* class, *johnsonsu* object inherits from it a collection of generic

methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

*johnsonsb*

**Notes**

The probability density function for *johnsonsu* is:

$$f(x, a, b) = \frac{b}{\sqrt{x^2 + 1}} \phi(a + b \log(x + \sqrt{x^2 + 1}))$$

for all  $x, a, b > 0$ , and  $\phi$  is the normal pdf.

*johnsonsu* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `johnsonsu.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsu.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b),
...                 johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

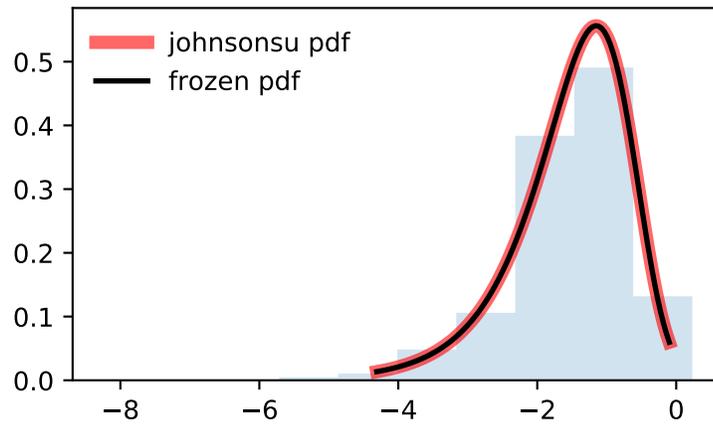

```
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsu.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.kappa4 = <scipy.stats._continuous_distns.kappa4_gen object>`

Kappa 4 parameter distribution.

As an instance of the *rv\_continuous* class, *kappa4* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *kappa4* is:

$$f(x, h, k) = (1 - kx)^{1/k-1} (1 - h(1 - kx)^{1/k})^{1/h-1}$$

if *h* and *k* are not equal to 0.

If *h* or *k* are zero then the pdf can be simplified:

*h* = 0 and *k* != 0:

```
kappa4.pdf(x, h, k) = (1.0 - k*x)**(1.0/k - 1.0)*
                    exp(-(1.0 - k*x)**(1.0/k))
```

*h* != 0 and *k* = 0:

```
kappa4.pdf(x, h, k) = exp(-x)*(1.0 - h*exp(-x))**(1.0/h - 1.0)
```

$h = 0$  and  $k = 0$ :

```
kappa4.pdf(x, h, k) = exp(-x)*exp(-exp(-x))
```

`kappa4` takes  $h$  and  $k$  as shape parameters.

The `kappa4` distribution returns other distributions when certain  $h$  and  $k$  values are used.

h	k=0.0	k=1.0	-inf<=k<=inf
-1.0	Logistic logistic(x)		Generalized Logistic(1)
0.0	Gumbel gumbel_r(x)	Reverse Exponential(2)	Generalized Extreme Value genextreme(x, k)
1.0	Exponential expon(x)	Uniform uniform(x)	Generalized Pareto genpareto(x, -k)

1. There are at least five generalized logistic distributions. Four are described here: [https://en.wikipedia.org/wiki/Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Generalized_logistic_distribution) The “fifth” one is the one `kappa4` should match which currently isn’t implemented in `scipy`: [https://en.wikipedia.org/wiki/Talk:Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Talk:Generalized_logistic_distribution) [http://www.mathwave.com/help/easyfit/html/analyses/distributions/gen\\_logistic.html](http://www.mathwave.com/help/easyfit/html/analyses/distributions/gen_logistic.html)

2. This distribution is currently not in `scipy`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa4.pdf(x, h, k, loc, scale)` is identically equivalent to `kappa4.pdf(y, h, k) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import kappa4
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> h, k = 0.1, 0
>>> mean, var, skew, kurt = kappa4.stats(h, k, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa4.ppf(0.01, h, k),
...                 kappa4.ppf(0.99, h, k), 100)
>>> ax.plot(x, kappa4.pdf(x, h, k),
...         'r-', lw=5, alpha=0.6, label='kappa4 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa4(h, k)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

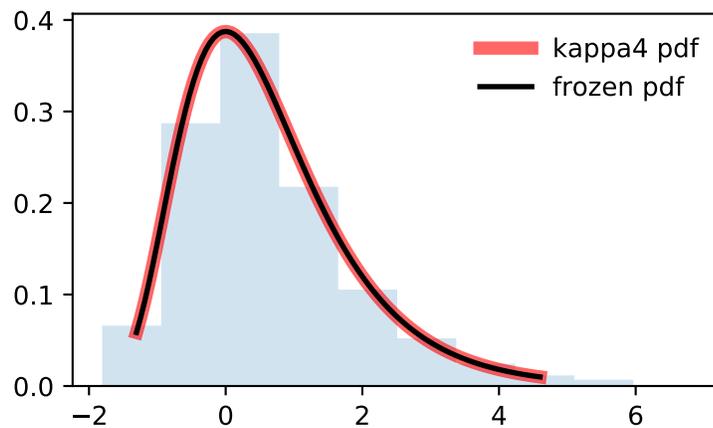

```
>>> vals = kappa4.ppf([0.001, 0.5, 0.999], h, k)
>>> np.allclose([0.001, 0.5, 0.999], kappa4.cdf(vals, h, k))
True
```

Generate random numbers:

```
>>> r = kappa4.rvs(h, k, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.kappa3 = <scipy.stats._continuous_distns.kappa3_gen object>`

Kappa 3 parameter distribution.

As an instance of the `rv_continuous` class, `kappa3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *kappa* is:

$$f(x, a) = \begin{cases} a[a + x^a]^{-(a+1)/a}, & \text{for } x > 0 \\ 0.0, & \text{for } x \leq 0 \end{cases}$$

`kappa3` takes *a* as a shape parameter and  $a > 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa3.pdf(x, a, loc, scale)` is identically equivalent to `kappa3.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import kappa3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1
>>> mean, var, skew, kurt = kappa3.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa3.ppf(0.01, a),
...                 kappa3.ppf(0.99, a), 100)
>>> ax.plot(x, kappa3.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='kappa3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa3(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

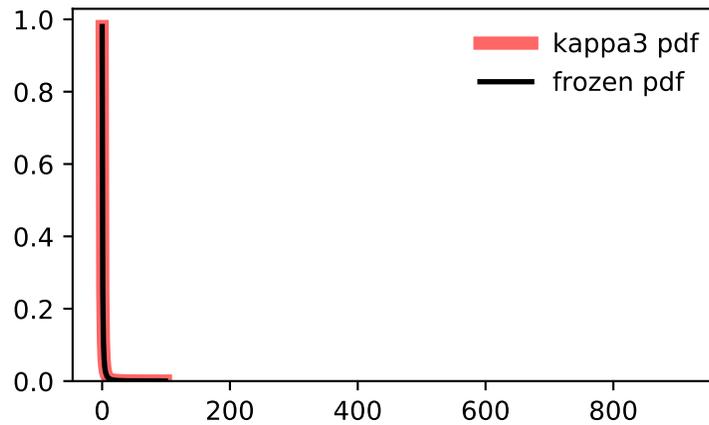

```
>>> vals = kappa3.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], kappa3.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = kappa3.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.kstone = <scipy.stats.continuous_distns.kstone_gen object>`

General Kolmogorov-Smirnov one-sided test.

As an instance of the *rv\_continuous* class, *kstone* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```
>>> from scipy.stats import ksone
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n = 1e+03
>>> mean, var, skew, kurt = ksone.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ksone.ppf(0.01, n),
...                 ksone.ppf(0.99, n), 100)
>>> ax.plot(x, ksone.pdf(x, n),
...         'r-', lw=5, alpha=0.6, label='ksone pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ksone(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

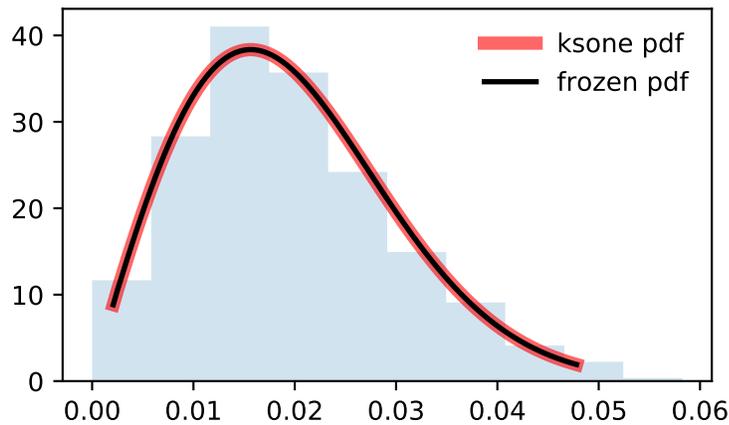

```
>>> vals = ksone.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], ksone.cdf(vals, n))
True
```

Generate random numbers:

```
>>> r = ksone.rvs(n, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.kstwobign` = <scipy.stats.\_continuous\_distns.kstwobign\_gen object>

Kolmogorov-Smirnov two-sided test for large *N*.

As an instance of the *rv\_continuous* class, *kstwobign* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```
>>> from scipy.stats import kstwobign
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = kstwobign.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kstwobign.ppf(0.01),
...                 kstwobign.ppf(0.99), 100)
>>> ax.plot(x, kstwobign.pdf(x),
...         'r-', lw=5, alpha=0.6, label='kstwobign pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kstwobign()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

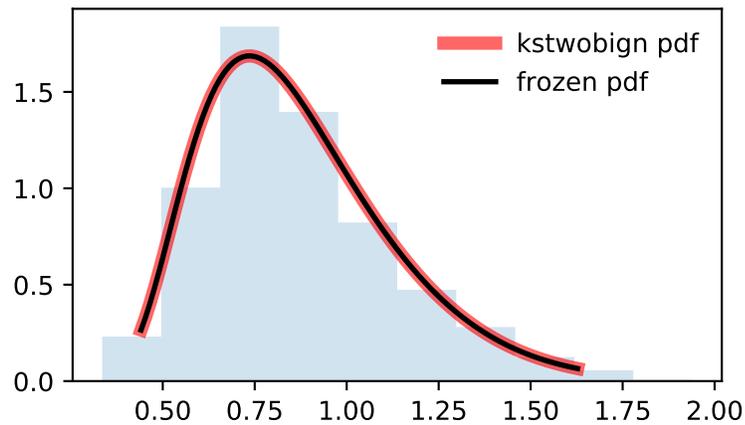

```
>>> vals = kstwobign.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], kstwobign.cdf(vals))
True
```

Generate random numbers:

```
>>> r = kstwobign.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.

`scipy.stats.laplace` = <scipy.stats.continuous\_distns.laplace\_gen object>

A Laplace continuous random variable.

As an instance of the *rv\_continuous* class, *laplace* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `laplace` is:

$$f(x) = \frac{1}{2} \exp(-|x|)$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `laplace.pdf(x, loc, scale)` is identically equivalent to `laplace.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import laplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = laplace.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(laplace.ppf(0.01),
...                 laplace.ppf(0.99), 100)
>>> ax.plot(x, laplace.pdf(x),
...         'r-', lw=5, alpha=0.6, label='laplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = laplace()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

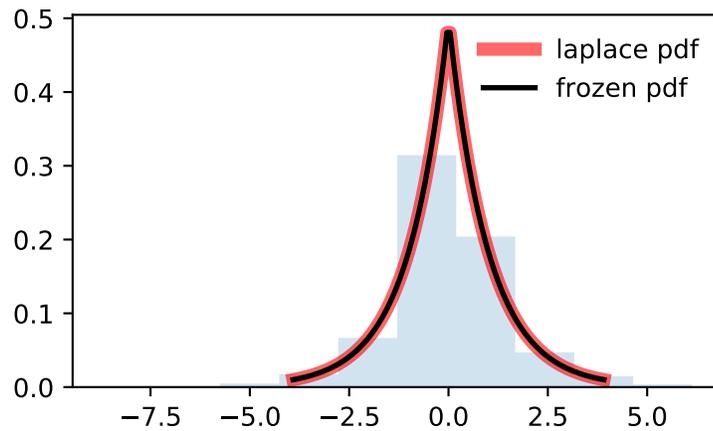

```
>>> vals = laplace.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], laplace.cdf(vals))
True
```

Generate random numbers:

```
>>> r = laplace.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.levy` = <scipy.stats.continuous\_distns.levy\_gen object>

A Levy continuous random variable.

As an instance of the *rv\_continuous* class, *levy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**`levy_stable, levy_l`**Notes**

The probability density function for `levy` is:

$$f(x) = \frac{1}{x\sqrt{2\pi x}} \exp\left(-\frac{1}{2x}\right)$$

for  $x > 0$ .

This is the same as the Levy-stable distribution with  $a = 1/2$  and  $b = 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy.pdf(x, loc, scale)` is identically equivalent to `levy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import levy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = levy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy.ppf(0.01),
...                 levy.ppf(0.99), 100)
>>> ax.plot(x, levy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

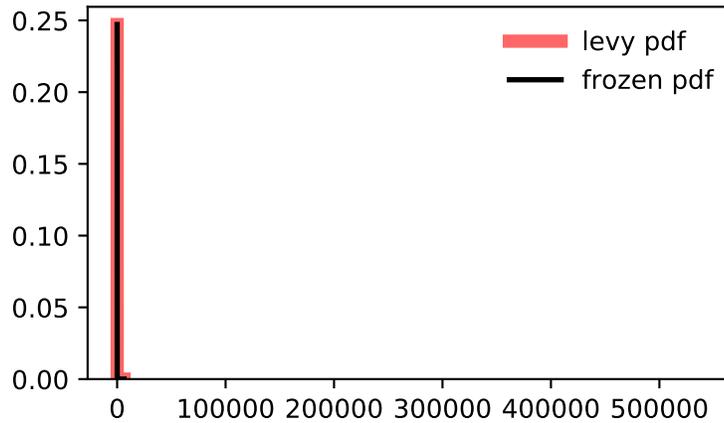

```
>>> vals = levy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.levy_1 = <scipy.stats._continuous_distns.levy_1_gen object>`

A left-skewed Levy continuous random variable.

As an instance of the *rv\_continuous* class, *levy\_1* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**`levy, levy_stable`**Notes**

The probability density function for `levy_l` is:

$$f(x) = \frac{1}{|x|\sqrt{2\pi|x|}} \exp\left(-\frac{1}{2|x|}\right)$$

for  $x < 0$ .

This is the same as the Levy-stable distribution with  $a = 1/2$  and  $b = -1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_l.pdf(x, loc, scale)` is identically equivalent to `levy_l.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import levy_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = levy_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_l.ppf(0.01),
...                 levy_l.ppf(0.99), 100)
>>> ax.plot(x, levy_l.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

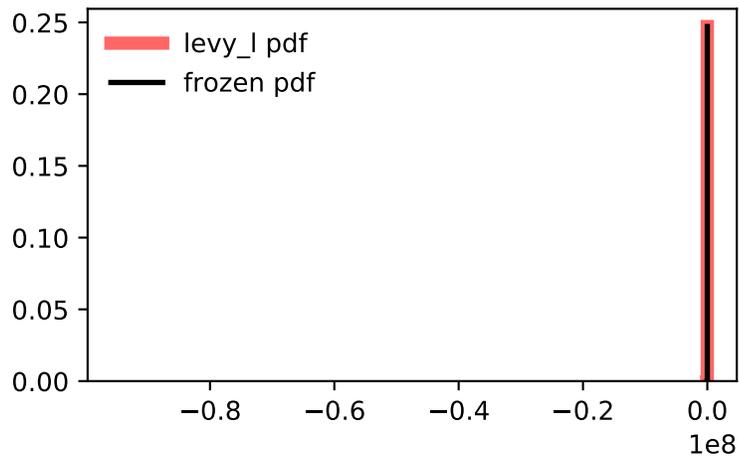

```
>>> vals = levy_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy_l.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy_l.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.levy_stable` = <scipy.stats.continuous\_distns.levy\_stable\_gen object>

A Levy-stable continuous random variable.

As an instance of the *rv\_continuous* class, *levy\_stable* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`levy`, `levy_l`

**Notes**

Levy-stable distribution (only random variates available – ignore other docs)

**Methods**

<code>rvs(alpha, beta, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, alpha, beta, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, alpha, beta, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, alpha, beta, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, alpha, beta, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, alpha, beta, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, alpha, beta, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, alpha, beta, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, alpha, beta, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, alpha, beta, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(alpha, beta, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(alpha, beta, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, alpha, beta, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(alpha, beta), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(alpha, beta, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(alpha, beta, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(alpha, beta, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(alpha, beta, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, alpha, beta, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.logistic = <scipy.stats.continuous_distns.logistic_gen object>`

A logistic (or Sech-squared) continuous random variable.

As an instance of the `rv_continuous` class, `logistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `logistic` is:

$$f(x) = \frac{\exp(-x)}{(1 + \exp(-x))^2}$$

`logistic` is a special case of `genlogistic` with `c == 1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `logistic.pdf(x, loc, scale)` is identically equivalent

to `logistic.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import logistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = logistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(logistic.ppf(0.01),
...                 logistic.ppf(0.99), 100)
>>> ax.plot(x, logistic.pdf(x),
...        'r-', lw=5, alpha=0.6, label='logistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = logistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

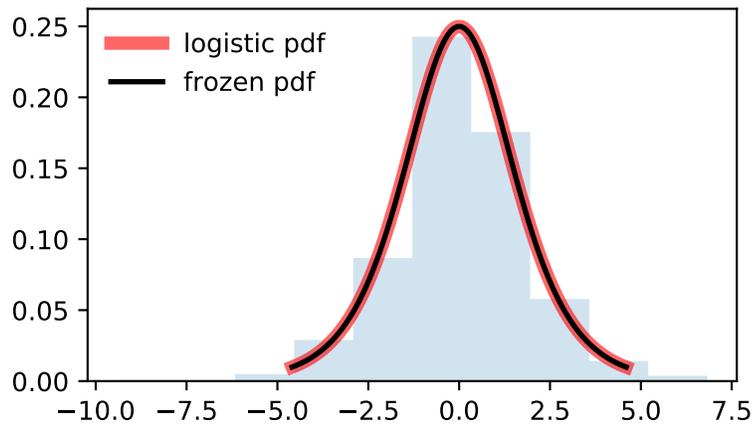

```
>>> vals = logistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], logistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = logistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.loggamma = <scipy.stats.continuous_distns.loggamma_gen object>`

A log gamma continuous random variable.

As an instance of the `rv_continuous` class, `loggamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *loggamma* is:

$$f(x, c) = \frac{\exp(cx - \exp(x))}{\gamma(c)}$$

for all  $x, c > 0$ .

*loggamma* takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loggamma.pdf(x, c, loc, scale)` is identically equivalent to `loggamma.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import loggamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.414
>>> mean, var, skew, kurt = loggamma.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loggamma.ppf(0.01, c),
...                 loggamma.ppf(0.99, c), 100)
>>> ax.plot(x, loggamma.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='loggamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loggamma(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

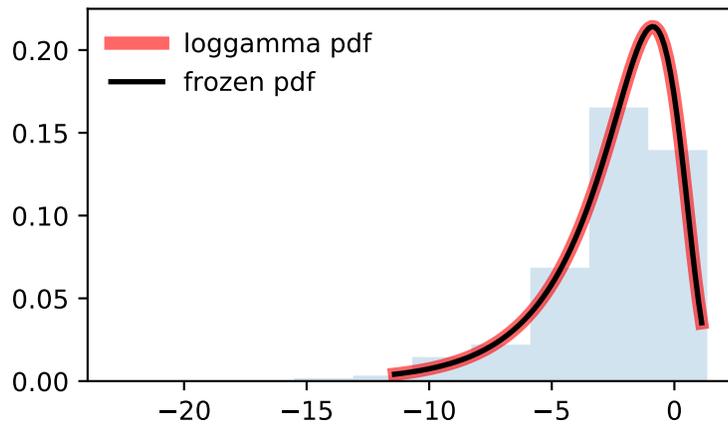

```
>>> vals = loggamma.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loggamma.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loggamma.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.loglaplace = <scipy.stats.continuous_distns.loglaplace_gen object>`

A log-Laplace continuous random variable.

As an instance of the *rv\_continuous* class, *loglaplace* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `loglaplace` is:

$$f(x, c) = \begin{cases} \frac{c}{2}x^{c-1} & \text{for } 0 < x < 1 \\ \frac{c}{2}x^{-c-1} & \text{for } x \geq 1 \end{cases}$$

for  $c > 0$ .

`loglaplace` takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loglaplace.pdf(x, c, loc, scale)` is identically equivalent to `loglaplace.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**References**

T.J. Kozubowski and K. Podgorski, “A log-Laplace growth rate model”, *The Mathematical Scientist*, vol. 28, pp. 49-60, 2003.

**Examples**

```
>>> from scipy.stats import loglaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.25
>>> mean, var, skew, kurt = loglaplace.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loglaplace.ppf(0.01, c),
...                 loglaplace.ppf(0.99, c), 100)
>>> ax.plot(x, loglaplace.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='loglaplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loglaplace(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loglaplace.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loglaplace.cdf(vals, c))
True
```

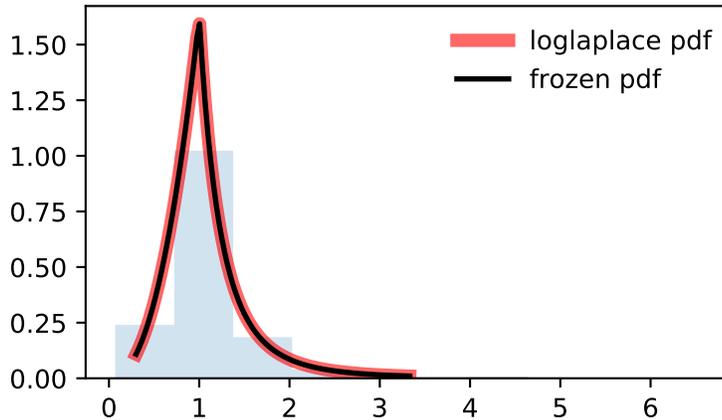

Generate random numbers:

```
>>> r = loglaplace.rvs(c, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
    
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).

<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

`scipy.stats.lognorm` = <scipy.stats.continuous\_distns.lognorm\_gen object>

A lognormal continuous random variable.

As an instance of the `rv_continuous` class, `lognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `lognorm` is:

$$f(x, s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{\log(x)}{s}\right)^2\right)$$

for  $x > 0, s > 0$ .

`lognorm` takes `s` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lognorm.pdf(x, s, loc, scale)` is identically equivalent to `lognorm.pdf(y, s) / scale` with `y = (x - loc) / scale`.

A common parametrization for a lognormal random variable  $Y$  is in terms of the mean, `mu`, and standard deviation, `sigma`, of the unique normally distributed random variable  $X$  such that  $\exp(X) = Y$ . This parametrization corresponds to setting `s = sigma` and `scale = exp(mu)`.

### Examples

```
>>> from scipy.stats import lognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> s = 0.954
>>> mean, var, skew, kurt = lognorm.stats(s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lognorm.ppf(0.01, s),
...                 lognorm.ppf(0.99, s), 100)
>>> ax.plot(x, lognorm.pdf(x, s),
...         'r-', lw=5, alpha=0.6, label='lognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lognorm(s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

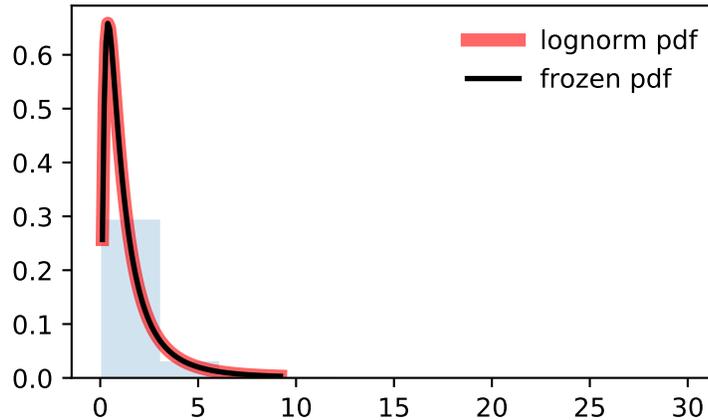

```
>>> vals = lognorm.ppf([0.001, 0.5, 0.999], s)
>>> np.allclose([0.001, 0.5, 0.999], lognorm.cdf(vals, s))
True
```

Generate random numbers:

```
>>> r = lognorm.rvs(s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, s, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, s, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, s, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, s, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, s, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, s, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, s, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, s, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, s, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(s, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(s, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, s, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(s,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(s, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(s, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, s, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.lomax = <scipy.stats._continuous_distns.lomax_gen object>`

A Lomax (Pareto of the second kind) continuous random variable.

As an instance of the `rv_continuous` class, `lomax` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The Lomax distribution is a special case of the Pareto distribution, with (`loc=-1.0`).

The probability density function for `lomax` is:

$$f(x, c) = \frac{c}{(1+x)^{c+1}}$$

for  $x \geq 0, c > 0$ .

`lomax` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lomax.pdf(x, c, loc, scale)` is identically equivalent to `lomax.pdf(y, c) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import lomax
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.88
>>> mean, var, skew, kurt = lomax.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lomax.ppf(0.01, c),
...                 lomax.ppf(0.99, c), 100)
>>> ax.plot(x, lomax.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='lomax pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lomax(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

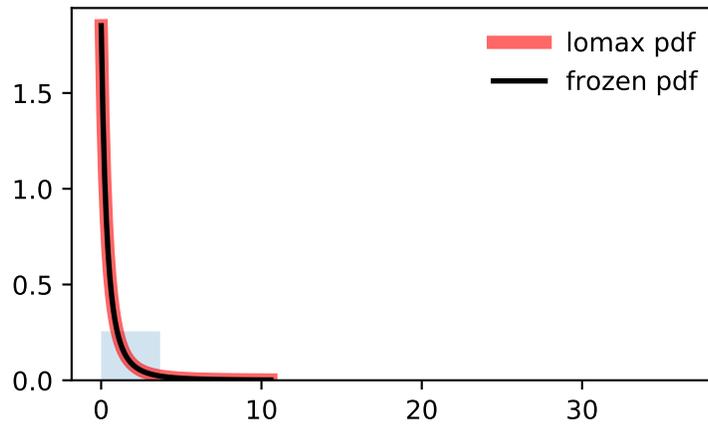

```
>>> vals = lomax.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], lomax.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = lomax.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

`scipy.stats.maxwell = <scipy.stats.continuous_distns.maxwell_gen object>`

A Maxwell continuous random variable.

As an instance of the `rv_continuous` class, `maxwell` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

A special case of a `chi` distribution, with `df = 3`, `loc = 0.0`, and given `scale = a`, where `a` is the parameter used in the Mathworld description [R667].

The probability density function for `maxwell` is:

$$f(x) = \sqrt{2/\pi} x^2 \exp(-x^2/2)$$

for  $x > 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `maxwell.pdf(x, loc, scale)` is identically equivalent to `maxwell.pdf(y) / scale` with `y = (x - loc) / scale`.

### References

[R667]

### Examples

```
>>> from scipy.stats import maxwell
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = maxwell.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(maxwell.ppf(0.01),
...                 maxwell.ppf(0.99), 100)
>>> ax.plot(x, maxwell.pdf(x),
...        'r-', lw=5, alpha=0.6, label='maxwell pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = maxwell()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = maxwell.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], maxwell.cdf(vals))
True
```

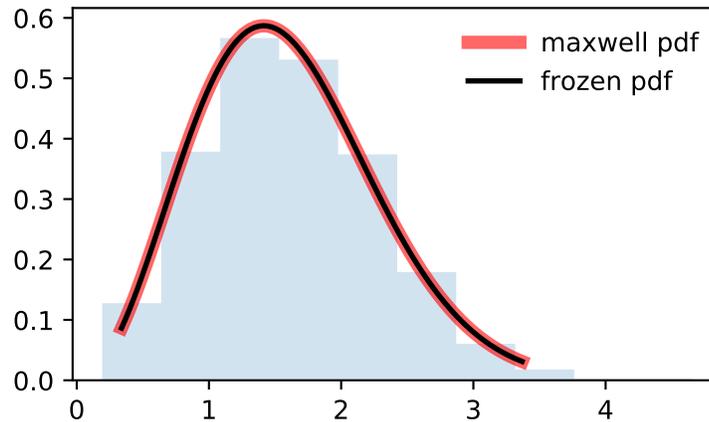

Generate random numbers:

```
>>> r = maxwell.rvs(size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
    
```

`scipy.stats.mielke = <scipy.stats_continuous_distns.mielke_gen object>`

A Mielke’s Beta-Kappa continuous random variable.

As an instance of the `rv_continuous` class, `mielke` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `mielke` is:

$$f(x, k, s) = \frac{kx^{k-1}}{(1+x^s)^{1+k/s}}$$

for  $x > 0$ .

`mielke` takes `k` and `s` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `mielke.pdf(x, k, s, loc, scale)` is identically equivalent to `mielke.pdf(y, k, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import mielke
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> k, s = 10.4, 3.6
>>> mean, var, skew, kurt = mielke.stats(k, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(mielke.ppf(0.01, k, s),
...                 mielke.ppf(0.99, k, s), 100)
>>> ax.plot(x, mielke.pdf(x, k, s),
...         'r-', lw=5, alpha=0.6, label='mielke pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = mielke(k, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

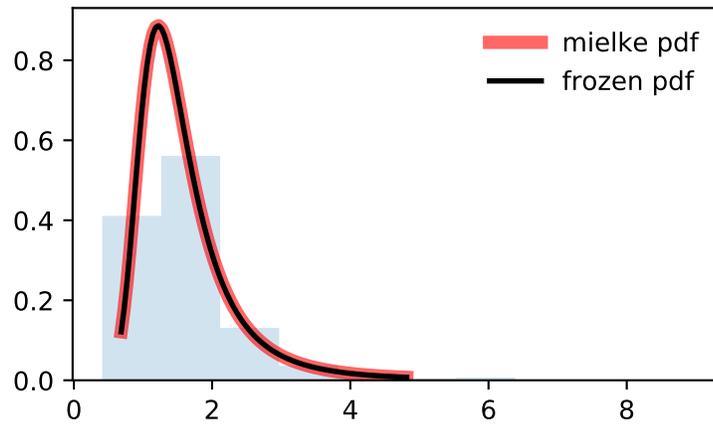

```
>>> vals = mielke.ppf([0.001, 0.5, 0.999], k, s)
>>> np.allclose([0.001, 0.5, 0.999], mielke.cdf(vals, k, s))
True
```

Generate random numbers:

```
>>> r = mielke.rvs(k, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.nakagami` = <scipy.stats.continuous\_distns.nakagami\_gen object>

A Nakagami continuous random variable.

As an instance of the *rv\_continuous* class, *nakagami* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *nakagami* is:

$$f(x, nu) = \frac{2\nu^\nu}{\gamma(\nu)} x^{2\nu-1} \exp(-\nu x^2)$$

for  $x > 0, nu > 0$ .

*nakagami* takes *nu* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `nakagami.pdf(x, nu, loc, scale)` is identically equivalent to `nakagami.pdf(y, nu) / scale` with  $y = (x - loc) / scale$ .

**Examples**

```
>>> from scipy.stats import nakagami
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> nu = 4.97
>>> mean, var, skew, kurt = nakagami.stats(nu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nakagami.ppf(0.01, nu),
...                 nakagami.ppf(0.99, nu), 100)
>>> ax.plot(x, nakagami.pdf(x, nu),
...         'r-', lw=5, alpha=0.6, label='nakagami pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nakagami(nu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

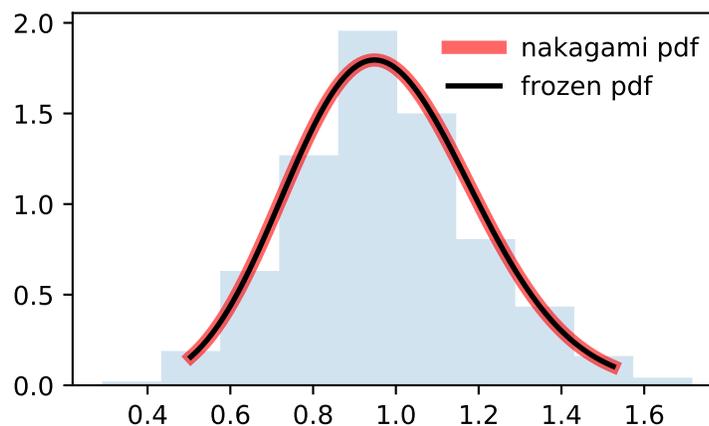

```
>>> vals = nakagami.ppf([0.001, 0.5, 0.999], nu)
>>> np.allclose([0.001, 0.5, 0.999], nakagami.cdf(vals, nu))
True
```

Generate random numbers:

```
>>> r = nakagami.rvs(nu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(nu, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, nu, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, nu, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, nu, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, nu, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, nu, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, nu, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, nu, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, nu, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, nu, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(nu, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(nu, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, nu, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(nu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(nu, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(nu, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(nu, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(nu, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, nu, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.ncx2 = <scipy.stats.continuous_distns.ncx2_gen object>`

A non-central chi-squared continuous random variable.

As an instance of the *rv\_continuous* class, *ncx2* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *ncx2* is:

$$f(x, df, nc) = \exp\left(-\frac{nc + x}{2}\right) \frac{1}{2} (x/nc)^{(df-2)/4} I_{[(df-2)/2]}(\sqrt{ncx})$$

for  $x > 0$ .

*ncx2* takes *df* and *nc* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `ncx2.pdf(x, df, nc, loc, scale)` is identically equivalent to `ncx2.pdf(y, df, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import ncx2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df, nc = 21, 1.06
>>> mean, var, skew, kurt = ncx2.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncx2.ppf(0.01, df, nc),
...                 ncx2.ppf(0.99, df, nc), 100)
>>> ax.plot(x, ncx2.pdf(x, df, nc),
...         'r-', lw=5, alpha=0.6, label='ncx2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncx2(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

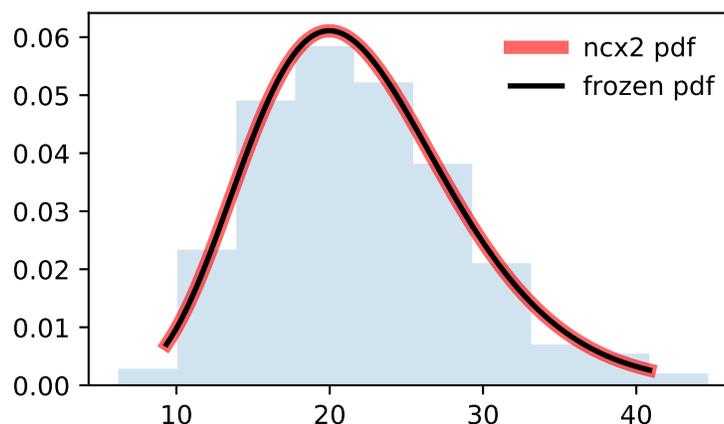

```
>>> vals = ncx2.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncx2.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = ncx2.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(df, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, nc, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, df, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, df, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, df, nc, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(df, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, nc, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.ncf` = <scipy.stats.continuous\_distns.ncf\_gen object>

A non-central F distribution continuous random variable.

As an instance of the `rv_continuous` class, `ncf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `ncf` is:

$$f(x, n_1, n_2, \lambda) = \exp\left(\frac{\lambda}{2} + \lambda n_1 \frac{x}{2(n_1 x + n_2)}\right) n_1^{n_1/2} n_2^{n_2/2} x^{n_1/2-1} \\ (n_2 + n_1 x)^{-(n_1+n_2)/2} \gamma(n_1/2) \gamma(1 + n_2/2) \\ \frac{L_{\frac{v_1}{2}-1}(-\lambda v_1 \frac{x}{2(v_1 x + v_2)})}{(B(v_1/2, v_2/2) \gamma(\frac{v_1+v_2}{2}))}$$

for  $n_1 > 1$ ,  $n_2, \lambda > 0$ . Here  $n_1$  is the degrees of freedom in the numerator,  $n_2$  the degrees of freedom in the denominator,  $\lambda$  the non-centrality parameter,  $\gamma$  is the logarithm of the Gamma function,  $L_n^k$  is a generalized Laguerre polynomial and  $B$  is the beta function.

`ncf` takes `df1`, `df2` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncf.pdf(x, dfn, dfd, nc, loc, scale)` is identically

equivalent to `ncf.pdf(y, dfn, dfd, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import ncf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> dfn, dfd, nc = 27, 27, 0.416
>>> mean, var, skew, kurt = ncf.stats(dfn, dfd, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncf.ppf(0.01, dfn, dfd, nc),
...                 ncf.ppf(0.99, dfn, dfd, nc), 100)
>>> ax.plot(x, ncf.pdf(x, dfn, dfd, nc),
...         'r-', lw=5, alpha=0.6, label='ncf pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncf(dfn, dfd, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

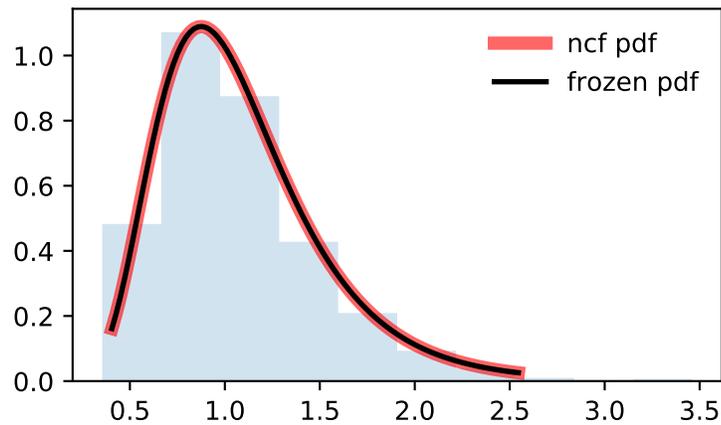

```
>>> vals = ncf.ppf([0.001, 0.5, 0.999], dfn, dfd, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncf.cdf(vals, dfn, dfd, nc))
True
```

Generate random numbers:

```
>>> r = ncf.rvs(dfn, dfd, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(dfn, dfd, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, dfn, dfd, nc, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, dfn, dfd, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, dfn, dfd, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(dfn, dfd, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(dfn, dfd, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, dfn, dfd, nc, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(dfn, dfd, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(dfn, dfd, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(dfn, dfd, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(dfn, dfd, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(dfn, dfd, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, dfn, dfd, nc, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.nct` = <`scipy.stats.continuous_distns.nct_gen` object>

A non-central Student's T continuous random variable.

As an instance of the `rv_continuous` class, `nct` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `nct` is:

$$f(x, df, nc) = \frac{df^{df/2} \gamma(df + 1)}{2^{df} \exp(nc^2/2) (df + x^2)^{df/2} \gamma(df/2)}$$

for  $df > 0$ .

`nct` takes `df` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nct.pdf(x, df, nc, loc, scale)` is identically equivalent to `nct.pdf(y, df, nc) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import nct
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df, nc = 14, 0.24
>>> mean, var, skew, kurt = nct.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nct.ppf(0.01, df, nc),
...                 nct.ppf(0.99, df, nc), 100)
>>> ax.plot(x, nct.pdf(x, df, nc),
...         'r-', lw=5, alpha=0.6, label='nct pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nct(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

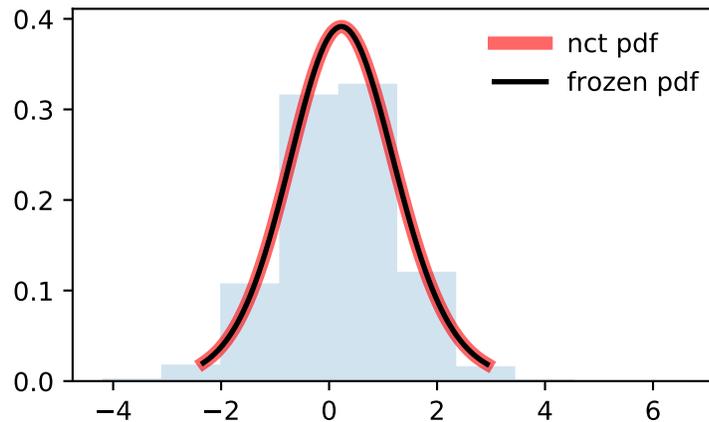

```
>>> vals = nct.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], nct.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = nct.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(df, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, nc, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, df, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, df, nc, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(df, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, nc, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.norm = <scipy.stats.continuous_distns.norm_gen object>`

A normal continuous random variable.

The location (*loc*) keyword specifies the mean. The scale (*scale*) keyword specifies the standard deviation.

As an instance of the `rv_continuous` class, `norm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `norm` is:

$$f(x) = \frac{\exp(-x^2/2)}{\sqrt{2\pi}}$$

The survival function, `norm.sf`, is also referred to as the Q-function in some contexts (see, e.g., [Wikipedia's definition](#)).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norm.pdf(x, loc, scale)` is identically equivalent to `norm.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = norm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norm.ppf(0.01),
...                 norm.ppf(0.99), 100)
>>> ax.plot(x, norm.pdf(x),
...         'r-', lw=5, alpha=0.6, label='norm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

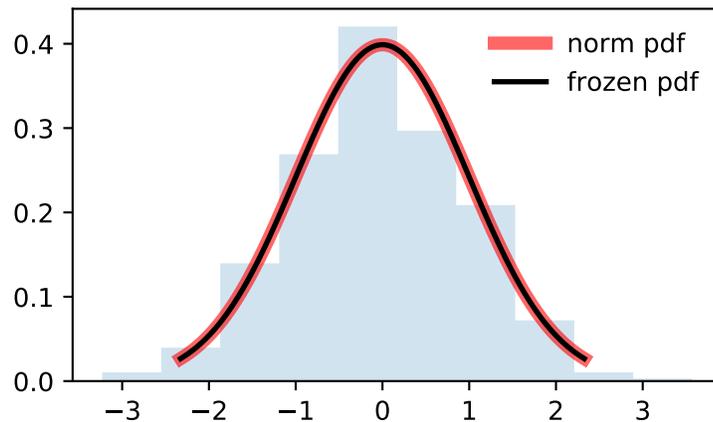

```
>>> vals = norm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], norm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = norm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.pareto` = <scipy.stats.continuous\_distns.pareto\_gen object>

A Pareto continuous random variable.

As an instance of the *rv\_continuous* class, *pareto* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *pareto* is:

$$f(x, b) = \frac{b}{x^{b+1}}$$

for  $x \geq 1, b > 0$ .

*pareto* takes *b* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `pareto.pdf(x, b, loc, scale)` is identically equivalent to `pareto.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import pareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 2.62
>>> mean, var, skew, kurt = pareto.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pareto.ppf(0.01, b),
...                 pareto.ppf(0.99, b), 100)
>>> ax.plot(x, pareto.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='pareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pareto(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

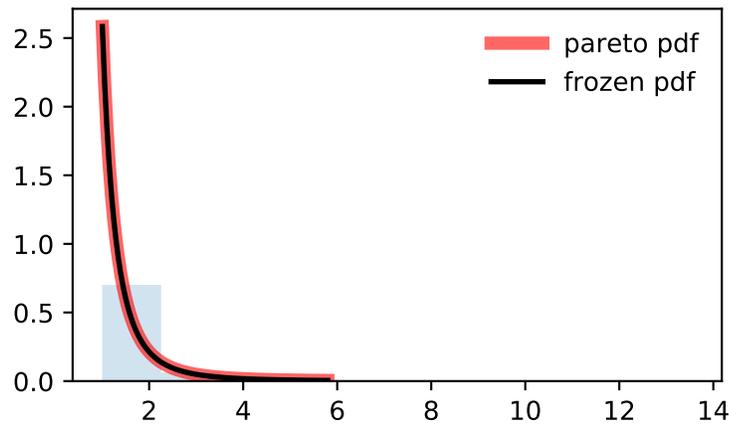

```
>>> vals = pareto.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], pareto.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = pareto.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.pearson3 = <scipy.stats.continuous_distns.pearson3_gen object>`

A pearson type III continuous random variable.

As an instance of the `rv_continuous` class, `pearson3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `pearson3` is:

$$f(x, skew) = \frac{|\beta|}{\gamma(\alpha)} (\beta(x - \zeta))^{\alpha-1} \exp(-\beta(x - \zeta))$$

where:

$$\beta = \frac{2}{skewstddev} \alpha = (stddev\beta)^2 \zeta = loc - \frac{\alpha}{\beta}$$

`pearson3` takes `skew` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pearson3.pdf(x, skew, loc, scale)` is identically equivalent to `pearson3.pdf(y, skew) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import pearson3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> skew = 0.1
>>> mean, var, skew, kurt = pearson3.stats(skew, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pearson3.ppf(0.01, skew),
...                 pearson3.ppf(0.99, skew), 100)
>>> ax.plot(x, pearson3.pdf(x, skew),
...         'r-', lw=5, alpha=0.6, label='pearson3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pearson3(skew)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

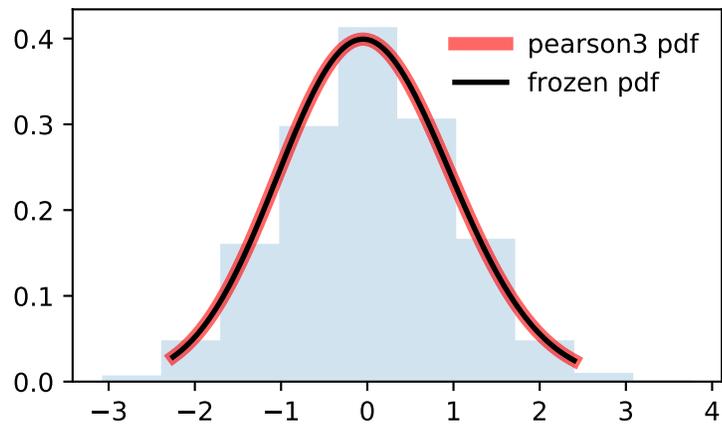

```
>>> vals = pearson3.ppf([0.001, 0.5, 0.999], skew)
>>> np.allclose([0.001, 0.5, 0.999], pearson3.cdf(vals, skew))
True
```

Generate random numbers:

```
>>> r = pearson3.rvs(skew, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.powerlaw = <scipy.stats.continuous_distns.powerlaw_gen object>`

A power-function continuous random variable.

As an instance of the *rv\_continuous* class, *powerlaw* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *powerlaw* is:

$$f(x, a) = ax^{a-1}$$

for  $0 \leq x \leq 1, a > 0$ .

*powerlaw* takes *a* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `powerlaw.pdf(x, a, loc, scale)` is identically equivalent to `powerlaw.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

*powerlaw* is a special case of *beta* with  $b == 1$ .

**Examples**

```
>>> from scipy.stats import powerlaw
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.66
>>> mean, var, skew, kurt = powerlaw.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlaw.ppf(0.01, a),
...                 powerlaw.ppf(0.99, a), 100)
>>> ax.plot(x, powerlaw.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='powerlaw pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlaw(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

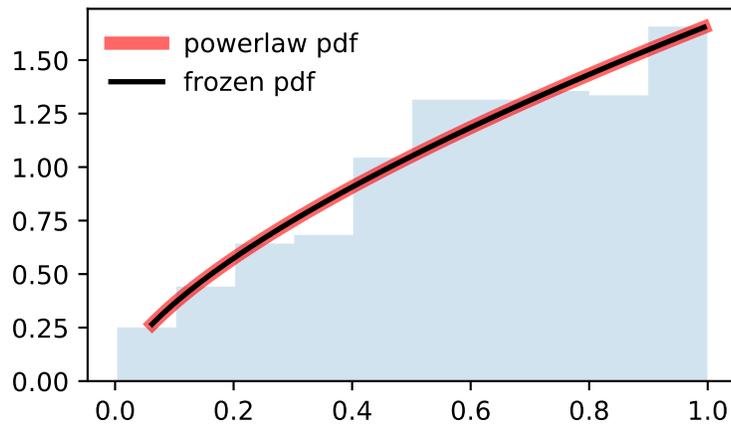

```
>>> vals = powerlaw.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], powerlaw.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = powerlaw.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).

<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.powerlognorm = <scipy.stats._continuous_distns.powerlognorm_gen object>`

A power log-normal continuous random variable.

As an instance of the `rv_continuous` class, `powerlognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `powerlognorm` is:

$$f(x, c, s) = \frac{c}{xs} \phi(\log(x)/s) (\Phi(-\log(x)/s))^{c-1}$$

where  $\phi$  is the normal pdf, and  $\Phi$  is the normal cdf, and  $x > 0, s, c > 0$ .

`powerlognorm` takes  $c$  and  $s$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powerlognorm.pdf(x, c, s, loc, scale)` is identically equivalent to `powerlognorm.pdf(y, c, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import powerlognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, s = 2.14, 0.446
>>> mean, var, skew, kurt = powerlognorm.stats(c, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlognorm.ppf(0.01, c, s),
...                 powerlognorm.ppf(0.99, c, s), 100)
>>> ax.plot(x, powerlognorm.pdf(x, c, s),
...         'r-', lw=5, alpha=0.6, label='powerlognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlognorm(c, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

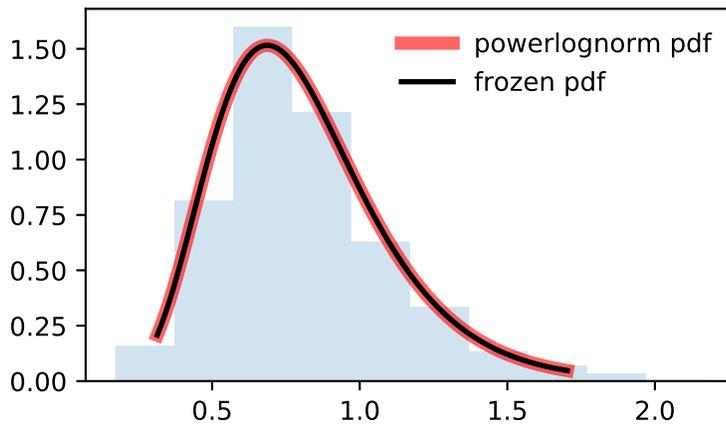

```
>>> vals = powerlognorm.ppf([0.001, 0.5, 0.999], c, s)
>>> np.allclose([0.001, 0.5, 0.999], powerlognorm.cdf(vals, c, s))
True
```

Generate random numbers:

```
>>> r = powerlognorm.rvs(c, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, s, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, s, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, s, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, s, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, s, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, s, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, s, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, s, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, s, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, s, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, s, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, s, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c, s), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, s, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, s, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, s, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.powernorm = <scipy.stats.continuous_distns.powernorm_gen object>`

A power normal continuous random variable.

As an instance of the *rv\_continuous* class, *powernorm* object inherits from it a collection of generic

methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *powernorm* is:

$$f(x, c) = c\phi(x)(\Phi(-x))^{c-1}$$

where  $\phi$  is the normal pdf, and  $\Phi$  is the normal cdf, and  $x > 0, c > 0$ .

*powernorm* takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `powernorm.pdf(x, c, loc, scale)` is identically equivalent to `powernorm.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import powernorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 4.45
>>> mean, var, skew, kurt = powernorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powernorm.ppf(0.01, c),
...                 powernorm.ppf(0.99, c), 100)
>>> ax.plot(x, powernorm.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='powernorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powernorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

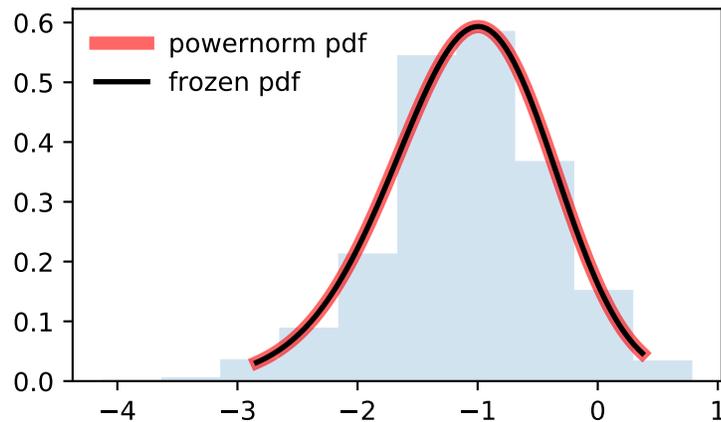

```
>>> vals = powernorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], powernorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = powernorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.rdist = <scipy.stats.continuous_distns.rdist_gen object>`

An R-distributed continuous random variable.

As an instance of the `rv_continuous` class, `rdist` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *rdist* is:

$$f(x, c) = \frac{(1 - x^2)^{c/2-1}}{B(1/2, c/2)}$$

for  $-1 \leq x \leq 1, c > 0$ .

*rdist* takes *c* as a shape parameter.

This distribution includes the following distribution kernels as special cases:

```
c = 2: uniform
c = 4: Epanechnikov (parabolic)
c = 6: quartic (biweight)
c = 8: triweight
```

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `rdist.pdf(x, c, loc, scale)` is identically equivalent to `rdist.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import rdist
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.9
>>> mean, var, skew, kurt = rdist.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rdist.ppf(0.01, c),
...                 rdist.ppf(0.99, c), 100)
>>> ax.plot(x, rdist.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='rdist pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rdist(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

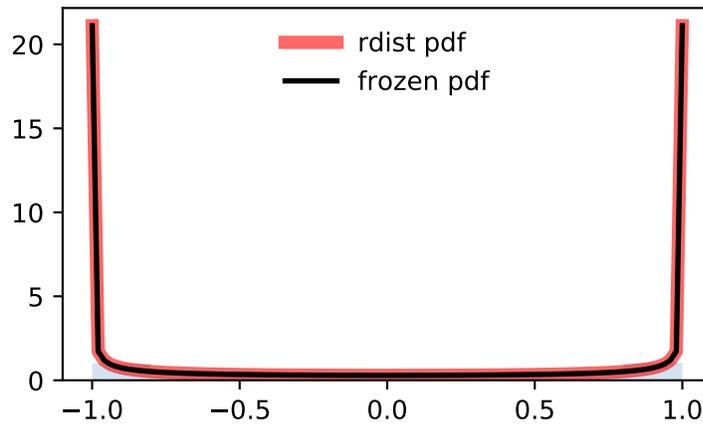

```
>>> vals = rdist.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], rdist.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = rdist.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

`scipy.stats.reciprocal` = <scipy.stats\_continuous\_distns.reciprocal\_gen object>

A reciprocal continuous random variable.

As an instance of the *rv\_continuous* class, *reciprocal* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *reciprocal* is:

$$f(x, a, b) = \frac{1}{x \log(b/a)}$$

for  $a \leq x \leq b, a, b > 0$ .

*reciprocal* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `reciprocal.pdf(x, a, b, loc, scale)` is identically equivalent to `reciprocal.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import reciprocal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 0.00623, 1.01
>>> mean, var, skew, kurt = reciprocal.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(reciprocal.ppf(0.01, a, b),
...                 reciprocal.ppf(0.99, a, b), 100)
>>> ax.plot(x, reciprocal.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='reciprocal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = reciprocal(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

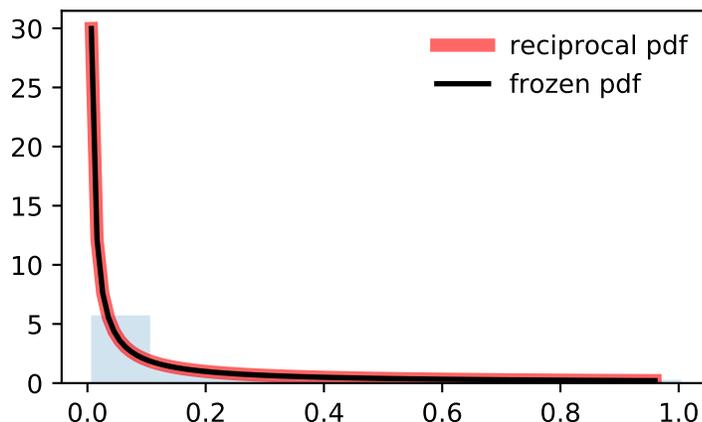

```
>>> vals = reciprocal.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], reciprocal.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = reciprocal.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.rayleigh = <scipy.stats.continuous_distns.rayleigh_gen object>`

A Rayleigh continuous random variable.

As an instance of the *rv\_continuous* class, *rayleigh* object inherits from it a collection of generic meth-

ods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `rayleigh` is:

$$f(r) = r \exp(-r^2/2)$$

for  $x \geq 0$ .

`rayleigh` is a special case of `chi` with `df == 2`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rayleigh.pdf(x, loc, scale)` is identically equivalent to `rayleigh.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import rayleigh
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = rayleigh.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rayleigh.ppf(0.01),
...                 rayleigh.ppf(0.99), 100)
>>> ax.plot(x, rayleigh.pdf(x),
...         'r-', lw=5, alpha=0.6, label='rayleigh pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rayleigh()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

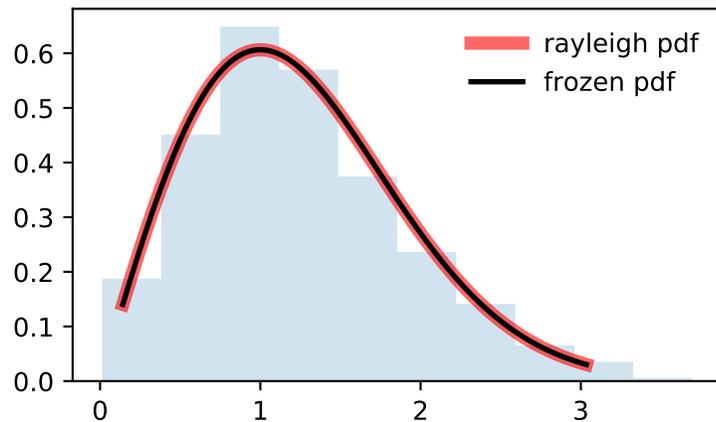

```
>>> vals = rayleigh.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], rayleigh.cdf(vals))
True
```

Generate random numbers:

```
>>> r = rayleigh.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.rice = <scipy.stats_continuous_distns.rice_gen object>`

A Rice continuous random variable.

As an instance of the `rv_continuous` class, *rice* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *rice* is:

$$f(x, b) = x \exp\left(-\frac{x^2 + b^2}{2}\right) I_0(xb)$$

for  $x > 0, b > 0$ .

*rice* takes *b* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `rice.pdf(x, b, loc, scale)` is identically equivalent to `rice.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

The Rice distribution describes the length, *r*, of a 2-D vector with components  $(U + u, V + v)$ , where *U, V* are constant, *u, v* are independent Gaussian random variables with standard deviation *s*. Let  $R = \sqrt{U^2 + V^2}$ . Then the pdf of *r* is `rice.pdf(x, R/s, scale=s)`.

### Examples

```
>>> from scipy.stats import rice
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 0.775
>>> mean, var, skew, kurt = rice.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rice.ppf(0.01, b),
...                 rice.ppf(0.99, b), 100)
>>> ax.plot(x, rice.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='rice pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rice(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

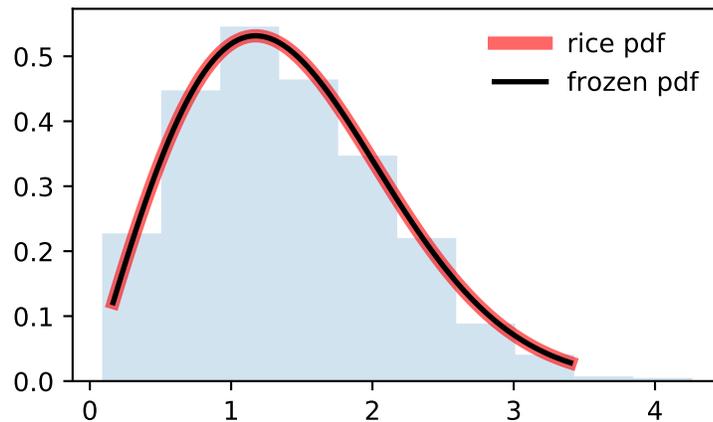

```
>>> vals = rice.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], rice.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = rice.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.recipinvgauss = <scipy.stats.continuous_distns.recipinvgauss_gen object>`

A reciprocal inverse Gaussian continuous random variable.

As an instance of the *rv\_continuous* class, *recipinvgauss* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *recipinvgauss* is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x}} \frac{\exp(-(1 - \mu x)^2)}{2x\mu^2}$$

for  $x \geq 0$ .

*recipinvgauss* takes  $\mu$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `recipinvgauss.pdf(x, mu, loc, scale)` is identically equivalent to `recipinvgauss.pdf(y, mu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import recipinvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.63
>>> mean, var, skew, kurt = recipinvgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(recipinvgauss.ppf(0.01, mu),
...                 recipinvgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, recipinvgauss.pdf(x, mu),
...         'r-', lw=5, alpha=0.6, label='recipinvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = recipinvgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

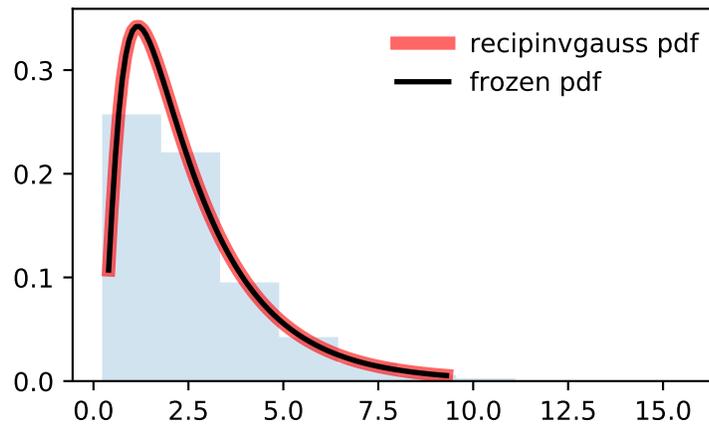

```
>>> vals = recipinvgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], recipinvgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = recipinvgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(mu, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, mu, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, mu, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, mu, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, mu, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, mu, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, mu, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, mu, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, mu, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, mu, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(mu, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(mu, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, mu, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(mu, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(mu, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(mu, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(mu, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, mu, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.semicircular = <scipy.stats._continuous_distns.semicircular_gen object>`

A semicircular continuous random variable.

As an instance of the `rv_continuous` class, `semicircular` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *semicircular* is:

$$f(x) = \frac{2}{\pi} \sqrt{1 - x^2}$$

for  $-1 \leq x \leq 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `semicircular.pdf(x, loc, scale)` is identically equivalent to `semicircular.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import semicircular
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = semicircular.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(semicircular.ppf(0.01),
...                 semicircular.ppf(0.99), 100)
>>> ax.plot(x, semicircular.pdf(x),
...         'r-', lw=5, alpha=0.6, label='semicircular pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = semicircular()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

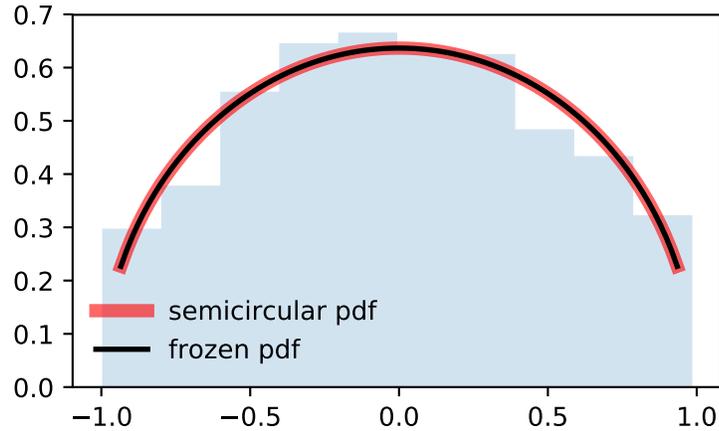

```
>>> vals = semicircular.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], semicircular.cdf(vals))
True
```

Generate random numbers:

```
>>> r = semicircular.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.skewnorm` = <scipy.stats.continuous\_distns.skew\_norm\_gen object>

A skew-normal random variable.

As an instance of the `rv_continuous` class, `skewnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The pdf is:

```
skewnorm.pdf(x, a) = 2 * norm.pdf(x) * norm.cdf(a*x)
```

*skewnorm* takes *a* as a skewness parameter. When *a* = 0 the distribution is identical to a normal distribution. *rvs* implements the method of [R697].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `skewnorm.pdf(x, a, loc, scale)` is identically equivalent to `skewnorm.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### References

[R697]

### Examples

```
>>> from scipy.stats import skewnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 4
>>> mean, var, skew, kurt = skewnorm.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(skewnorm.ppf(0.01, a),
...                 skewnorm.ppf(0.99, a), 100)
>>> ax.plot(x, skewnorm.pdf(x, a),
...        'r-', lw=5, alpha=0.6, label='skewnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = skewnorm(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

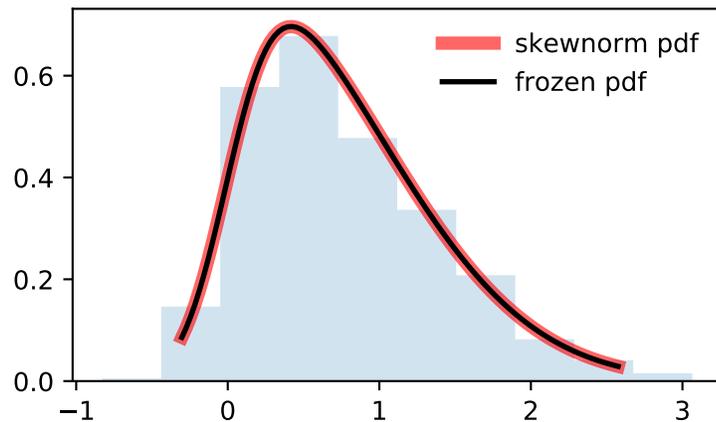

```
>>> vals = skewnorm.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewnorm.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = skewnorm.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.

<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.t` = <scipy.stats.continuous\_distns.t\_gen object>

A Student's T continuous random variable.

As an instance of the *rv\_continuous* class, *t* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for  $t$  is:

$$f(x, df) = \frac{\gamma((df + 1)/2)}{\sqrt{\pi * df} \gamma(df/2) (1 + x^2/df)^{(df+1)/2}}$$

for  $df > 0$ .

$t$  takes  $df$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `t.pdf(x, df, loc, scale)` is identically equivalent to `t.pdf(y, df) / scale` with  $y = (x - loc) / scale$ .

**Examples**

```
>>> from scipy.stats import t
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 2.74
>>> mean, var, skew, kurt = t.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(t.ppf(0.01, df),
...                 t.ppf(0.99, df), 100)
>>> ax.plot(x, t.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='t pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = t(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

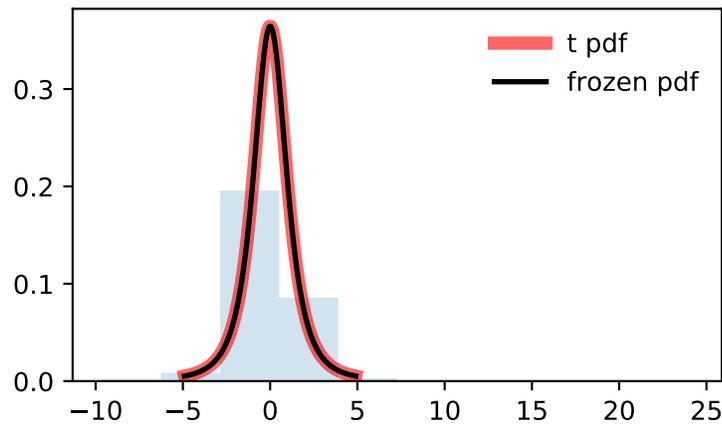

```
>>> vals = t.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], t.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = t.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(df, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).

<code>mean(df, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.trapz = <scipy.stats.continuous_distns.trapz_gen object>`

A trapezoidal continuous random variable.

As an instance of the *rv\_continuous* class, *trapz* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The trapezoidal distribution can be represented with an up-sloping line from `loc` to `(loc + c*scale)`, then constant to `(loc + d*scale)` and then downsloping from `(loc + d*scale)` to `(loc+scale)`.

`trapz` takes `c` and `d` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `trapz.pdf(x, c, d, loc, scale)` is identically equivalent to `trapz.pdf(y, c, d) / scale` with `y = (x - loc) / scale`.

The standard form is in the range `[0, 1]` with `c` the mode. The location parameter shifts the start to `loc`. The scale parameter changes the width from 1 to `scale`.

**Examples**

```
>>> from scipy.stats import trapz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 0.2, 0.8
>>> mean, var, skew, kurt = trapz.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(trapz.ppf(0.01, c, d),
...                 trapz.ppf(0.99, c, d), 100)
>>> ax.plot(x, trapz.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='trapz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = trapz(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

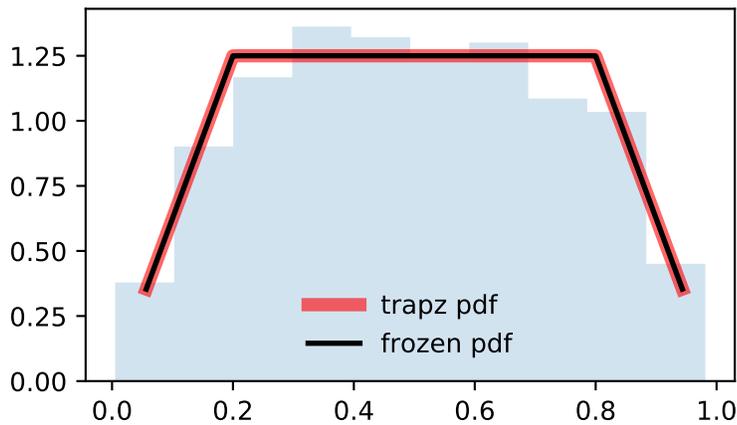

```
>>> vals = trapz.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], trapz.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = trapz.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, d, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, d, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, d, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, d, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, d, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, d, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, d, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, d, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, d, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, d, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, d, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, d, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, d, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c, d), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, d, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, d, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, d, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, d, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, d, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.triang = <scipy.stats.continuous_distns.triang_gen object>`

A triangular continuous random variable.

As an instance of the *rv\_continuous* class, *triang* object inherits from it a collection of generic methods

(see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The triangular distribution can be represented with an up-sloping line from `loc` to `(loc + c*scale)` and then downsloping for `(loc + c*scale)` to `(loc+scale)`.

`triang` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `triang.pdf(x, c, loc, scale)` is identically equivalent to `triang.pdf(y, c) / scale` with `y = (x - loc) / scale`.

The standard form is in the range `[0, 1]` with `c` the mode. The location parameter shifts the start to `loc`. The scale parameter changes the width from 1 to `scale`.

### Examples

```
>>> from scipy.stats import triang
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.158
>>> mean, var, skew, kurt = triang.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(triang.ppf(0.01, c),
...                 triang.ppf(0.99, c), 100)
>>> ax.plot(x, triang.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='triang pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = triang(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

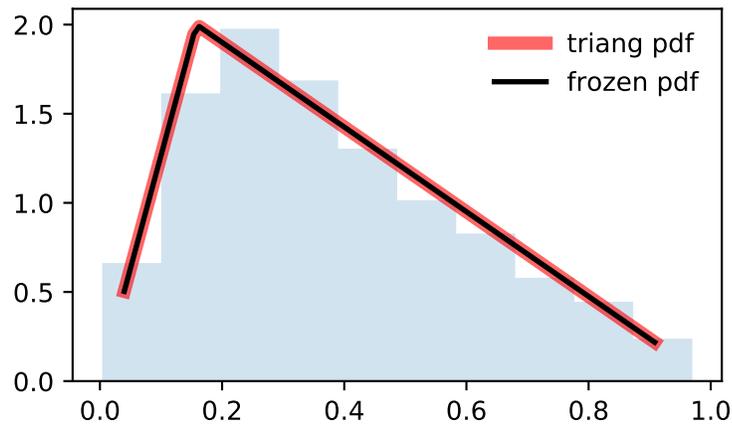

```
>>> vals = triang.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], triang.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = triang.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.truncexpon = <scipy.stats.continuous_distns.truncexpon_gen object>`

A truncated exponential continuous random variable.

As an instance of the *rv\_continuous* class, *truncexpon* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *truncexpon* is:

$$f(x, b) = \frac{\exp(-x)}{1 - \exp(-b)}$$

for  $0 < x < b$ .

*truncexpon* takes *b* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `truncexpon.pdf(x, b, loc, scale)` is identically equivalent to `truncexpon.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import truncexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 4.69
>>> mean, var, skew, kurt = truncexpon.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncexpon.ppf(0.01, b),
...                 truncexpon.ppf(0.99, b), 100)
>>> ax.plot(x, truncexpon.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='truncexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncexpon(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

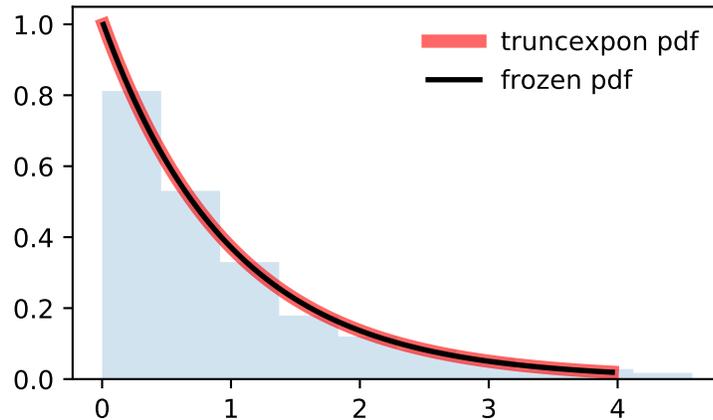

```
>>> vals = truncexpon.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], truncexpon.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = truncexpon.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.truncnorm` = <scipy.stats.continuous\_distns.truncnorm\_gen object>

A truncated normal continuous random variable.

As an instance of the *rv\_continuous* class, *truncnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The standard form of this distribution is a standard normal truncated to the range  $[a, b]$  — notice that  $a$  and  $b$  are defined over the domain of the standard normal. To convert clip values for a specific mean and standard deviation, use:

```
a, b = (myclip_a - my_mean) / my_std, (myclip_b - my_mean) / my_std
```

`truncnorm` takes  $a$  and  $b$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncnorm.pdf(x, a, b, loc, scale)` is identically equivalent to `truncnorm.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import truncnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 0.1, 2
>>> mean, var, skew, kurt = truncnorm.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncnorm.ppf(0.01, a, b),
...                 truncnorm.ppf(0.99, a, b), 100)
>>> ax.plot(x, truncnorm.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='truncnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncnorm(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

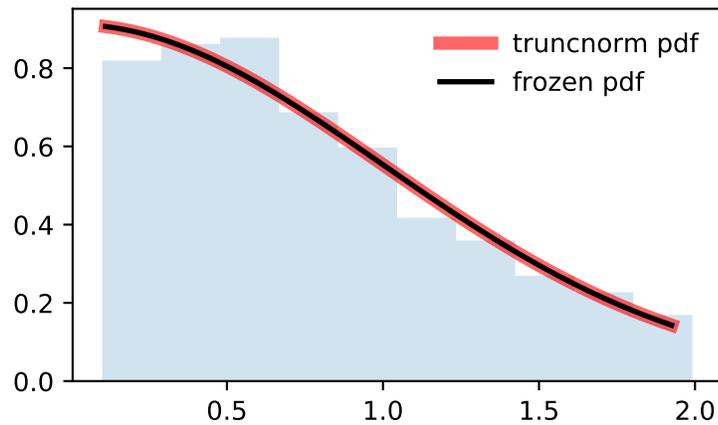

```
>>> vals = truncnorm.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], truncnorm.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = truncnorm.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.tukeylambda = <scipy.stats.continuous_distns.tukeylambda_gen object>`

A Tukey-Lambda continuous random variable.

As an instance of the *rv\_continuous* class, *tukeylambda* object inherits from it a collection of generic

methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

A flexible distribution, able to represent and interpolate between the following distributions:

- Cauchy (lam=-1)
- logistic (lam=0.0)
- approx Normal (lam=0.14)
- u-shape (lam = 0.5)
- uniform from -1 to 1 (lam = 1)

`tukeylambda` takes `lam` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `tukeylambda.pdf(x, lam, loc, scale)` is identically equivalent to `tukeylambda.pdf(y, lam) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import tukeylambda
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lam = 3.13
>>> mean, var, skew, kurt = tukeylambda.stats(lam, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(tukeylambda.ppf(0.01, lam),
...                 tukeylambda.ppf(0.99, lam), 100)
>>> ax.plot(x, tukeylambda.pdf(x, lam),
...         'r-', lw=5, alpha=0.6, label='tukeylambda pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = tukeylambda(lam)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

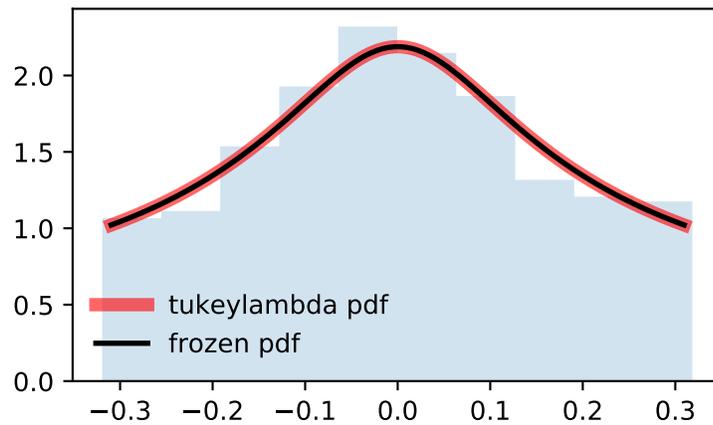

```
>>> vals = tukeylambda.ppf([0.001, 0.5, 0.999], lam)
>>> np.allclose([0.001, 0.5, 0.999], tukeylambda.cdf(vals, lam))
True
```

Generate random numbers:

```
>>> r = tukeylambda.rvs(lam, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(lam, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, lam, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, lam, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, lam, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, lam, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, lam, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, lam, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, lam, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, lam, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, lam, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(lam, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(lam, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, lam, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(lam,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(lam, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(lam, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(lam, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(lam, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, lam, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.uniform` = <scipy.stats.continuous\_distns.uniform\_gen object>

A uniform continuous random variable.

This distribution is constant between *loc* and *loc* + *scale*.

As an instance of the `rv_continuous` class, `uniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```
>>> from scipy.stats import uniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = uniform.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(uniform.ppf(0.01),
...                 uniform.ppf(0.99), 100)
>>> ax.plot(x, uniform.pdf(x),
...        'r-', lw=5, alpha=0.6, label='uniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = uniform()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

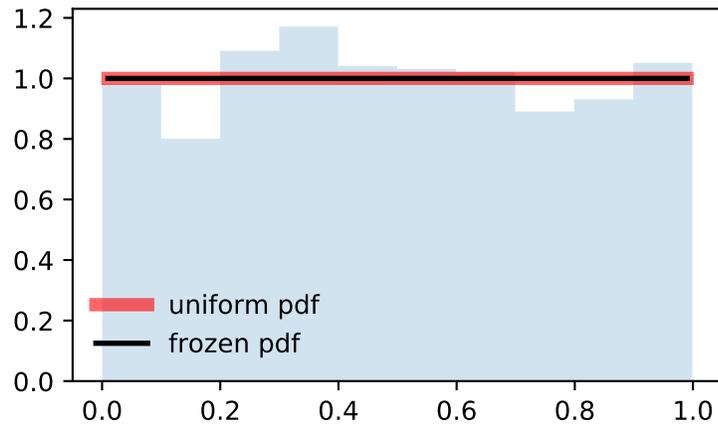

```
>>> vals = uniform.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], uniform.cdf(vals))
True
```

Generate random numbers:

```
>>> r = uniform.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.vonmises = <scipy.stats.continuous_distns.vonmises_gen object>`

A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

### `vonmises_line`

The same distribution, defined on a  $[-\pi, \pi]$  segment of the real line.

### Notes

If  $x$  is not in range or  $loc$  is not in range it assumes they are angles and converts them to  $[-\pi, \pi]$  equivalents.

The probability density function for `vonmises` is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for  $-\pi \leq x \leq \pi, \kappa > 0$ .

`vonmises` takes  $\kappa$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises.pdf(y, kappa) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import vonmises
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises.ppf(0.01, kappa),
...                 vonmises.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='vonmises pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

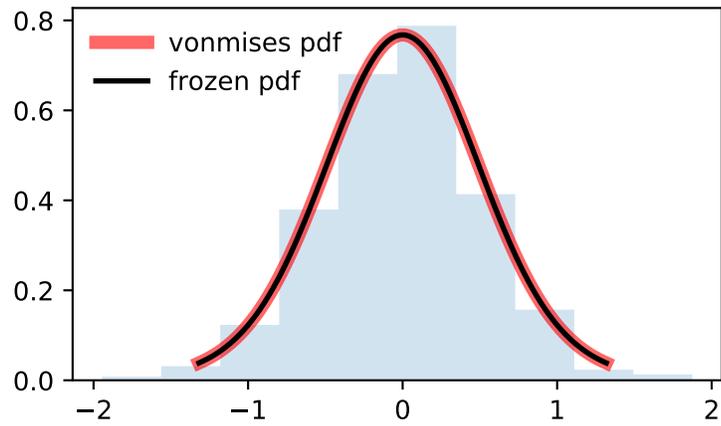

```
>>> vals = vonmises.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

<code>rvs(kappa, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, kappa, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, kappa, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, kappa, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, kappa, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, kappa, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, kappa, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, kappa, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, kappa, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, kappa, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(kappa, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(kappa, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, kappa, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(kappa,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(kappa, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(kappa, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(kappa, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(kappa, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, kappa, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.vonmises_line = <scipy.stats.continuous_distns.vonmises_gen object>`

A Von Mises continuous random variable.

As an instance of the *rv\_continuous* class, *vonmises\_line* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:****vonmises\_line**

The same distribution, defined on a  $[-\pi, \pi]$  segment of the real line.

**Notes**

If *x* is not in range or *loc* is not in range it assumes they are angles and converts them to  $[-\pi, \pi]$  equivalents.

The probability density function for *vonmises* is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for  $-\pi \leq x \leq \pi, \kappa > 0$ .

*vonmises* takes  $\kappa$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `vonmises_line.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises_line.pdf(y, kappa) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import vonmises_line
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises_line.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises_line.ppf(0.01, kappa),
...                 vonmises_line.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises_line.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='vonmises_line pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises_line(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

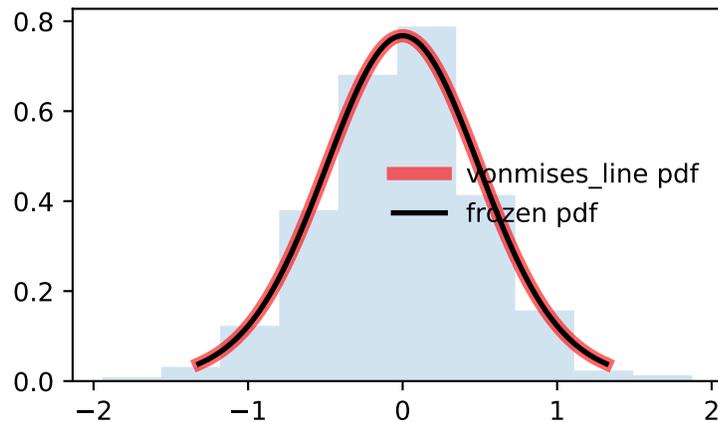

```
>>> vals = vonmises_line.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises_line.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises_line.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(kappa, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, kappa, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, kappa, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, kappa, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, kappa, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, kappa, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, kappa, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, kappa, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, kappa, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, kappa, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(kappa, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(kappa, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, kappa, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(kappa,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(kappa, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(kappa, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(kappa, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(kappa, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, kappa, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.wald = <scipy.stats_continuous_distns.wald_gen object>`

A Wald continuous random variable.

As an instance of the *rv\_continuous* class, *wald* object inherits from it a collection of generic methods

(see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *wald* is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x-1)^2}{2x}\right)$$

for  $x > 0$ .

*wald* is a special case of *invgauss* with `mu == 1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wald.pdf(x, loc, scale)` is identically equivalent to `wald.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import wald
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = wald.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wald.ppf(0.01),
...                 wald.ppf(0.99), 100)
>>> ax.plot(x, wald.pdf(x),
...         'r-', lw=5, alpha=0.6, label='wald pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wald()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

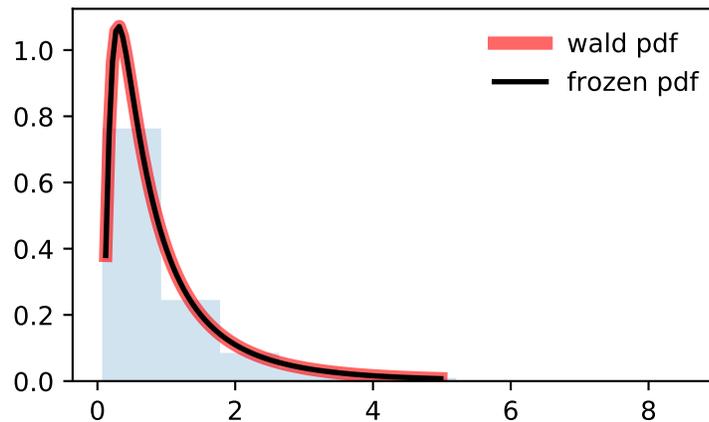

```
>>> vals = wald.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], wald.cdf(vals))
True
```

Generate random numbers:

```
>>> r = wald.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.weibull_min = <scipy.stats.continuous_distns.weibull_min_gen object>`

Weibull minimum continuous random variable.

As an instance of the *rv\_continuous* class, *weibull\_min* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**`weibull_max`**Notes**

The probability density function for `weibull_min` is:

$$f(x, c) = cx^{c-1} \exp(-x^c)$$

for  $x > 0, c > 0$ .

`weibull_min` takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_min.pdf(x, c, loc, scale)` is identically equivalent to `weibull_min.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import weibull_min
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.79
>>> mean, var, skew, kurt = weibull_min.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_min.ppf(0.01, c),
...                 weibull_min.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_min.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='weibull_min pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_min(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

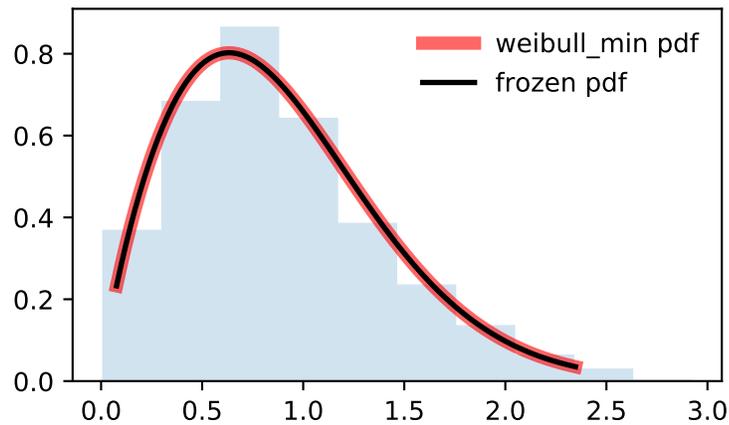

```
>>> vals = weibull_min.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_min.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_min.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.weibull_max = <scipy.stats.continuous_distns.weibull_max_gen object>`

Weibull maximum continuous random variable.

As an instance of the *rv\_continuous* class, *weibull\_max* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**`weibull_min`**Notes**

The probability density function for `weibull_max` is:

$$f(x, c) = c(-x)^{c-1} \exp(-(-x)^c)$$

for  $x < 0, c > 0$ .

`weibull_max` takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_max.pdf(x, c, loc, scale)` is identically equivalent to `weibull_max.pdf(y, c) / scale` with  $y = (x - loc) / scale$ .

**Examples**

```
>>> from scipy.stats import weibull_max
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 2.87
>>> mean, var, skew, kurt = weibull_max.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_max.ppf(0.01, c),
...                 weibull_max.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_max.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='weibull_max pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_max(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

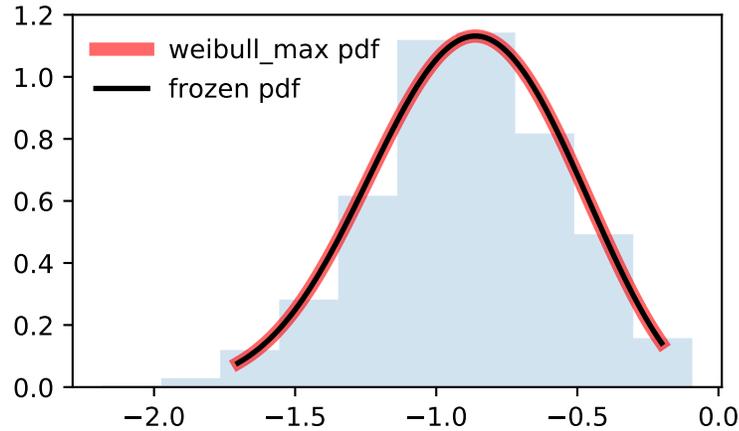

```
>>> vals = weibull_max.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_max.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_max.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.wrapcauchy = <scipy.stats.continuous_distns.wrapcauchy_gen object>`

A wrapped Cauchy continuous random variable.

As an instance of the *rv\_continuous* class, *wrapcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *wrapcauchy* is:

$$f(x, c) = \frac{1 - c^2}{2\pi(1 + c^2 - 2c \cos(x))}$$

for  $0 \leq x \leq 2\pi$ ,  $0 < c < 1$ .

*wrapcauchy* takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `wrapcauchy.pdf(x, c, loc, scale)` is identically equivalent to `wrapcauchy.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import wrapcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.0311
>>> mean, var, skew, kurt = wrapcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wrapcauchy.ppf(0.01, c),
...                 wrapcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, wrapcauchy.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='wrapcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wrapcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

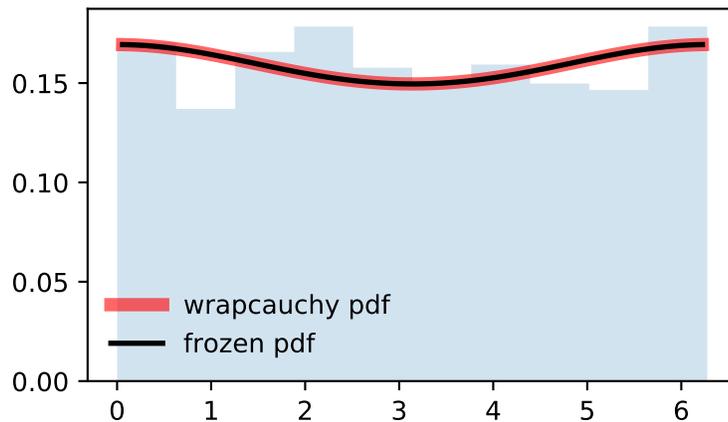

```
>>> vals = wrapcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], wrapcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = wrapcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).

## 5.27.2 Multivariate distributions

<code>multivariate_normal</code>	A multivariate normal random variable.
<code>matrix_normal</code>	A matrix normal random variable.
<code>dirichlet</code>	A Dirichlet random variable.
<code>wishart</code>	A Wishart random variable.
<code>invwishart</code>	An inverse Wishart random variable.
<code>multinomial</code>	A multinomial random variable.
<code>special_ortho_group</code>	A matrix-valued SO(N) random variable.
<code>ortho_group</code>	A matrix-valued O(N) random variable.
<code>unitary_group</code>	A matrix-valued U(N) random variable.
<code>random_correlation</code>	A random correlation matrix.

`scipy.stats.multivariate_normal` = <scipy.stats.\_multivariate.multivariate\_normal\_gen object>  
 A multivariate normal random variable.

The *mean* keyword specifies the mean. The *cov* keyword specifies the covariance matrix.

**Parameters** `x` : array\_like

Quantiles, with the last axis of *x* denoting the components.

**mean** : array\_like, optional

Mean of the distribution (default zero)

**cov** : array\_like, optional

Covariance matrix of the distribution (default one)

**allow\_singular** : bool, optional

Whether to allow a singular covariance matrix. (Default: False)

**random\_state** : None or int or np.random.RandomState instance, optional

If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” multivariate normal random variable:**

**rv = multivariate\_normal(mean=None, cov=1, allow\_singular=False)**

•Frozen object with the same methods but holding the given mean and covariance fixed.

### Notes

#### Setting the parameter mean to None is equivalent to having mean

be the zero-vector. The parameter *cov* can be a scalar, in which case the covariance matrix is the identity times that value, a vector of diagonal entries for the covariance matrix, or a two-dimensional array\_like.

The covariance matrix *cov* must be a (symmetric) positive semi-definite matrix. The determinant and inverse of *cov* are computed as the pseudo-determinant and pseudo-inverse, respectively, so that *cov* does not need to have full rank.

The probability density function for *multivariate\_normal* is

$$f(x) = \frac{1}{\sqrt{(2\pi)^k \det \Sigma}} \exp\left(-\frac{1}{2}(x - \mu)^T \Sigma^{-1}(x - \mu)\right),$$

where  $\mu$  is the mean,  $\Sigma$  the covariance matrix, and  $k$  is the dimension of the space where  $x$  takes values.

New in version 0.14.0.

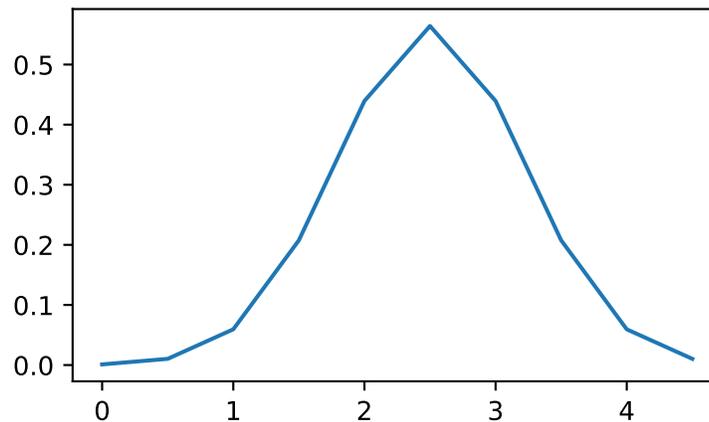

*Examples*

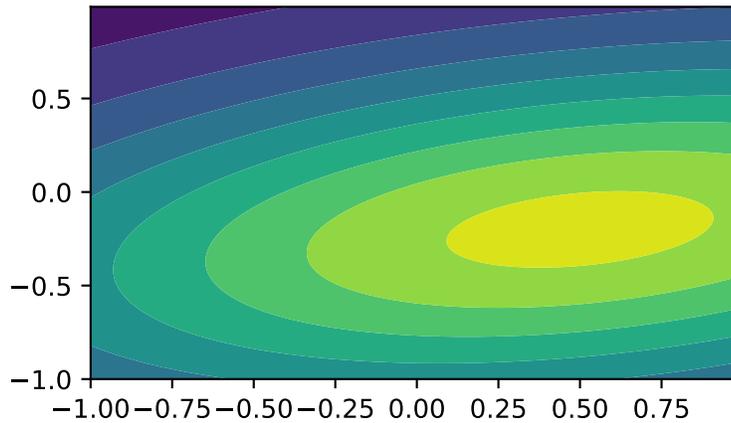

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_normal
```

```
>>> x = np.linspace(0, 5, 10, endpoint=False)
>>> y = multivariate_normal.pdf(x, mean=2.5, cov=0.5); y
array([ 0.00108914,  0.01033349,  0.05946514,  0.20755375,  0.43939129,
         0.56418958,  0.43939129,  0.20755375,  0.05946514,  0.01033349])
>>> fig1 = plt.figure()
>>> ax = fig1.add_subplot(111)
>>> ax.plot(x, y)
```

The input quantiles can be any shape of array, as long as the last axis labels the components. This allows us for instance to display the frozen pdf for a non-isotropic random variable in 2D as follows:

```
>>> x, y = np.mgrid[-1:1:.01, -1:1:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_normal([0.5, -0.2], [[2.0, 0.3], [0.3, 0.5]])
>>> fig2 = plt.figure()
>>> ax2 = fig2.add_subplot(111)
>>> ax2.contourf(x, y, rv.pdf(pos))
```

### Methods

<code>pdf(x, mean=None, cov=1, allow_singular=False)</code>	Probability density function.
<code>logpdf(x, mean=None, cov=1, allow_singular=False)</code>	Log of the probability density function.
<code>cdf(x, mean=None, cov=1, allow_singular=False, maxpts=1000000*dim, abseps=1e-5, releps=1e-5)</code>	Cumulative distribution function.
<code>logcdf(x, mean=None, cov=1, allow_singular=False, maxpts=1000000*dim, abseps=1e-5, releps=1e-5)</code>	Log of the cumulative distribution function.
<code>rvs(mean=None, cov=1, size=1, random_state=None)</code>	Draw random samples from a multivariate normal distribution.
<code>entropy()</code>	Compute the differential entropy of the multivariate normal.

`scipy.stats.matrix_normal = <scipy.stats.multivariate.matrix_normal_gen object>`

A matrix normal random variable.

The *mean* keyword specifies the mean. The *rowcov* keyword specifies the among-row covariance matrix. The *colcov* keyword specifies the among-column covariance matrix.

**Parameters** **X** : array\_like

Quantiles, with the last two axes of *X* denoting the components.

**mean** : array\_like, optional

Mean of the distribution (default: *None*)

**rowcov** : array\_like, optional

Among-row covariance matrix of the distribution (default: *I*)

**colcov** : array\_like, optional

Among-column covariance matrix of the distribution (default: *I*)

**random\_state** : None or int or `np.random.RandomState` instance, optional

If int or `RandomState`, use it for drawing the random variates. If *None* (or `np.random`), the global `np.random` state is used. Default is *None*.

**Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” matrix normal**

**random variable:**

**rv = matrix\_normal(mean=None, rowcov=1, colcov=1)**

- Frozen object with the same methods but holding the given mean and covariance fixed.

### Notes

**If mean is set to None then a matrix of zeros is used for the mean.**

The dimensions of this matrix are inferred from the shape of *rowcov* and *colcov*, if these are provided, or set to 1 if ambiguous.

*rowcov* and *colcov* can be two-dimensional array\_likes specifying the covariance matrices directly. Alternatively, a one-dimensional array will be interpreted as the entries of a diagonal matrix, and a scalar or zero-dimensional array will be interpreted as this value times the identity matrix.

The covariance matrices specified by *rowcov* and *colcov* must be (symmetric) positive definite. If the samples in *X* are  $m \times n$ , then *rowcov* must be  $m \times m$  and *colcov* must be  $n \times n$ . *mean* must be the same shape as *X*.

The probability density function for *matrix\_normal* is

$$f(X) = (2\pi)^{-\frac{mn}{2}} |U|^{-\frac{n}{2}} |V|^{-\frac{m}{2}} \exp\left(-\frac{1}{2} \text{Tr} [U^{-1}(X - M)V^{-1}(X - M)^T]\right),$$

where *M* is the mean, *U* the among-row covariance matrix, *V* the among-column covariance matrix.

The *allow\_singular* behaviour of the *multivariate\_normal* distribution is not currently supported. Covariance matrices must be full rank.

The *matrix\_normal* distribution is closely related to the *multivariate\_normal* distribution. Specifically,  $\text{Vec}(X)$  (the vector formed by concatenating the columns of *X*) has a multivariate normal distribution with mean  $\text{Vec}(M)$  and covariance  $V \otimes U$  (where  $\otimes$  is the Kronecker product). Sampling and pdf evaluation are  $\mathcal{O}(m^3 + n^3 + m^2n + mn^2)$  for the matrix normal, but  $\mathcal{O}(m^3n^3)$  for the equivalent multivariate normal, making this equivalent form algorithmically inefficient.

New in version 0.17.0.

### Examples

```
>>> from scipy.stats import matrix_normal
```

```
>>> M = np.arange(6).reshape(3,2); M
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> U = np.diag([1,2,3]); U
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3]])
>>> V = 0.3*np.identity(2); V
array([[ 0.3,  0. ],
       [ 0. ,  0.3]])
>>> X = M + 0.1; X
array([[ 0.1,  1.1],
       [ 2.1,  3.1],
       [ 4.1,  5.1]])
>>> matrix_normal.pdf(X, mean=M, rowcov=U, colcov=V)
0.023410202050005054
```

```

>>> # Equivalent multivariate normal
>>> from scipy.stats import multivariate_normal
>>> vectorised_X = X.T.flatten()
>>> equiv_mean = M.T.flatten()
>>> equiv_cov = np.kron(V,U)
>>> multivariate_normal.pdf(vectorised_X, mean=equiv_mean, cov=equiv_cov)
0.023410202050005054
    
```

### Methods

<code>pdf(X, mean=None, rowcov=1, colcov=1)</code>	Probability density function.
<code>logpdf(X, mean=None, rowcov=1, colcov=1)</code>	Log of the probability density function.
<code>rvs(mean=None, rowcov=1, colcov=1, size=1, random_state=None)</code>	Draw random samples.

`scipy.stats.dirichlet` = <scipy.stats.\_multivariate.dirichlet\_gen object>

A Dirichlet random variable.

The *alpha* keyword specifies the concentration parameters of the distribution.

New in version 0.15.0.

**Parameters** `x`: array\_like

Quantiles, with the last axis of *x* denoting the components.

**alpha**: array\_like

The concentration parameters. The number of entries determines the dimensionality of the distribution.

**random\_state**: None or int or np.random.RandomState instance, optional

If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**Alternatively, the object may be called (as a function) to fix concentration parameters, returning a “frozen” Dirichlet random variable:**

**rv = dirichlet(alpha)**

- Frozen object with the same methods but holding the given concentration parameters fixed.

### Notes

Each  $\alpha$  entry must be positive. The distribution has only support on the simplex defined by

$$\sum_{i=1}^K x_i \leq 1$$

The probability density function for *dirichlet* is

$$f(x) = \frac{1}{B(\boldsymbol{\alpha})} \prod_{i=1}^K x_i^{\alpha_i - 1}$$

where

$$B(\boldsymbol{\alpha}) = \frac{\prod_{i=1}^K \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^K \alpha_i)}$$

and  $\boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_K)$ , the concentration parameters and *K* is the dimension of the space where *x* takes values.

Note that the dirichlet interface is somewhat inconsistent. The array returned by the rvs function is transposed with respect to the format expected by the pdf and logpdf.

**Methods**

<code>pdf(x, alpha)</code>	Probability density function.
<code>logpdf(x, alpha)</code>	Log of the probability density function.
<code>rvs(alpha, size=1, random_state=None)</code>	Draw random samples from a Dirichlet distribution.
<code>mean(alpha)</code>	The mean of the Dirichlet distribution
<code>var(alpha)</code>	The variance of the Dirichlet distribution
<code>entropy(alpha)</code>	Compute the differential entropy of the Dirichlet distribution.

`scipy.stats.wishart` = <`scipy.stats._multivariate.wishart_gen` object>

A Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal precision matrix (the inverse of the covariance matrix).

**Parameters** `x` : array\_like

Quantiles, with the last axis of *x* denoting the components.

**df** : int

Degrees of freedom, must be greater than or equal to dimension of the scale matrix

**scale** : array\_like

Symmetric positive definite scale matrix of the distribution

**random\_state** : None or int or `np.random.RandomState` instance, optional

If int or `RandomState`, use it for drawing the random variates. If None (or `np.random`), the global `np.random` state is used. Default is None.

**Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” Wishart random variable:**

**rv = wishart(df=1, scale=1)**

•Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

**See also:**

`invwishart`, `chi2`

**Notes**

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The Wishart distribution is often denoted

$$W_p(\nu, \Sigma)$$

where  $\nu$  is the degrees of freedom and  $\Sigma$  is the  $p \times p$  scale matrix.

The probability density function for *wishart* has support over positive definite matrices *S*; if  $S \sim W_p(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|S|^{\frac{\nu-p-1}{2}}}{2^{\frac{\nu p}{2}} |\Sigma|^{\frac{p}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-tr(\Sigma^{-1}S)/2)$$

If  $S \sim W_p(\nu, \Sigma)$  (Wishart) then  $S^{-1} \sim W_p^{-1}(\nu, \Sigma^{-1})$  (inverse Wishart).

If the scale matrix is 1-dimensional and equal to one, then the Wishart distribution  $W_1(\nu, 1)$  collapses to the  $\chi^2(\nu)$  distribution.

New in version 0.16.0.

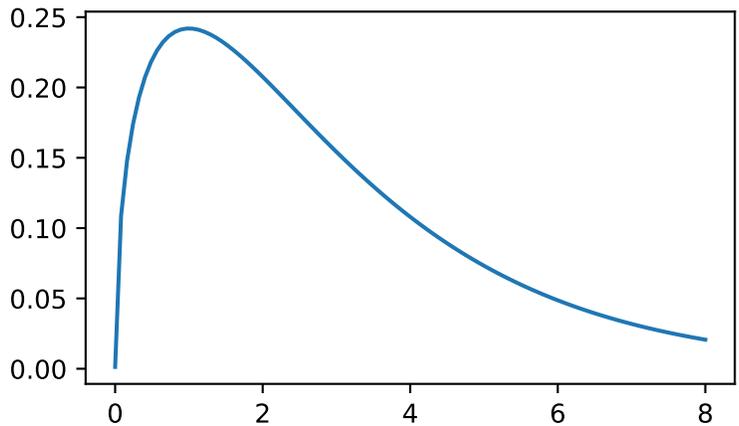

**References**

[R716], [R717]

**Examples**

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import wishart, chi2
>>> x = np.linspace(1e-5, 8, 100)
>>> w = wishart.pdf(x, df=3, scale=1); w[:5]
array([ 0.00126156,  0.10892176,  0.14793434,  0.17400548,  0.1929669  ])
>>> c = chi2.pdf(x, 3); c[:5]
array([ 0.00126156,  0.10892176,  0.14793434,  0.17400548,  0.1929669  ])
>>> plt.plot(x, w)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

**Methods**

pdf(x, df, scale)	Probability density function.
logpdf(x, df, scale)	Log of the probability density function.
rvs(df, scale, size=1, random_state=None)	Draw random samples from a Wishart distribution.
entropy()	Compute the differential entropy of the Wishart distribution.

scipy.stats.invwishart = <scipy.stats.\_multivariate.invwishart\_gen object>

An inverse Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal covariance matrix.

**Parameters** *x* : array\_like  
Quantiles, with the last axis of *x* denoting the components.  
*df* : int

Degrees of freedom, must be greater than or equal to dimension of the scale matrix

**scale** : array\_like

Symmetric positive definite scale matrix of the distribution

**random\_state** : None or int or np.random.RandomState instance, optional

If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” inverse Wishart random variable:**

**rv = invwishart(df=1, scale=1)**

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

**See also:**

*wishart*

**Notes**

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The inverse Wishart distribution is often denoted

$$W_p^{-1}(\nu, \Psi)$$

where  $\nu$  is the degrees of freedom and  $\Psi$  is the  $p \times p$  scale matrix.

The probability density function for *invwishart* has support over positive definite matrices  $S$ ; if  $S \sim W_p^{-1}(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|\Sigma|^{\frac{\nu}{2}}}{2^{\frac{\nu p}{2}} |S|^{\frac{\nu+p+1}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-tr(\Sigma S^{-1})/2)$$

If  $S \sim W_p^{-1}(\nu, \Psi)$  (inverse Wishart) then  $S^{-1} \sim W_p(\nu, \Psi^{-1})$  (Wishart).

If the scale matrix is 1-dimensional and equal to one, then the inverse Wishart distribution  $W_1(\nu, 1)$  collapses to the inverse Gamma distribution with parameters shape =  $\frac{\nu}{2}$  and scale =  $\frac{1}{2}$ .

New in version 0.16.0.

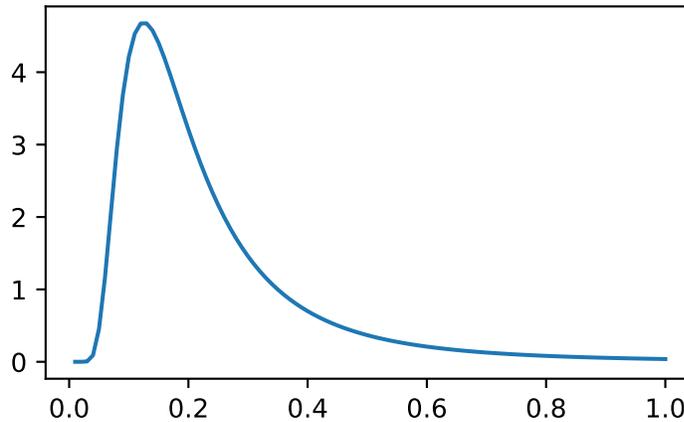

**References**

[R648], [R649]

**Examples**

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import invwishart, invgamma
>>> x = np.linspace(0.01, 1, 100)
>>> iw = invwishart.pdf(x, df=6, scale=1)
>>> iw[:3]
array([ 1.20546865e-15,  5.42497807e-06,  4.45813929e-03])
>>> ig = invgamma.pdf(x, 6/2., scale=1./2)
>>> ig[:3]
array([ 1.20546865e-15,  5.42497807e-06,  4.45813929e-03])
>>> plt.plot(x, iw)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

**Methods**

<code>pdf(x, df, scale)</code>	Probability density function.
<code>logpdf(x, df, scale)</code>	Log of the probability density function.
<code>rvs(df, scale, size=1, random_state=None)</code>	Draw random samples from an inverse Wishart distribution.

`scipy.stats.multinomial` = <scipy.stats.\_multivariate.multinomial\_gen object>

A multinomial random variable.

- Parameters**
- x** : array\_like  
Quantiles, with the last axis of *x* denoting the components.
  - n** : int  
Number of trials
  - p** : array\_like  
Probability of a trial falling into each category; should sum to 1
  - random\_state** : None or int or np.random.RandomState instance, optional  
If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**See also:**

- `scipy.stats.binom`  
The binomial distribution.
- `numpy.random.multinomial`  
Sampling from the multinomial distribution.

**Notes**

*n* should be a positive integer. Each element of *p* should be in the interval [0, 1] and the elements should sum to 1. If they do not sum to 1, the last element of the *p* array is not used and is replaced with the remaining probability left over from the earlier elements.

Alternatively, the object may be called (as a function) to fix the *n* and *p* parameters, returning a “frozen” multinomial random variable:

The probability mass function for *multinomial* is

$$f(x) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k},$$

supported on  $x = (x_1, \dots, x_k)$  where each  $x_i$  is a nonnegative integer and their sum is  $n$ .

New in version 0.19.0.

### Examples

```
>>> from scipy.stats import multinomial
>>> rv = multinomial(8, [0.3, 0.2, 0.5])
>>> rv.pmf([1, 3, 4])
0.0420000000000000072
```

The multinomial distribution for  $k = 2$  is identical to the corresponding binomial distribution (tiny numerical differences notwithstanding):

```
>>> from scipy.stats import binom
>>> multinomial.pmf([3, 4], n=7, p=[0.4, 0.6])
0.29030399999999973
>>> binom.pmf(3, 7, 0.4)
0.29030400000000012
```

The functions `pmf`, `logpmf`, `entropy`, and `cov` support broadcasting, under the convention that the vector parameters (`x` and `p`) are interpreted as if each row along the last axis is a single object. For instance:

```
>>> multinomial.pmf([[3, 4], [3, 5]], n=[7, 8], p=[.3, .7])
array([0.2268945, 0.25412184])
```

Here, `x.shape == (2, 2)`, `n.shape == (2,)`, and `p.shape == (2,)`, but following the rules mentioned above they behave as if the rows `[3, 4]` and `[3, 5]` in `x` and `[.3, .7]` in `p` were a single object, and as if we had `x.shape = (2,)`, `n.shape = (2,)`, and `p.shape = ()`. To obtain the individual elements without broadcasting, we would do this:

```
>>> multinomial.pmf([3, 4], n=7, p=[.3, .7])
0.2268945
>>> multinomial.pmf([3, 5], 8, p=[.3, .7])
0.25412184
```

This broadcasting also works for `cov`, where the output objects are square matrices of size `p.shape[-1]`. For example:

```
>>> multinomial.cov([4, 5], [[.3, .7], [.4, .6]])
array([[ [ 0.84, -0.84],
        [-0.84, 0.84]],
       [[ 1.2, -1.2 ],
        [-1.2, 1.2 ]]])
```

In this example, `n.shape == (2,)` and `p.shape == (2, 2)`, and following the rules above, these broadcast as if `p.shape == (2,)`. Thus the result should also be of shape `(2,)`, but since each output is a  $2 \times 2$  matrix, the result in fact has shape `(2, 2, 2)`, where `result[0]` is equal to `multinomial.cov(n=4, p=[.3, .7])` and `result[1]` is equal to `multinomial.cov(n=5, p=[.4, .6])`.

**Notes**

This class is closely related to `special_ortho_group`.

Some care is taken to avoid numerical error, as per the paper by Mezzadri.

**References**

[R678]

**Examples**

```
>>> from scipy.stats import ortho_group
>>> x = ortho_group.rvs(3)
```

```
>>> np.dot(x, x.T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])
```

```
>>> import scipy.linalg
>>> np.fabs(scipy.linalg.det(x))
1.0
```

This generates one random matrix from  $O(3)$ . It is orthogonal and has a determinant of +1 or -1.

**Methods**

<code>rvs(dim=None, size=1, random_state=None)</code>	Draw random samples from $O(N)$ .
---	-----------------------------------

`scipy.stats.unitary_group = <scipy.stats.multivariate.unitary_group_gen object>`

A matrix-valued  $U(N)$  random variable.

Return a random unitary matrix.

The *dim* keyword specifies the dimension  $N$ .

**Parameters** **dim** : scalar  
Dimension of matrices

**Notes**

This class is similar to `ortho_group`.

**References**

[R708]

**Examples**

```
>>> from scipy.stats import unitary_group
>>> x = unitary_group.rvs(3)
```

```
>>> np.dot(x, x.conj().T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])
```

This generates one random matrix from  $U(3)$ . The dot product confirms that it is unitary up to machine precision.

**Methods**

<code>rvs(dim=None, size=1, random_state=None)</code>	Draw random samples from U(N).
---	--------------------------------

`scipy.stats.random_correlation = <scipy.stats.multivariate.random_correlation_gen object>`

A random correlation matrix.

Return a random correlation matrix, given a vector of eigenvalues.

The *eigs* keyword specifies the eigenvalues of the correlation matrix, and implies the dimension.

**Parameters** *eigs* : 1d ndarray  
Eigenvalues of correlation matrix.

**Notes**

Generates a random correlation matrix following a numerically stable algorithm spelled out by Davies & Higham. This algorithm uses a single O(N) similarity transformation to construct a symmetric positive semi-definite matrix, and applies a series of Givens rotations to scale it to have ones on the diagonal.

**References**

[R689]

**Examples**

```
>>> from scipy.stats import random_correlation
>>> np.random.seed(514)
>>> x = random_correlation.rvs((.5, .8, 1.2, 1.5))
>>> x
array([[ 1.          , -0.20387311,  0.18366501, -0.04953711],
       [-0.20387311,  1.          , -0.24351129,  0.06703474],
       [ 0.18366501, -0.24351129,  1.          ,  0.38530195],
       [-0.04953711,  0.06703474,  0.38530195,  1.          ]])
```

```
>>> import scipy.linalg
>>> e, v = scipy.linalg.eigh(x)
>>> e
array([ 0.5,  0.8,  1.2,  1.5])
```

**Methods**

<code>rvs(eigs=None, random_state=None)</code>	Draw random correlation matrices, all with eigenvalues <i>eigs</i> .
--	--

**5.27.3 Discrete distributions**

<i>bernoulli</i>	A Bernoulli discrete random variable.
<i>binom</i>	A binomial discrete random variable.
<i>boltzmann</i>	A Boltzmann (Truncated Discrete Exponential) random variable.
<i>dlaplace</i>	A Laplacian discrete random variable.
<i>geom</i>	A geometric discrete random variable.
<i>hypergeom</i>	A hypergeometric discrete random variable.
<i>logser</i>	A Logarithmic (Log-Series, Series) discrete random variable.

Continued on next page

Table 5.289 – continued from previous page

<i>nbinom</i>	A negative binomial discrete random variable.
<i>planck</i>	A Planck discrete exponential random variable.
<i>poisson</i>	A Poisson discrete random variable.
<i>randint</i>	A uniform discrete random variable.
<i>skellam</i>	A Skellam discrete random variable.
<i>zipf</i>	A Zipf discrete random variable.

`scipy.stats.bernoulli` = <`scipy.stats.discrete_distns.bernoulli_gen` object>

A Bernoulli discrete random variable.

As an instance of the *rv\_discrete* class, *bernoulli* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for *bernoulli* is:

$$\begin{aligned} \text{bernoulli.pmf}(k) &= 1-p && \text{if } k = 0 \\ &= p && \text{if } k = 1 \end{aligned}$$

for  $k$  in  $\{0, 1\}$ .

*bernoulli* takes  $p$  as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `bernoulli.pmf(k, p, loc)` is identically equivalent to `bernoulli.pmf(k - loc, p)`.

### Examples

```
>>> from scipy.stats import bernoulli
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.3
>>> mean, var, skew, kurt = bernoulli.stats(p, moments='mvsk')
```

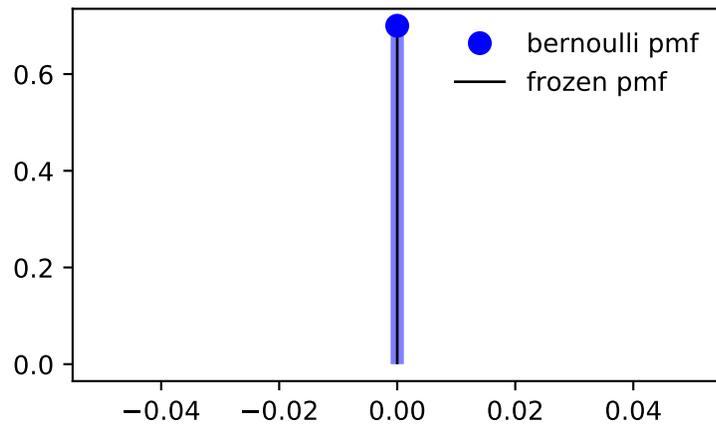

Display the probability mass function (pmf):

```
>>> x = np.arange(bernoulli.ppf(0.01, p),
...               bernoulli.ppf(0.99, p))
>>> ax.plot(x, bernoulli.pmf(x, p), 'bo', ms=8, label='bernoulli pmf')
>>> ax.vlines(x, 0, bernoulli.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = bernoulli(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = bernoulli.cdf(x, p)
>>> np.allclose(x, bernoulli.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = bernoulli.rvs(p, size=1000)
```

### Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.binom` = <`scipy.stats._discrete_distns.binom_gen` object>

A binomial discrete random variable.

As an instance of the `rv_discrete` class, `binom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `binom` is:

```
binom.pmf(k) = choose(n, k) * p**k * (1-p)**(n-k)
```

for `k` in  $\{0, 1, \dots, n\}$ .

`binom` takes `n` and `p` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `binom.pmf(k, n, p, loc)` is identically equivalent to `binom.pmf(k - loc, n, p)`.

### Examples

```
>>> from scipy.stats import binom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n, p = 5, 0.4
>>> mean, var, skew, kurt = binom.stats(n, p, moments='mvsk')
```

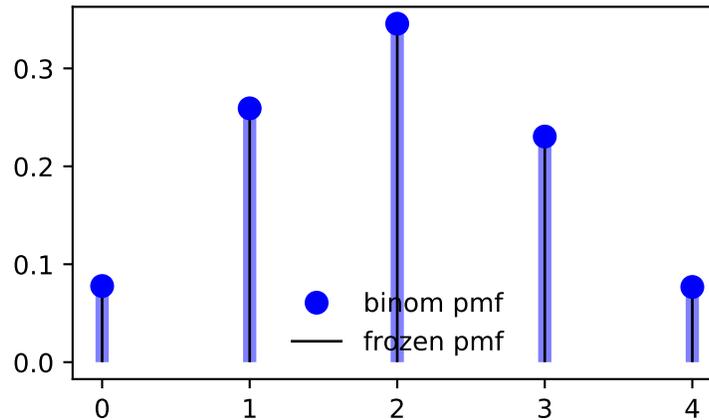

Display the probability mass function (pmf):

```
>>> x = np.arange(binom.ppf(0.01, n, p),
...               binom.ppf(0.99, n, p))
>>> ax.plot(x, binom.pmf(x, n, p), 'bo', ms=8, label='binom pmf')
>>> ax.vlines(x, 0, binom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = binom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = binom.cdf(x, n, p)
>>> np.allclose(x, binom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = binom.rvs(n, p, size=1000)
```

### Methods

<code>rvs(n, p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, n, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, n, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, n, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, n, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, n, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, n, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, n, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, n, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(n, p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(n, p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(n, p), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(n, p, loc=0)</code>	Median of the distribution.
<code>mean(n, p, loc=0)</code>	Mean of the distribution.
<code>var(n, p, loc=0)</code>	Variance of the distribution.
<code>std(n, p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, n, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.boltzmann = <scipy.stats._discrete_distns.boltzmann_gen object>`

A Boltzmann (Truncated Discrete Exponential) random variable.

As an instance of the `rv_discrete` class, `boltzmann` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `boltzmann` is:

$$\text{boltzmann.pmf}(k) = (1 - \exp(-\lambda)) \exp(-\lambda * k) / (1 - \exp(-\lambda * N))$$

for  $k = 0, \dots, N-1$ .

`boltzmann` takes `lambda_` and `N` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `boltzmann.pmf(k, lambda_, N, loc)` is identically equivalent to `boltzmann.pmf(k - loc, lambda_, N)`.

### Examples

```
>>> from scipy.stats import boltzmann
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lambda_, N = 1.4, 19
>>> mean, var, skew, kurt = boltzmann.stats(lambda_, N, moments='mvsk')
```

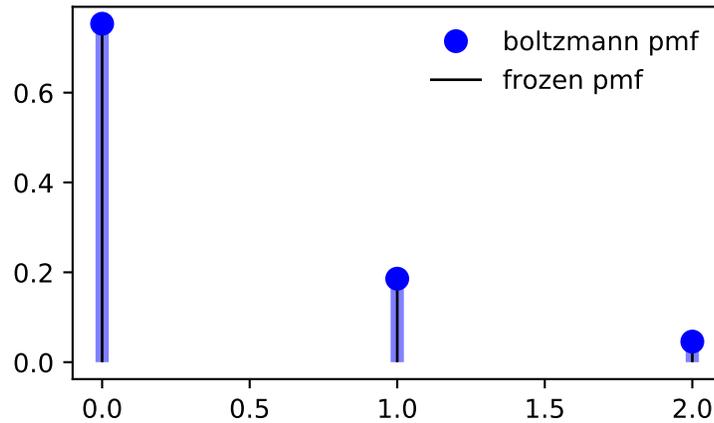

Display the probability mass function (pmf):

```
>>> x = np.arange(boltzmann.ppf(0.01, lambda_, N),
...               boltzmann.ppf(0.99, lambda_, N))
>>> ax.plot(x, boltzmann.pmf(x, lambda_, N), 'bo', ms=8, label='boltzmann pmf')
>>> ax.vlines(x, 0, boltzmann.pmf(x, lambda_, N), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = boltzmann(lambda_, N)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = boltzmann.cdf(x, lambda_, N)
>>> np.allclose(x, boltzmann.ppf(prob, lambda_, N))
True
```

Generate random numbers:

```
>>> r = boltzmann.rvs(lambda_, N, size=1000)
```

### Methods

<code>rvs(lambda_, N, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, lambda_, N, loc=0)</code>	Probability mass function.
<code>logpmf(k, lambda_, N, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, lambda_, N, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, lambda_, N, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, lambda_, N, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, lambda_, N, loc=0)</code>	Log of the survival function.
<code>ppf(q, lambda_, N, loc=0)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, lambda_, N, loc=0)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>stats(lambda_, N, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(lambda_, N, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(lambda_, N), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(lambda_, N, loc=0)</code>	Median of the distribution.
<code>mean(lambda_, N, loc=0)</code>	Mean of the distribution.
<code>var(lambda_, N, loc=0)</code>	Variance of the distribution.
<code>std(lambda_, N, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, lambda_, N, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.dlaplace = <scipy.stats._discrete_distns.dlaplace_gen object>`

A Laplacian discrete random variable.

As an instance of the `rv_discrete` class, `dlaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `dlaplace` is:

$$\text{dlaplace.pmf}(k) = \tanh(a/2) * \exp(-a*abs(k))$$

for  $a > 0$ .

`dlaplace` takes `a` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `dlaplace.pmf(k, a, loc)` is identically equivalent to `dlaplace.pmf(k - loc, a)`.

### Examples

```
>>> from scipy.stats import dlaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 0.8
>>> mean, var, skew, kurt = dlaplace.stats(a, moments='mvsk')
```

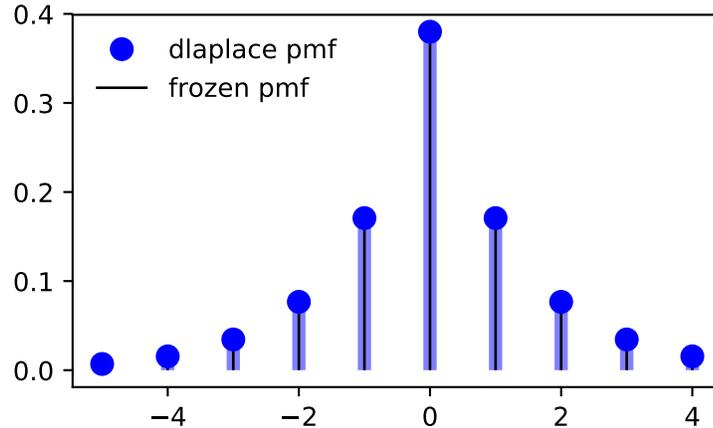

Display the probability mass function (pmf):

```
>>> x = np.arange(dlaplace.ppf(0.01, a),
...               dlaplace.ppf(0.99, a))
>>> ax.plot(x, dlaplace.pmf(x, a), 'bo', ms=8, label='dlaplace pmf')
>>> ax.vlines(x, 0, dlaplace.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = dlaplace(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = dlaplace.cdf(x, a)
>>> np.allclose(x, dlaplace.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = dlaplace.rvs(a, size=1000)
```

### Methods

<code>rvs(a, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, a, loc=0)</code>	Probability mass function.
<code>logpmf(k, a, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, a, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, a, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, a, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, a, loc=0)</code>	Log of the survival function.
<code>ppf(q, a, loc=0)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>stats(a, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(a,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0)</code>	Median of the distribution.
<code>mean(a, loc=0)</code>	Mean of the distribution.
<code>var(a, loc=0)</code>	Variance of the distribution.
<code>std(a, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.geom` = <`scipy.stats._discrete_distns.geom_gen` object>

A geometric discrete random variable.

As an instance of the `rv_discrete` class, `geom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `geom` is:

$$\text{geom.pmf}(k) = (1-p)^{k-1} * p$$

for  $k \geq 1$ .

`geom` takes `p` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `geom.pmf(k, p, loc)` is identically equivalent to `geom.pmf(k - loc, p)`.

### Examples

```
>>> from scipy.stats import geom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.5
>>> mean, var, skew, kurt = geom.stats(p, moments='mvsk')
```

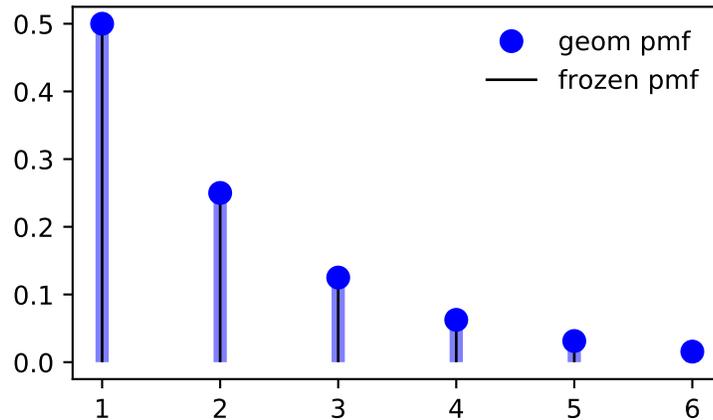

Display the probability mass function (pmf):

```
>>> x = np.arange(geom.ppf(0.01, p),
...               geom.ppf(0.99, p))
>>> ax.plot(x, geom.pmf(x, p), 'bo', ms=8, label='geom pmf')
>>> ax.vlines(x, 0, geom.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = geom(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = geom.cdf(x, p)
>>> np.allclose(x, geom.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = geom.rvs(p, size=1000)
```

### Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.hypergeom` = <scipy.stats.\_discrete\_distns.hypergeom\_gen object>

A hypergeometric discrete random variable.

The hypergeometric distribution models drawing objects from a bin.  $M$  is the total number of objects,  $n$  is total number of Type I objects. The random variate represents the number of Type I objects in  $N$  drawn without replacement from the total population.

As an instance of the `rv_discrete` class, `hypergeom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The symbols used to denote the shape parameters ( $M$ ,  $n$ , and  $N$ ) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$p(k, M, n, N) = \frac{\binom{n}{k} \binom{M-n}{N-k}}{\binom{M}{N}}$$

for  $k \in [\max(0, N - M + n), \min(n, N)]$ , where the binomial coefficients are defined as,

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}$$

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `hypergeom.pmf(k, M, n, N, loc)` is identically equivalent to `hypergeom.pmf(k - loc, M, n, N)`.

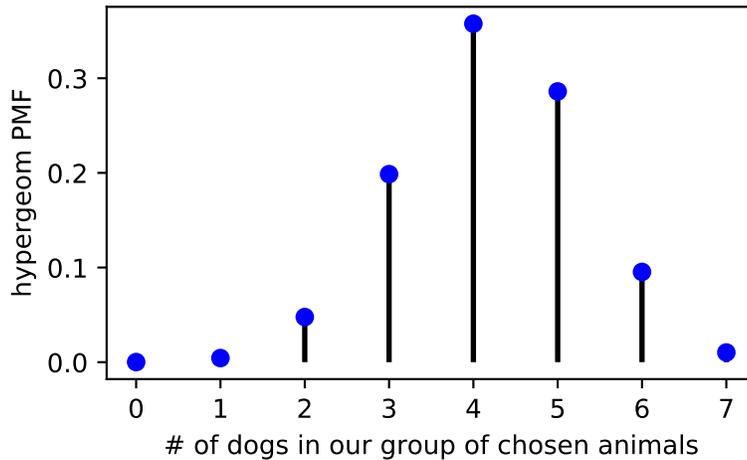

### Examples

```
>>> from scipy.stats import hypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs if we choose at random 12 of the 20 animals, we can initialize a frozen distribution and plot the probability mass function:

```
>>> [M, n, N] = [20, 7, 12]
>>> rv = hypergeom(M, n, N)
>>> x = np.arange(0, n+1)
>>> pmf_dogs = rv.pmf(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group of chosen animals')
>>> ax.set_ylabel('hypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use *hypergeom* methods directly. To for example obtain the cumulative distribution function, use:

```
>>> prb = hypergeom.cdf(x, M, n, N)
```

And to generate random numbers:

```
>>> R = hypergeom.rvs(M, n, N, size=10)
```

### Methods

<code>rvs(M, n, N, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, M, n, N, loc=0)</code>	Probability mass function.
<code>logpmf(k, M, n, N, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, M, n, N, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, M, n, N, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, M, n, N, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, M, n, N, loc=0)</code>	Log of the survival function.
<code>ppf(q, M, n, N, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, M, n, N, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(M, n, N, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(M, n, N, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(M, n, N), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(M, n, N, loc=0)</code>	Median of the distribution.
<code>mean(M, n, N, loc=0)</code>	Mean of the distribution.
<code>var(M, n, N, loc=0)</code>	Variance of the distribution.
<code>std(M, n, N, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, M, n, N, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.logser = <scipy.stats_discrete_distns.logser_gen object>`

A Logarithmic (Log-Series, Series) discrete random variable.

As an instance of the `rv_discrete` class, `logser` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `logser` is:

```
logser.pmf(k) = - p**k / (k*log(1-p))
```

for  $k \geq 1$ .

`logser` takes `p` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `logser.pmf(k, p, loc)` is identically equivalent to `logser.pmf(k - loc, p)`.

### Examples

```
>>> from scipy.stats import logser
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.6
>>> mean, var, skew, kurt = logser.stats(p, moments='mvsk')
```

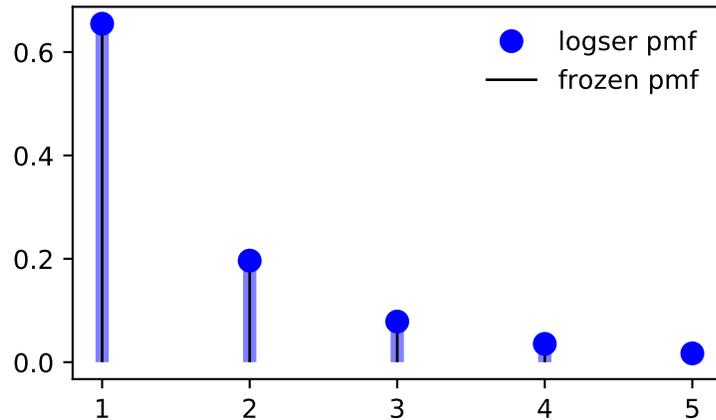

Display the probability mass function (pmf):

```
>>> x = np.arange(logser.ppf(0.01, p),
...               logser.ppf(0.99, p))
>>> ax.plot(x, logser.pmf(x, p), 'bo', ms=8, label='logser pmf')
>>> ax.vlines(x, 0, logser.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = logser(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = logser.cdf(x, p)
>>> np.allclose(x, logser.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = logser.rvs(p, size=1000)
```

### Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.nbinom` = <`scipy.stats._discrete_distns.nbinom_gen` object>

A negative binomial discrete random variable.

As an instance of the `rv_discrete` class, `nbinom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

Negative binomial distribution describes a sequence of i.i.d. Bernoulli trials, repeated until a predefined, non-random number of successes occurs.

The probability mass function of the number of failures for `nbinom` is:

$$\text{nbinom.pmf}(k) = \text{choose}(k+n-1, n-1) * p^{**n} * (1-p)^{**k}$$

for  $k \geq 0$ .

`nbinom` takes `n` and `p` as shape parameters where `n` is the number of successes, whereas `p` is the probability of a single success.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `nbinom.pmf(k, n, p, loc)` is identically equivalent to `nbinom.pmf(k - loc, n, p)`.

### Examples

```
>>> from scipy.stats import nbinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n, p = 0.4, 0.4
>>> mean, var, skew, kurt = nbinom.stats(n, p, moments='mvsk')
```

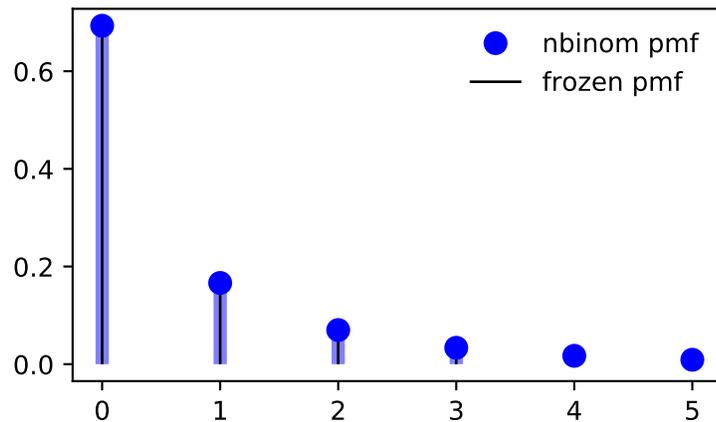

Display the probability mass function (pmf):

```
>>> x = np.arange(nbinom.ppf(0.01, n, p),
...               nbinom.ppf(0.99, n, p))
>>> ax.plot(x, nbinom.pmf(x, n, p), 'bo', ms=8, label='nbinom pmf')
>>> ax.vlines(x, 0, nbinom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = nbinom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = nbinom.cdf(x, n, p)
>>> np.allclose(x, nbinom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = nbinom.rvs(n, p, size=1000)
```

### Methods

<code>rvs(n, p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, n, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, n, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, n, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, n, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, n, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, n, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, n, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, n, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(n, p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(n, p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(n, p), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(n, p, loc=0)</code>	Median of the distribution.
<code>mean(n, p, loc=0)</code>	Mean of the distribution.
<code>var(n, p, loc=0)</code>	Variance of the distribution.
<code>std(n, p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, n, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.planck = <scipy.stats._discrete_distns.planck_gen object>`

A Planck discrete exponential random variable.

As an instance of the `rv_discrete` class, `planck` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `planck` is:

```
planck.pmf(k) = (1-exp(-lambda_)) * exp(-lambda_*k)
```

for  $k * \text{lambda\_} \geq 0$ .

`planck` takes `lambda_` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `planck.pmf(k, lambda_, loc)` is identically equivalent to `planck.pmf(k - loc, lambda_)`.

### Examples

```
>>> from scipy.stats import planck
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lambda_ = 0.51
>>> mean, var, skew, kurt = planck.stats(lambda_, moments='mvsk')
```

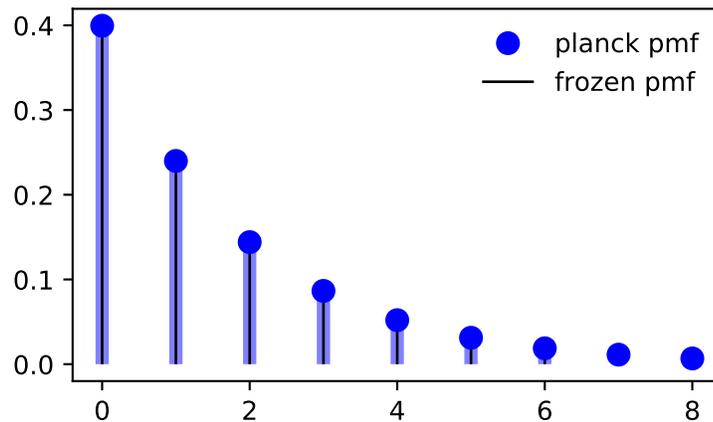

Display the probability mass function (pmf):

```
>>> x = np.arange(planck.ppf(0.01, lambda_),
...               planck.ppf(0.99, lambda_))
>>> ax.plot(x, planck.pmf(x, lambda_), 'bo', ms=8, label='planck pmf')
>>> ax.vlines(x, 0, planck.pmf(x, lambda_), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = planck(lambda_)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = planck.cdf(x, lambda_)
>>> np.allclose(x, planck.ppf(prob, lambda_))
True
```

Generate random numbers:

```
>>> r = planck.rvs(lambda_, size=1000)
```

### Methods

<code>rvs(lambda_, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, lambda_, loc=0)</code>	Probability mass function.
<code>logpmf(k, lambda_, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, lambda_, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, lambda_, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, lambda_, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, lambda_, loc=0)</code>	Log of the survival function.
<code>ppf(q, lambda_, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, lambda_, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(lambda_, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(lambda_, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(lambda_,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(lambda_, loc=0)</code>	Median of the distribution.
<code>mean(lambda_, loc=0)</code>	Mean of the distribution.
<code>var(lambda_, loc=0)</code>	Variance of the distribution.
<code>std(lambda_, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, lambda_, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.poisson` = <`scipy.stats._discrete_distns.poisson_gen` object>

A Poisson discrete random variable.

As an instance of the `rv_discrete` class, `poisson` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `poisson` is:

```
poisson.pmf(k) = exp(-mu) * mu**k / k!
```

for  $k \geq 0$ .

`poisson` takes `mu` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `poisson.pmf(k, mu, loc)` is identically equivalent to `poisson.pmf(k - loc, mu)`.

### Examples

```
>>> from scipy.stats import poisson
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.6
>>> mean, var, skew, kurt = poisson.stats(mu, moments='mvsk')
```

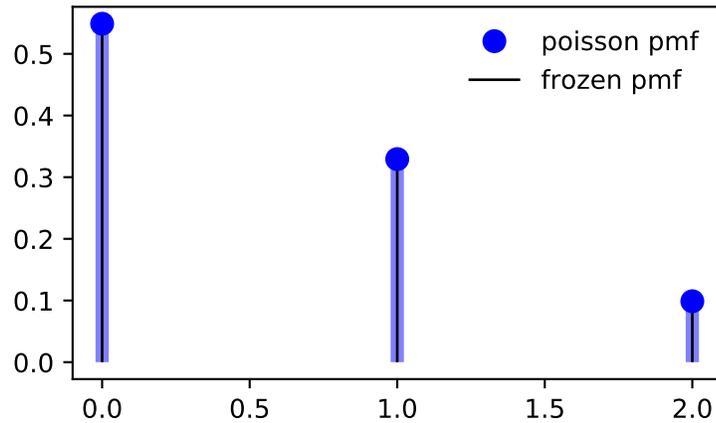

Display the probability mass function (pmf):

```
>>> x = np.arange(poisson.ppf(0.01, mu),
...               poisson.ppf(0.99, mu))
>>> ax.plot(x, poisson.pmf(x, mu), 'bo', ms=8, label='poisson pmf')
>>> ax.vlines(x, 0, poisson.pmf(x, mu), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = poisson(mu)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = poisson.cdf(x, mu)
>>> np.allclose(x, poisson.ppf(prob, mu))
True
```

Generate random numbers:

```
>>> r = poisson.rvs(mu, size=1000)
```

### Methods

<code>rvs(mu, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, mu, loc=0)</code>	Probability mass function.
<code>logpmf(k, mu, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, mu, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, mu, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, mu, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, mu, loc=0)</code>	Log of the survival function.
<code>ppf(q, mu, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, mu, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(mu, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(mu, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(mu,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(mu, loc=0)</code>	Median of the distribution.
<code>mean(mu, loc=0)</code>	Mean of the distribution.
<code>var(mu, loc=0)</code>	Variance of the distribution.
<code>std(mu, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, mu, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.randint` = <`scipy.stats._discrete_distns.randint_gen` object>

A uniform discrete random variable.

As an instance of the `rv_discrete` class, `randint` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `randint` is:

```
randint.pmf(k) = 1./(high - low)
```

for `k = low, ..., high - 1`.

`randint` takes `low` and `high` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `randint.pmf(k, low, high, loc)` is identically equivalent to `randint.pmf(k - loc, low, high)`.

### Examples

```
>>> from scipy.stats import randint
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> low, high = 7, 31
>>> mean, var, skew, kurt = randint.stats(low, high, moments='mvsk')
```

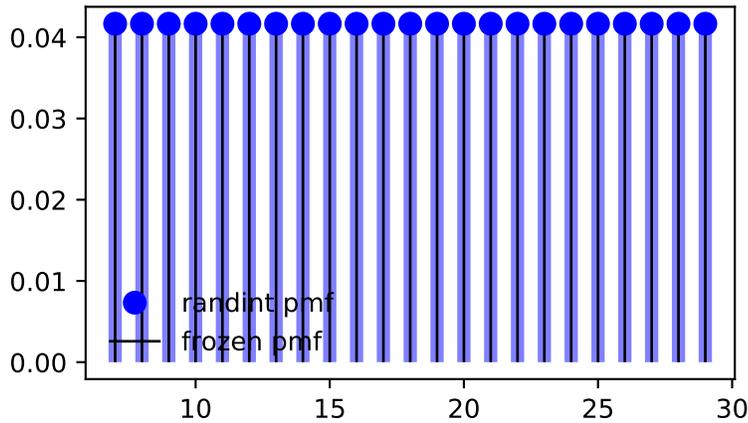

Display the probability mass function (pmf):

```
>>> x = np.arange(randint.ppf(0.01, low, high),
...               randint.ppf(0.99, low, high))
>>> ax.plot(x, randint.pmf(x, low, high), 'bo', ms=8, label='randint pmf')
>>> ax.vlines(x, 0, randint.pmf(x, low, high), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = randint(low, high)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = randint.cdf(x, low, high)
>>> np.allclose(x, randint.ppf(prob, low, high))
True
```

Generate random numbers:

```
>>> r = randint.rvs(low, high, size=1000)
```

### Methods

<code>rvs(low, high, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, low, high, loc=0)</code>	Probability mass function.
<code>logpmf(k, low, high, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, low, high, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, low, high, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, low, high, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, low, high, loc=0)</code>	Log of the survival function.
<code>ppf(q, low, high, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, low, high, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(low, high, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(low, high, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(low, high), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(low, high, loc=0)</code>	Median of the distribution.
<code>mean(low, high, loc=0)</code>	Mean of the distribution.
<code>var(low, high, loc=0)</code>	Variance of the distribution.
<code>std(low, high, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, low, high, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.skellam` = <`scipy.stats_discrete_distns.skellam_gen` object>

A Skellam discrete random variable.

As an instance of the `rv_discrete` class, `skellam` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

Probability distribution of the difference of two correlated or uncorrelated Poisson random variables.

Let  $k_1$  and  $k_2$  be two Poisson-distributed r.v. with expected values  $\lambda_1$  and  $\lambda_2$ . Then,  $k_1 - k_2$  follows a Skellam distribution with parameters  $\mu_1 = \lambda_1 - \rho \cdot \sqrt{\lambda_1 \lambda_2}$  and  $\mu_2 = \lambda_2 - \rho \cdot \sqrt{\lambda_1 \lambda_2}$ , where  $\rho$  is the correlation coefficient between  $k_1$  and  $k_2$ . If the two Poisson-distributed r.v. are independent then  $\rho = 0$ .

Parameters  $\mu_1$  and  $\mu_2$  must be strictly positive.

For details see: [http://en.wikipedia.org/wiki/Skellam\\_distribution](http://en.wikipedia.org/wiki/Skellam_distribution)

`skellam` takes  $\mu_1$  and  $\mu_2$  as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `skellam.pmf(k, mu1, mu2, loc)` is identically equivalent to `skellam.pmf(k - loc, mu1, mu2)`.

### Examples

```
>>> from scipy.stats import skellam
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu1, mu2 = 15, 8
>>> mean, var, skew, kurt = skellam.stats(mu1, mu2, moments='mvsk')
```

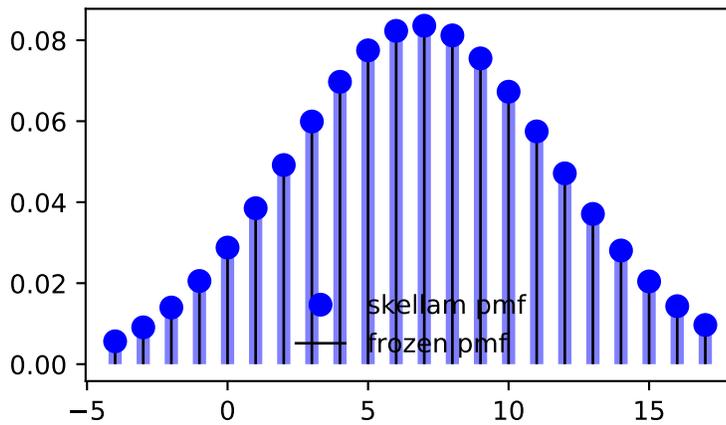

Display the probability mass function (pmf):

```
>>> x = np.arange(skellam.ppf(0.01, mu1, mu2),
...               skellam.ppf(0.99, mu1, mu2))
>>> ax.plot(x, skellam.pmf(x, mu1, mu2), 'bo', ms=8, label='skellam pmf')
>>> ax.vlines(x, 0, skellam.pmf(x, mu1, mu2), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = skellam(mu1, mu2)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = skellam.cdf(x, mu1, mu2)
>>> np.allclose(x, skellam.ppf(prob, mu1, mu2))
True
```

Generate random numbers:

```
>>> r = skellam.rvs(mu1, mu2, size=1000)
```

### Methods

<code>rvs(mu1, mu2, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, mu1, mu2, loc=0)</code>	Probability mass function.
<code>logpmf(k, mu1, mu2, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, mu1, mu2, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, mu1, mu2, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, mu1, mu2, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, mu1, mu2, loc=0)</code>	Log of the survival function.
<code>ppf(q, mu1, mu2, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, mu1, mu2, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(mu1, mu2, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(mu1, mu2, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(mu1, mu2), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(mu1, mu2, loc=0)</code>	Median of the distribution.
<code>mean(mu1, mu2, loc=0)</code>	Mean of the distribution.
<code>var(mu1, mu2, loc=0)</code>	Variance of the distribution.
<code>std(mu1, mu2, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, mu1, mu2, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.zipf` = <scipy.stats.\_discrete\_distns.zipf\_gen object>

A Zipf discrete random variable.

As an instance of the `rv_discrete` class, `zipf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `zipf` is:

```
zipf.pmf(k, a) = 1/(zeta(a) * k**a)
```

for  $k \geq 1$ .

`zipf` takes `a` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `zipf.pmf(k, a, loc)` is identically equivalent to `zipf.pmf(k - loc, a)`.

### Examples

```
>>> from scipy.stats import zipf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 6.5
>>> mean, var, skew, kurt = zipf.stats(a, moments='mvsk')
```

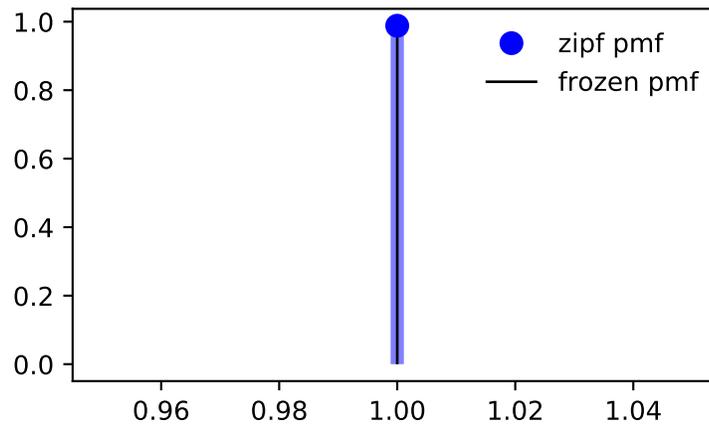

Display the probability mass function (pmf):

```
>>> x = np.arange(zipf.ppf(0.01, a),
...               zipf.ppf(0.99, a))
>>> ax.plot(x, zipf.pmf(x, a), 'bo', ms=8, label='zipf pmf')
>>> ax.vlines(x, 0, zipf.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = zipf(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = zipf.cdf(x, a)
>>> np.allclose(x, zipf.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = zipf.rvs(a, size=1000)
```

### Methods

<code>rvs(a, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, a, loc=0)</code>	Probability mass function.
<code>logpmf(k, a, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, a, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, a, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, a, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, a, loc=0)</code>	Log of the survival function.
<code>ppf(q, a, loc=0)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>stats(a, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(a,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0)</code>	Median of the distribution.
<code>mean(a, loc=0)</code>	Mean of the distribution.
<code>var(a, loc=0)</code>	Variance of the distribution.
<code>std(a, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## 5.27.4 Statistical functions

Several of these functions have a similar version in `scipy.stats.mstats` which work for masked arrays.

<code>describe(a[, axis, ddof, bias, nan_policy])</code>	Compute several descriptive statistics of the passed array.
<code>gmean(a[, axis, dtype])</code>	Compute the geometric mean along the specified axis.
<code>hmean(a[, axis, dtype])</code>	Calculate the harmonic mean along the specified axis.
<code>kurtosis(a[, axis, fisher, bias, nan_policy])</code>	Compute the kurtosis (Fisher or Pearson) of a dataset.
<code>kurtosistest(a[, axis, nan_policy])</code>	Test whether a dataset has normal kurtosis.
<code>mode(a[, axis, nan_policy])</code>	Return an array of the modal (most common) value in the passed array.
<code>moment(a[, moment, axis, nan_policy])</code>	Calculate the nth moment about the mean for a sample.
<code>normaltest(a[, axis, nan_policy])</code>	Test whether a sample differs from a normal distribution.
<code>skew(a[, axis, bias, nan_policy])</code>	Compute the skewness of a data set.
<code>skewtest(a[, axis, nan_policy])</code>	Test whether the skew is different from the normal distribution.
<code>kstat(data[, n])</code>	Return the nth k-statistic ( $1 \leq n \leq 4$ so far).
<code>kstatvar(data[, n])</code>	Returns an unbiased estimator of the variance of the k-statistic.
<code>tmean(a[, limits, inclusive, axis])</code>	Compute the trimmed mean.
<code>tvar(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed variance.
<code>tmin(a[, lowerlimit, axis, inclusive, ...])</code>	Compute the trimmed minimum.
<code>tmax(a[, upperlimit, axis, inclusive, ...])</code>	Compute the trimmed maximum.
<code>tstd(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed sample standard deviation.
<code>tsem(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed standard error of the mean.
<code>variation(a[, axis, nan_policy])</code>	Compute the coefficient of variation, the ratio of the biased standard deviation to the mean.
<code>find_repeats(arr)</code>	Find repeats and repeat counts.
<code>trim_mean(a, proportiontocut[, axis])</code>	Return mean of array after trimming distribution from both tails.

`scipy.stats.describe(a, axis=0, ddof=1, bias=True, nan_policy='propagate')`

Compute several descriptive statistics of the passed array.

**Parameters** **a** : array\_like

Input data.

**axis** : int or None, optional

Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.

**ddof** : int, optional

Delta degrees of freedom (only for variance). Default is 1.

**bias** : bool, optional

If False, then the skewness and kurtosis calculations are corrected for statistical bias.

**nan\_policy** : { 'propagate', 'raise', 'omit' }, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**nobs** : int or ndarray of ints

Number of observations (length of data along *axis*). When 'omit' is chosen as *nan\_policy*, each column is counted separately.

**minmax**: tuple of ndarrays or floats

Minimum and maximum value of data array.

- mean** : ndarray or float  
Arithmetic mean of data along axis.
- variance** : ndarray or float  
Unbiased variance of the data along axis, denominator is number of observations minus one.
- skewness** : ndarray or float  
Skewness, based on moment calculations with denominator equal to the number of observations, i.e. no degrees of freedom correction.
- kurtosis** : ndarray or float  
Kurtosis (Fisher). The kurtosis is normalized so that it is zero for the normal distribution. No degrees of freedom are used.

**See also:**

*skew, kurtosis*

**Examples**

```
>>> from scipy import stats
>>> a = np.arange(10)
>>> stats.describe(a)
DescribeResult(nobs=10, minmax=(0, 9), mean=4.5, variance=9.1666666666666661,
              skewness=0.0, kurtosis=-1.2242424242424244)
>>> b = [[1, 2], [3, 4]]
>>> stats.describe(b)
DescribeResult(nobs=2, minmax=(array([1, 2]), array([3, 4])),
              mean=array([ 2., 3.]), variance=array([ 2., 2.]),
              skewness=array([ 0., 0.]), kurtosis=array([-2., -2.]))
```

`scipy.stats.gmean(a, axis=0, dtype=None)`

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is: n-th root of (x1 \* x2 \* ... \* xn)

- Parameters**

  - a** : array\_like  
Input array or object that can be converted to an array.
  - axis** : int or None, optional  
Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array *a*.
  - dtype** : dtype, optional  
Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

- Returns**

  - gmean** : ndarray  
see dtype parameter above

**See also:**

- numpy.mean* Arithmetic average
- numpy.average*  
Weighted average
- hmean** Harmonic mean

**Notes**

The geometric average is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

### Examples

```
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

`scipy.stats.hmean(a, axis=0, dtype=None)`

Calculate the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

**Parameters**    **a** : array\_like

Input array, masked array or object that can be converted to an array.

**axis** : int or None, optional

Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.

**dtype** : dtype, optional

Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer *dtype* with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

**hmean** : ndarray

see *dtype* parameter above

See also:

`numpy.mean` Arithmetic average

`numpy.average`

Weighted average

`gmean`

Geometric mean

### Notes

The harmonic mean is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

### Examples

```
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

`scipy.stats.kurtosis(a, axis=0, fisher=True, bias=True, nan_policy='propagate')`

Compute the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If `bias` is False then the kurtosis is calculated using *k* statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

**Parameters**

- a** : array  
data for which the kurtosis is calculated
- axis** : int or None, optional  
Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array *a*.
- fisher** : bool, optional  
If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).
- bias** : bool, optional  
If False, then the calculations are corrected for statistical bias.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- kurtosis** : array  
The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.

**References**

[R660]

**Examples**

```
>>> from scipy.stats import kurtosis
>>> kurtosis([1, 2, 3, 4, 5])
-1.3
```

`scipy.stats.kurtosistest` (*a*, *axis*=0, *nan\_policy*='propagate')

Test whether a dataset has normal kurtosis.

This function tests the null hypothesis that the kurtosis of the population from which the sample was drawn is that of the normal distribution:  $kurtosis = 3(n-1)/(n+1)$ .

**Parameters**

- a** : array  
array of the sample data
- axis** : int or None, optional  
Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- statistic** : float  
The computed z-score for this test.
- pvalue** : float  
The 2-sided p-value for the hypothesis test

**Notes**

Valid only for  $n > 20$ . The Z-score is set to 0 for bad entries. This function uses the method described in [R661].

**References**

[R661]

**Examples**

```
>>> from scipy.stats import kurtosistest
>>> kurtosistest(list(range(20)))
KurtosistestResult(statistic=-1.7058104152122062, pvalue=0.088043383325283484)
```

```
>>> np.random.seed(28041990)
>>> s = np.random.normal(0, 1, 1000)
>>> kurtosistest(s)
KurtosistestResult(statistic=1.2317590987707365, pvalue=0.21803908613450895)
```

`scipy.stats.mode` (*a*, *axis=0*, *nan\_policy='propagate'*)

Return an array of the modal (most common) value in the passed array.

If there is more than one such value, only the smallest is returned. The bin-count for the modal bins is also returned.

**Parameters**

- a** : array\_like  
n-dimensional array of which to find mode(s).
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- mode** : ndarray  
Array of modal values.
- count** : ndarray  
Array of counts for each mode.

**Examples**

```
>>> a = np.array([[6, 8, 3, 0],
...              [3, 2, 1, 7],
...              [8, 1, 8, 4],
...              [5, 3, 0, 5],
...              [4, 7, 5, 9]])
>>> from scipy import stats
>>> stats.mode(a)
(array([[3, 1, 0, 0]]), array([[1, 1, 1, 1]]))
```

To get mode of whole array, specify *axis=None*:

```
>>> stats.mode(a, axis=None)
(array([3]), array([3]))
```

`scipy.stats.moment` (*a*, *moment=1*, *axis=0*, *nan\_policy='propagate'*)

Calculate the *n*th moment about the mean for a sample.

A moment is a specific quantitative measure of the shape of a set of points. It is often used to calculate coefficients of skewness and kurtosis due to its close relationship with them.

**Parameters**

- a** : array\_like  
data
- moment** : int or array\_like of ints, optional  
order of central moment that is returned. Default is 1.
- axis** : int or None, optional

Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.

**nan\_policy** : { 'propagate', 'raise', 'omit' }, optional  
 Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns** **n-th central moment** : ndarray or float  
 The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**See also:**

*kurtosis*, *skew*, *describe*

**Notes**

The k-th central moment of a data sample is:

$$m_k = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^k$$

Where n is the number of samples and x-bar is the mean. This function uses exponentiation by squares [R670] for efficiency.

**References**

[R670]

**Examples**

```
>>> from scipy.stats import moment
>>> moment([1, 2, 3, 4, 5], moment=1)
0.0
>>> moment([1, 2, 3, 4, 5], moment=2)
2.0
```

`scipy.stats.normaltest` (*a*, *axis*=0, *nan\_policy*='propagate')

Test whether a sample differs from a normal distribution.

This function tests the null hypothesis that a sample comes from a normal distribution. It is based on D'Agostino and Pearson's [R675], [R676] test that combines skew and kurtosis to produce an omnibus test of normality.

**Parameters** **a** : array\_like  
 The array containing the sample to be tested.

**axis** : int or None, optional  
 Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

**nan\_policy** : { 'propagate', 'raise', 'omit' }, optional  
 Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns** **statistic** : float or array  
 $s^2 + k^2$ , where *s* is the z-score returned by *skewtest* and *k* is the z-score returned by *kurtosistest*.

**pvalue** : float or array  
 A 2-sided chi squared probability for the hypothesis test.

**References**

[R675], [R676]

**Examples**

```

>>> from scipy import stats
>>> pts = 1000
>>> np.random.seed(28041990)
>>> a = np.random.normal(0, 1, size=pts)
>>> b = np.random.normal(2, 1, size=pts)
>>> x = np.concatenate((a, b))
>>> k2, p = stats.normaltest(x)
>>> alpha = 1e-3
>>> print("p = {:g}".format(p))
p = 3.27207e-11
>>> if p < alpha: # null hypothesis: x comes from a normal distribution
...     print("The null hypothesis can be rejected")
... else:
...     print("The null hypothesis cannot be rejected")
The null hypothesis can be rejected

```

`scipy.stats.skew` (*a*, *axis*=0, *bias*=True, *nan\_policy*='propagate')

Compute the skewness of a data set.

For normally distributed data, the skewness should be about 0. For unimodal continuous distributions, a skewness value > 0 means that there is more weight in the right tail of the distribution. The function `skewtest` can be used to determine if the skewness value is close enough to 0, statistically speaking.

**Parameters** **a** : ndarray

data

**axis** : int or None, optional

Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.

**bias** : bool, optional

If False, then the calculations are corrected for statistical bias.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**skewness** : ndarray

The skewness of values along an axis, returning 0 where all values are equal.

**References**

[R696]

**Examples**

```

>>> from scipy.stats import skew
>>> skew([1, 2, 3, 4, 5])
0.0
>>> skew([2, 8, 0, 4, 1, 9, 9, 0])
0.2650554122698573

```

`scipy.stats.skewtest` (*a*, *axis*=0, *nan\_policy*='propagate')

Test whether the skew is different from the normal distribution.

This function tests the null hypothesis that the skewness of the population that the sample was drawn from is the same as that of a corresponding normal distribution.

**Parameters**

- a** : array  
The data to be tested
- axis** : int or None, optional  
Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- statistic** : float  
The computed z-score for this test.
- pvalue** : float  
a 2-sided p-value for the hypothesis test

**Notes**

The sample size must be at least 8.

**References**

[R698]

**Examples**

```
>>> from scipy.stats import skewtest
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8])
SkewtestResult(statistic=1.0108048609177787, pvalue=0.31210983614218968)
>>> skewtest([2, 8, 0, 4, 1, 9, 9, 0])
SkewtestResult(statistic=0.44626385374196975, pvalue=0.65540666312754592)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8000])
SkewtestResult(statistic=3.5717735103604071, pvalue=0.00035457199058231331)
>>> skewtest([100, 100, 100, 100, 100, 100, 100, 101])
SkewtestResult(statistic=3.5717766638478072, pvalue=0.000354567720281634)
```

`scipy.stats.kstat` (*data*, *n=2*)  
Return the *n*th k-statistic (1<=*n*<=4 so far).

The *n*th k-statistic *k<sub>n</sub>* is the unique symmetric unbiased estimator of the *n*th cumulant *kappa<sub>n</sub>*.

**Parameters**

- data** : array\_like  
Input array. Note that n-D input gets flattened.
- n** : int, {1, 2, 3, 4}, optional  
Default is equal to 2.

**Returns**

- kstat** : float  
The *n*th k-statistic.

**See also:**

**kstatvar** Returns an unbiased estimator of the variance of the k-statistic.  
**moment** Returns the *n*-th central moment about the mean for a sample.

**Notes**

For a sample size *n*, the first few k-statistics are given by:

$$k_1 = \mu k_2 = \frac{n}{n-1} m_2 k_3 = \frac{n^2}{(n-1)(n-2)} m_3 k_4 = \frac{n^2[(n+1)m_4 - 3(n-1)m_2^2]}{(n-1)(n-2)(n-3)}$$

where  $\mu$  is the sample mean,  $m_2$  is the sample variance, and  $m_i$  is the *i*-th sample central moment.

## References

<http://mathworld.wolfram.com/k-Statistic.html>

<http://mathworld.wolfram.com/Cumulant.html>

## Examples

```
>>> from scipy import stats
>>> rndm = np.random.RandomState(1234)
```

As sample size increases, n-th moment and n-th k-statistic converge to the same number (although they aren't identical). In the case of the normal distribution, they converge to zero.

```
>>> for n in [2, 3, 4, 5, 6, 7]:
...     x = rndm.normal(size=10**n)
...     m, k = stats.moment(x, 3), stats.kstat(x, 3)
...     print("%.3g %.3g %.3g" % (m, k, m-k))
-0.631 -0.651 0.0194
0.0282 0.0283 -8.49e-05
-0.0454 -0.0454 1.36e-05
7.53e-05 7.53e-05 -2.26e-09
0.00166 0.00166 -4.99e-09
-2.88e-06 -2.88e-06 8.63e-13
```

`scipy.stats.kstatvar` (*data*, *n*=2)

Returns an unbiased estimator of the variance of the k-statistic.

See *kstat* for more details of the k-statistic.

**Parameters**

- data** : array\_like  
Input array. Note that n-D input gets flattened.
- n** : int, {1, 2}, optional  
Default is equal to 2.

**Returns**

- kstatvar** : float  
The nth k-statistic variance.

See also:

**kstat** Returns the n-th k-statistic.  
**moment** Returns the n-th central moment about the mean for a sample.

## Notes

The variances of the first few k-statistics are given by:

$$\text{var}(k_1) = \frac{\kappa^2}{n} \text{var}(k_2) = \frac{\kappa^4}{n} + \frac{2\kappa_2^2}{n-1} \text{var}(k_3) = \frac{\kappa^6}{n} + \frac{9\kappa_2\kappa_4}{n-1} + \frac{9\kappa_3^2}{n-1} + \frac{6n\kappa_2^3}{(n-1)(n-2)} \text{var}(k_4) = \frac{\kappa^8}{n} + \frac{16\kappa_2\kappa_6}{n-1} + \frac{48\kappa_3\kappa_5}{n-1}$$

`scipy.stats.tmean` (*a*, *limits*=None, *inclusive*=(True, True), *axis*=None)

Compute the trimmed mean.

This function finds the arithmetic mean of given values, ignoring values outside the given *limits*.

**Parameters**

- a** : array\_like  
Array of values.
- limits** : None or (lower limit, upper limit), optional  
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.

**inclusive** : (bool, bool), optional  
 A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** : int or None, optional  
 Axis along which to compute test. Default is None.

**Returns** **tmean** : float

**See also:**

**trim\_mean** returns mean after trimming a proportion from both tails.

**Examples**

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmean(x)
9.5
>>> stats.tmean(x, (3,17))
10.0
```

`scipy.stats.tvar(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed variance.

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

**Parameters** **a** : array\_like

Array of values.

**limits** : None or (lower limit, upper limit), optional

Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** : (bool, bool), optional

A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** : int or None, optional

Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**ddof** : int, optional

Delta degrees of freedom. Default is 1.

**Returns** **tvar** : float

Trimmed variance.

**Notes**

*tvar* computes the unbiased sample variance, i.e. it uses a correction factor  $n / (n - 1)$ .

**Examples**

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tvar(x)
35.0
>>> stats.tvar(x, (3,17))
20.0
```

`scipy.stats.tmin(a, lowerlimit=None, axis=0, inclusive=True, nan_policy='propagate')`

Compute the trimmed minimum.

This function finds the minimum value of an array *a* along the specified axis, but only considering values greater than a specified lower limit.

**Parameters**

- a** : array\_like  
array of values
- lowerlimit** : None or float, optional  
Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** : {True, False}, optional  
This flag determines whether values exactly equal to the lower limit are included. The default value is True.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- tmin** : float, int or ndarray

#### Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmin(x)
0
```

```
>>> stats.tmin(x, 13)
13
```

```
>>> stats.tmin(x, 13, inclusive=False)
14
```

`scipy.stats.tmax(a, upperlimit=None, axis=0, inclusive=True, nan_policy='propagate')`

Compute the trimmed maximum.

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- a** : array\_like  
array of values
- upperlimit** : None or float, optional  
Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** : {True, False}, optional  
This flag determines whether values exactly equal to the upper limit are included. The default value is True.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns** `tmax` : float, int or ndarray

### Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmax(x)
19
```

```
>>> stats.tmax(x, 13)
13
```

```
>>> stats.tmax(x, 13, inclusive=False)
12
```

`scipy.stats.tstd(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed sample standard deviation.

This function finds the sample standard deviation of given values, ignoring values outside the given *limits*.

**Parameters** `a` : array\_like

array of values

**limits** : None or (lower limit, upper limit), optional

Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** : (bool, bool), optional

A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** : int or None, optional

Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**ddof** : int, optional

Delta degrees of freedom. Default is 1.

**Returns** `tstd` : float

### Notes

*tstd* computes the unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

### Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tstd(x)
5.9160797830996161
>>> stats.tstd(x, (3, 17))
4.4721359549995796
```

`scipy.stats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

**Parameters** `a` : array\_like

array of values

**limits** : None or (lower limit, upper limit), optional  
 Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** : (bool, bool), optional  
 A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** : int or None, optional  
 Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**ddof** : int, optional  
 Delta degrees of freedom. Default is 1.

**Returns** **tsem** : float

### Notes

*tsem* uses unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

### Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tsem(x)
1.3228756555322954
>>> stats.tsem(x, (3, 17))
1.1547005383792515
```

`scipy.stats.variation` (*a*, *axis*=0, *nan\_policy*='propagate')

Compute the coefficient of variation, the ratio of the biased standard deviation to the mean.

**Parameters** **a** : array\_like  
 Input array.

**axis** : int or None, optional  
 Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
 Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns** **variation** : ndarray  
 The calculated variation along the requested axis.

### References

[R709]

### Examples

```
>>> from scipy.stats import variation
>>> variation([1, 2, 3, 4, 5])
0.47140452079103173
```

`scipy.stats.find_repeats` (*arr*)

Find repeats and repeat counts.

**Parameters** **arr** : array\_like  
 Input array. This is cast to float64.

<code>cumfreq(a[, numbins, defaultreallimits, weights])</code>	Return a cumulative frequency histogram, using the histogram function.
<code>itemfreq(a)</code>	Return a 2-D array of item frequencies.
<code>percentileofscore(a, score[, kind])</code>	The percentile rank of a score relative to a list of scores.
<code>scoreatpercentile(a, per[, limit, ...])</code>	Calculate the score at a given percentile of the input sequence.
<code>relfreq(a[, numbins, defaultreallimits, weights])</code>	Return a relative frequency histogram, using the histogram function.

`scipy.stats.cumfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a cumulative frequency histogram, using the histogram function.

A cumulative histogram is a mapping that counts the cumulative number of observations in all of the bins up to the specified bin.

**Parameters** **a** : array\_like

Input array.

**numbins** : int, optional

The number of bins to use for the histogram. Default is 10.

**defaultreallimits** : tuple (lower, upper), optional

The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.\text{min}() - s, a.\text{max}() + s)$ , where  $s = (1/2)(a.\text{max}() - a.\text{min}()) / (\text{numbins} - 1)$ .

**weights** : array\_like, optional

The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

**Returns**

**cumcount** : ndarray

Binned values of cumulative frequency.

**lowerlimit** : float

Lower real limit

**binsize** : float

Width of each bin.

**extrapoints** : int

Extra points.

### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> x = [1, 4, 2, 1, 3, 1]
>>> res = stats.cumfreq(x, numbins=4, defaultreallimits=(1.5, 5))
>>> res.cumcount
array([ 1.,  2.,  3.,  3.])
>>> res.extrapoints
3
```

Create a normal distribution with 1000 random values

```
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate cumulative frequencies

```
>>> res = stats.cumfreq(samples, numbins=25)
```

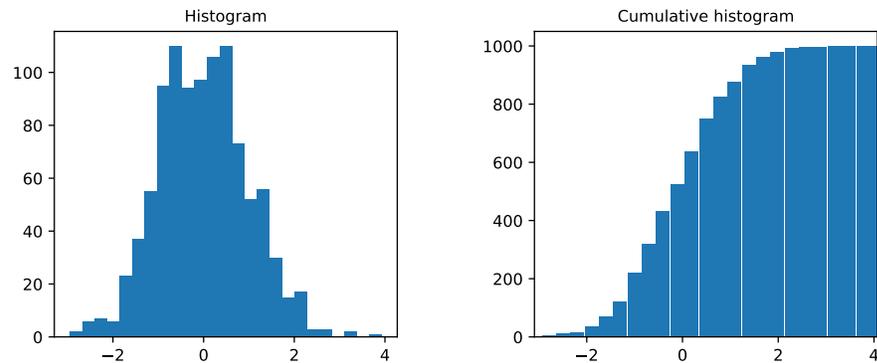

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.cumcount.size,
...
                                   res.cumcount.size)
```

Plot histogram and cumulative histogram

```
>>> fig = plt.figure(figsize=(10, 4))
>>> ax1 = fig.add_subplot(1, 2, 1)
>>> ax2 = fig.add_subplot(1, 2, 2)
>>> ax1.hist(samples, bins=25)
>>> ax1.set_title('Histogram')
>>> ax2.bar(x, res.cumcount, width=res.binsize)
>>> ax2.set_title('Cumulative histogram')
>>> ax2.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

`scipy.stats.itemfreq(a)`

Return a 2-D array of item frequencies.

**Parameters** `a`: (N,) array\_like

**Returns** `itemfreq`: (K, 2)<sup>Input array.</sup> ndarray

A 2-D frequency table. Column 1 contains sorted, unique values from `a`, column 2 contains their respective counts.

**Examples**

```
>>> from scipy import stats
>>> a = np.array([1, 1, 5, 0, 1, 2, 2, 0, 1, 4])
>>> stats.itemfreq(a)
array([[ 0.,  2.],
       [ 1.,  4.],
       [ 2.,  2.],
       [ 4.,  1.],
       [ 5.,  1.]])
>>> np.bincount(a)
array([2, 4, 2, 0, 1, 1])
```

```
>>> stats.itemfreq(a/10.)
array([[ 0. ,  2. ],
       [ 0.1,  4. ],
       [ 0.2,  2. ],
       [ 0.4,  1. ],
       [ 0.5,  1. ]])
```

`scipy.stats.percentileofscore` (*a*, *score*, *kind*='rank')

The percentile rank of a score relative to a list of scores.

A *percentileofscore* of, for example, 80% means that 80% of the scores in *a* are below the given score. In the case of gaps or ties, the exact definition depends on the optional keyword, *kind*.

**Parameters**    **a** : array\_like

Array of scores to which *score* is compared.

**score** : int or float

Score that is compared to the elements in *a*.

**kind** : {'rank', 'weak', 'strict', 'mean'}, optional

This optional parameter specifies the interpretation of the resulting score:

- “**rank**”: *Average percentage ranking of score. In case of multiple matches, average the percentage rankings of all matching scores.*
- “**weak**”: *This kind corresponds to the definition of a cumulative*

*distribution function. A percentileofscore of 80% means that 80% of values are less than or equal to the provided score.*

- “**strict**”: *Similar to “weak”, except that only values that are*

*strictly less than the given score are counted.*

- “**mean**”: *The average of the “weak” and “strict” scores, often used in*

*testing. See*

[http://en.wikipedia.org/wiki/Percentile\\_rank](http://en.wikipedia.org/wiki/Percentile_rank)

**Returns**        **pcos** : float

Percentile-position of score (0-100) relative to *a*.

**See also:**

`numpy.percentile`

**Examples**

Three-quarters of the given values lie below a given score:

```
>>> from scipy import stats
>>> stats.percentileofscore([1, 2, 3, 4], 3)
75.0
```

With multiple matches, note how the scores of the two matches, 0.6 and 0.8 respectively, are averaged:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3)
70.0
```

Only 2/5 values are strictly less than 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='strict')
40.0
```

But 4/5 values are less than or equal to 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='weak')
80.0
```

The average between the weak and the strict scores is

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='mean')
60.0
```

`scipy.stats.scoreatpercentile` (*a*, *per*, *limit*=(), *interpolation\_method*='fraction', *axis*=None)  
 Calculate the score at a given percentile of the input sequence.

For example, the score at *per*=50 is the median. If the desired quantile lies between two data points, we interpolate between them, according to the value of *interpolation*. If the parameter *limit* is provided, it should be a tuple (lower, upper) of two values.

**Parameters**

- a** : array\_like  
A 1-D array of values from which to extract score.
- per** : array\_like  
Percentile(s) at which to extract score. Values should be in range [0,100].
- limit** : tuple, optional  
Tuple of two scalars, the lower and upper limits within which to compute the percentile. Values of *a* outside this (closed) interval will be ignored.
- interpolation\_method** : {'fraction', 'lower', 'higher'}, optional  
This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*
  - fraction:  $i + (j - i) * \text{fraction}$  where *fraction* is the fractional part of the index surrounded by *i* and *j*.
  - lower: *i*.
  - higher: *j*.
- axis** : int, optional  
Axis along which the percentiles are computed. Default is None. If None, compute over the whole array *a*.

**Returns**

- score** : float or ndarray  
Score at percentile(s).

**See also:**

`percentileofscore`, `numpy.percentile`

**Notes**

This function will become obsolete in the future. For Numpy 1.9 and higher, `numpy.percentile` provides all the functionality that `scoreatpercentile` provides. And it's significantly faster. Therefore it's recommended to use `numpy.percentile` for users that have numpy >= 1.9.

**Examples**

```
>>> from scipy import stats
>>> a = np.arange(100)
>>> stats.scoreatpercentile(a, 50)
49.5
```

`scipy.stats.relfreq` (*a*, *numbins*=10, *defaultreallimits*=None, *weights*=None)  
 Return a relative frequency histogram, using the histogram function.

A relative frequency histogram is a mapping of the number of observations in each of the bins relative to the total of observations.

**Parameters**

- a** : array\_like  
Input array.
- numbins** : int, optional  
The number of bins to use for the histogram. Default is 10.
- defaultreallimits** : tuple (lower, upper), optional  
The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.\text{min}() - s, a.\text{max}() + s)$ , where  $s = (1/2)(a.\text{max}() - a.\text{min}()) / (\text{numbins} - 1)$ .
- weights** : array\_like, optional  
The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

**Returns**

- frequency** : ndarray  
Binned values of relative frequency.
- lowerlimit** : float  
Lower real limit
- binsize** : float  
Width of each bin.
- extrapoints** : int  
Extra points.

### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> a = np.array([2, 4, 1, 2, 3, 2])
>>> res = stats.relfreq(a, numbins=4)
>>> res.frequency
array([ 0.16666667, 0.5          , 0.16666667, 0.16666667])
>>> np.sum(res.frequency) # relative frequencies should add up to 1
1.0
```

Create a normal distribution with 1000 random values

```
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate relative frequencies

```
>>> res = stats.relfreq(samples, numbins=25)
```

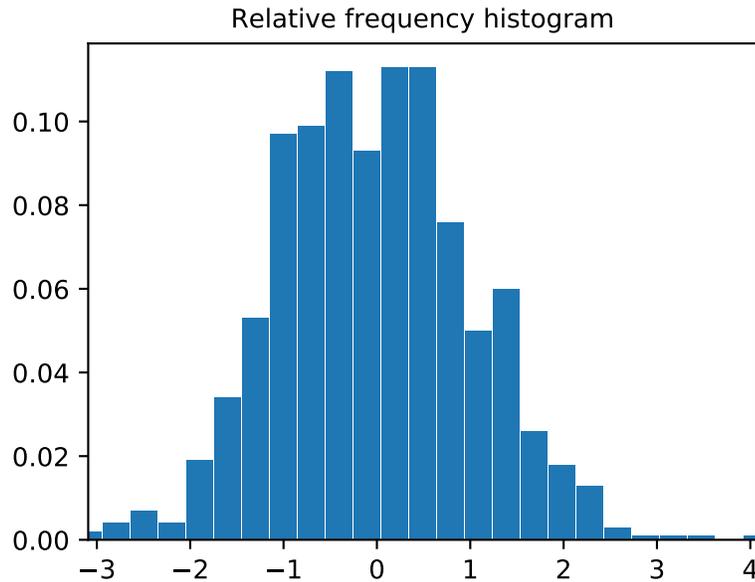

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.frequency.size,
...                                 res.frequency.size)
```

Plot relative frequency histogram

```
>>> fig = plt.figure(figsize=(5, 4))
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.bar(x, res.frequency, width=res.binsize)
>>> ax.set_title('Relative frequency histogram')
>>> ax.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

<code>binned_statistic(x, values[, statistic, ...])</code>	Compute a binned statistic for one or more sets of data.
<code>binned_statistic_2d(x, y, values[, ...])</code>	Compute a bidimensional binned statistic for one or more sets of data.
<code>binned_statistic_dd(sample, values[, ...])</code>	Compute a multidimensional binned statistic for a set of data.

`scipy.stats.binned_statistic(x, values, statistic='mean', bins=10, range=None)`

Compute a binned statistic for one or more sets of data.

This is a generalization of a histogram function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

**Parameters** `x` : (N,) array\_like

A sequence of values to be binned.

**values** : (N,) array\_like or list of (N,) array\_like

The data on which the statistic will be computed. This must be the same shape as `x`, or a set of sequences - each the same shape as `x`. If `values` is a set of sequences, the statistic will be computed on each independently.

**statistic** : string or callable, optional

The statistic to compute (default is 'mean'). The following statistics are available:

- 'mean' : compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- 'median' : compute the median of values for points within each bin. Empty bins will be represented by NaN.
- 'count' : compute the count of points within each bin. This is identical to an unweighted histogram. `values` array is not referenced.
- 'sum' : compute the sum of values for points within each bin. This is identical to a weighted histogram.

- `'min'` : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- `'max'` : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
- `function` : a user-defined function which takes a 1-D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.

**bins** : int or sequence of scalars, optional

If *bins* is an int, it defines the number of equal-width bins in the given range (10 by default). If *bins* is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Values in *x* that are smaller than lowest bin edge are assigned to bin number 0, values beyond the highest bin are assigned to `bins[-1]`. If the bin edges are specified, the number of bins will be,  $(nx = \text{len}(\text{bins})-1)$ .

**range** : (float, float) or [(float, float)], optional

The lower and upper range of the bins. If not provided, range is simply  $(x.\text{min}(), x.\text{max}())$ . Values outside the range are ignored.

**Returns**

**statistic** : array  
The values of the selected statistic in each bin.

**bin\_edges** : array of dtype float

Return the bin edges (`length(statistic)+1`).

**binnumber**: 1-D ndarray of ints

Indices of the bins (corresponding to *bin\_edges*) in which each value of *x* belongs. Same length as *values*. A binnumber of *i* means the corresponding value is between `(bin_edges[i-1], bin_edges[i])`.

**See also:**

`numpy.digitize`, `numpy.histogram`, `binned_statistic_2d`, `binned_statistic_dd`

**Notes**

All but the last (righthand-most) bin is half-open. In other words, if *bins* is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which includes 4.

New in version 0.11.0.

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

First some basic examples:

Create two evenly spaced bins in the range of the given sample, and sum the corresponding values in each of those bins:

```
>>> values = [1.0, 1.0, 2.0, 1.5, 3.0]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
(array([ 4. ,  4.5]), array([ 1.,  4.,  7.]), array([1, 1, 1, 2, 2]))
```

Multiple arrays of values can also be passed. The statistic is calculated on each set independently:

```
>>> values = [[1.0, 1.0, 2.0, 1.5, 3.0], [2.0, 2.0, 4.0, 3.0, 6.0]]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
```

```
(array([[ 4. ,  4.5], [ 8. ,  9. ]]), array([ 1.,  4.,  7.]),
      array([1, 1, 1, 2, 2]))
```

```
>>> stats.binned_statistic([1, 2, 1, 2, 4], np.arange(5), statistic='mean',
...                        bins=3)
(array([ 1.,  2.,  4.]), array([ 1.,  2.,  3.,  4.]),
      array([1, 2, 1, 2, 3]))
```

As a second example, we now generate some random data of sailing boat speed as a function of wind speed, and then determine how fast our boat is for certain wind speeds:

```
>>> windspeed = 8 * np.random.rand(500)
>>> boatspeed = .3 * windspeed**.5 + .2 * np.random.rand(500)
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(windspeed,
...                 boatspeed, statistic='median', bins=[1,2,3,4,5,6,7])
>>> plt.figure()
>>> plt.plot(windspeed, boatspeed, 'b.', label='raw data')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=5,
...           label='binned statistic of data')
>>> plt.legend()
```

Now we can use `binnumber` to select all datapoints with a windspeed below 1:

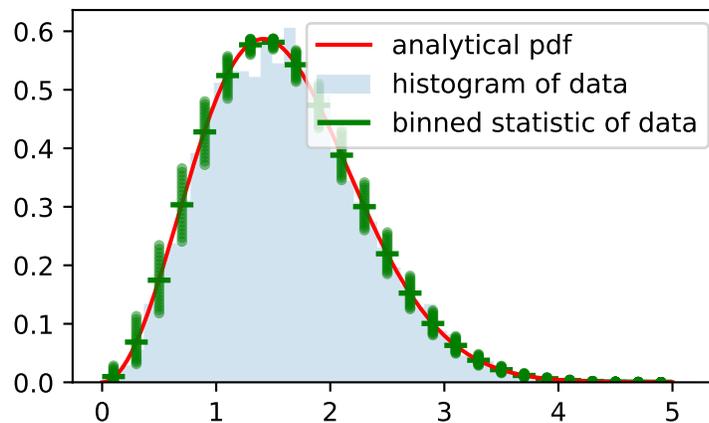

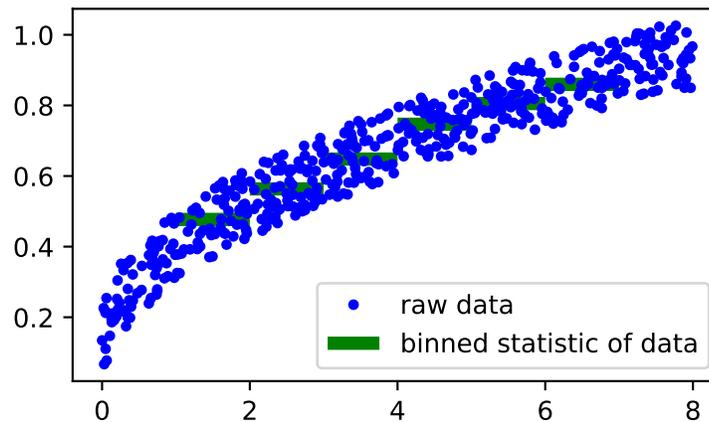

```
>>> low_boatspeed = boatspeed[binnumber == 0]
```

As a final example, we will use `bin_edges` and `binnumber` to make a plot of a distribution that shows the mean and distribution around that mean per bin, on top of a regular histogram and the probability distribution function:

```
>>> x = np.linspace(0, 5, num=500)
>>> x_pdf = stats.maxwell.pdf(x)
>>> samples = stats.maxwell.rvs(size=10000)
```

```
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(x, x_pdf,
...                 statistic='mean', bins=25)
>>> bin_width = (bin_edges[1] - bin_edges[0])
>>> bin_centers = bin_edges[1:] - bin_width/2
```

```
>>> plt.figure()
>>> plt.hist(samples, bins=50, normed=True, histtype='stepfilled',
...         alpha=0.2, label='histogram of data')
>>> plt.plot(x, x_pdf, 'r-', label='analytical pdf')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=2,
...           label='binned statistic of data')
>>> plt.plot((binnumber - 0.5) * bin_width, x_pdf, 'g.', alpha=0.5)
>>> plt.legend(fontsize=10)
>>> plt.show()
```

```
scipy.stats.binned_statistic_2d(x, y, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)
```

Compute a bidimensional binned statistic for one or more sets of data.

This is a generalization of a `histogram2d` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

**Parameters** `x` : (N,) array\_like

A sequence of values to be binned along the first dimension.

`y` : (N,) array\_like

A sequence of values to be binned along the second dimension.

**values** : (N,) array\_like or list of (N,) array\_like

The data on which the statistic will be computed. This must be the same shape as `x`, or a list of sequences - each with the same shape as `x`. If `values` is such a list, the statistic will be computed on each independently.

**statistic** : string or callable, optional

The statistic to compute (default is ‘mean’). The following statistics are available:

- ‘mean’ : compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- ‘median’ : compute the median of values for points within each bin. Empty bins will be represented by NaN.
- ‘count’ : compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
- ‘sum’ : compute the sum of values for points within each bin. This is identical to a weighted histogram.
- ‘min’ : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- ‘max’ : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
- ‘function’ : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.

**bins** : int or [int, int] or array\_like or [array, array], optional

The bin specification:

- the number of bins for the two dimensions ( $nx = ny = bins$ ),
- the number of bins in each dimension ( $nx, ny = bins$ ),
- the bin edges for the two dimensions ( $x\_edge = y\_edge = bins$ ),
- the bin edges in each dimension ( $x\_edge, y\_edge = bins$ ).

If the bin edges are specified, the number of bins will be, ( $nx = len(x\_edge) - 1$ ,  $ny = len(y\_edge) - 1$ ).

**range** : (2,2) array\_like, optional

The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the *bins* parameters): `[[xmin, xmax], [ymin, ymax]]`. All values outside of this range will be considered outliers and not tallied in the histogram.

**expand\_binnumbers** : bool, optional

‘False’ (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. ‘True’: the returned *binnumber* is ‘unraveled’ into a shape (2,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section.

New in version 0.17.0.

**Returns**

**statistic** : (nx, ny) ndarray

The values of the selected statistic in each two-dimensional bin.

**x\_edge** : (nx + 1) ndarray

The bin edges along the first dimension.

**y\_edge** : (ny + 1) ndarray

The bin edges along the second dimension.

**binnumber** : (N,) array of ints or (2,N) ndarray of ints

This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand\_binnumbers* argument. See *Notes* for details.

**See also:**

`numpy.digitize`, `numpy.histogram2d`, `binned_statistic`, `binned_statistic_dd`

**Notes**

Binedges: All but the last (righthand-most) bin is half-open. In other words, if *bins* is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which *includes* 4.

*binnumber*: This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand\_binnumbers* argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If 'True': The returned *binnumber* is a shape (2,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of *i* means the corresponding value is between (D\_edge[i-1], D\_edge[i]), where 'D' is either 'x' or 'y'.

New in version 0.11.0.

### Examples

```
>>> from scipy import stats
```

Calculate the counts with explicit bin-edges:

```
>>> x = [0.1, 0.1, 0.1, 0.6]
>>> y = [2.1, 2.6, 2.1, 2.1]
>>> binx = [0.0, 0.5, 1.0]
>>> biny = [2.0, 2.5, 3.0]
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny])
>>> ret.statistic
array([[ 2.,  1.],
       [ 1.,  0.]])
```

The bin in which each sample is placed is given by the *binnumber* returned parameter. By default, these are the linearized bin indices:

```
>>> ret.binnumber
array([5, 6, 5, 9])
```

The bin indices can also be expanded into separate entries for each dimension using the *expand\_binnumbers* parameter:

```
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny],
...                                 expand_binnumbers=True)
>>> ret.binnumber
array([[1, 1, 1, 2],
       [1, 2, 1, 1]])
```

Which shows that the first three elements belong in the xbin 1, and the fourth into xbin 2; and so on for y.

`scipy.stats.binned_statistic_dd`(*sample*, *values*, *statistic*='mean', *bins*=10, *range*=None, *expand\_binnumbers*=False)

Compute a multidimensional binned statistic for a set of data.

This is a generalization of a histogramdd function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values within each bin.

**Parameters** **sample** : array\_like

Data to histogram passed as a sequence of D arrays of length N, or as an (N,D) array.

**values** : (N,) array\_like or list of (N,) array\_like

The data on which the statistic will be computed. This must be the same shape as *x*, or a list of sequences - each with the same shape as *x*. If *values* is such a list, the statistic will be computed on each independently.

**statistic** : string or callable, optional

The statistic to compute (default is 'mean'). The following statistics are available:

- ‘mean’ : compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- ‘median’ : compute the median of values for points within each bin. Empty bins will be represented by NaN.
- ‘count’ : compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
- ‘sum’ : compute the sum of values for points within each bin. This is identical to a weighted histogram.
- ‘min’ : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- ‘max’ : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
- *function* : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.

**bins** : sequence or int, optional

The bin specification must be in one of the following forms:

- A sequence of arrays describing the bin edges along each dimension.
- The number of bins for each dimension (`nx, ny, ... = bins`).
- The number of bins for all dimensions (`nx = ny = ... = bins`).

**range** : sequence, optional

A sequence of lower and upper bin edges to be used if the edges are not given explicitly in *bins*. Defaults to the minimum and maximum values along each dimension.

**expand\_binnumbers** : bool, optional

‘False’ (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. ‘True’: the returned *binnumber* is ‘unraveled’ into a shape (D,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section of *binned\_statistic\_2d*.

**Returns**

**statistic** : ndarray, shape(nx1, nx2, nx3,...)

The values of the selected statistic in each two-dimensional bin.

**bin\_edges** : list of ndarrays

A list of D arrays describing the (nxi + 1) bin edges for each dimension.

**binnumber** : (N,) array of ints or (D,N) ndarray of ints

This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand\_binnumbers* argument. See *Notes* for details.

**See also:**

`numpy.digitize`, `numpy.histogramdd`, `binned_statistic`, `binned_statistic_2d`

**Notes**

**Binedges:** All but the last (righthand-most) bin is half-open in each dimension. In other words, if *bins* is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which *includes* 4.

**binnumber:** This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand\_binnumbers* argument. If ‘False’ (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If ‘True’: The returned *binnumber* is a shape (D,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of *i* means the corresponding value is between (bin\_edges[D][i-1], bin\_edges[D][i]), for each dimension ‘D’.

New in version 0.11.0.

<code>obrientransform(*args)</code>	Compute the O'Brien transform on input data (any number of arrays).
<code>bayes_mvs(data[, alpha])</code>	Bayesian confidence intervals for the mean, var, and std.
<code>mvsdist(data)</code>	'Frozen' distributions for mean, variance, and standard deviation of data.
<code>sem(a[, axis, ddof, nan_policy])</code>	Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.
<code>zmap(scores, compare[, axis, ddof])</code>	Calculate the relative z-scores.
<code>zscore(a[, axis, ddof])</code>	Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.
<code>iqr(x[, axis, rng, scale, nan_policy, ...])</code>	Compute the interquartile range of the data along the specified axis.

`scipy.stats.obrientransform(*args)`

Compute the O'Brien transform on input data (any number of arrays).

Used to test for homogeneity of variance prior to running one-way stats. Each array in `*args` is one level of a factor. If `f_oneway` is run on the transformed data and found significant, the variances are unequal. From Maxwell and Delaney [R677], p.112.

**Parameters** `args`: tuple of array\_like

**Returns** `obrientransform`: ndarray

Any number of arrays.  
Transformed data for use in an ANOVA. The first dimension of the result corresponds to the sequence of transformed arrays. If the arrays given are all 1-D of the same length, the return value is a 2-D array; otherwise it is a 1-D array of type object, with each element being an ndarray.

### References

[R677]

### Examples

We'll test the following data sets for differences in their variance.

```
>>> x = [10, 11, 13, 9, 7, 12, 12, 9, 10]
>>> y = [13, 21, 5, 10, 8, 14, 10, 12, 7, 15]
```

Apply the O'Brien transform to the data.

```
>>> from scipy.stats import obrientransform
>>> tx, ty = obrientransform(x, y)
```

Use `scipy.stats.f_oneway` to apply a one-way ANOVA test to the transformed data.

```
>>> from scipy.stats import f_oneway
>>> F, p = f_oneway(tx, ty)
>>> p
0.1314139477040335
```

If we require that  $p < 0.05$  for significance, we cannot conclude that the variances are different.

`scipy.stats.bayes_mvs(data, alpha=0.9)`

Bayesian confidence intervals for the mean, var, and std.

**Parameters** **data** : array\_like  
 Input data, if multi-dimensional it is flattened to 1-D by *bayes\_mvs*. Requires 2 or more data points.

**alpha** : float, optional  
 Probability that the returned confidence interval contains the true parameter.

**Returns** **mean\_cntr, var\_cntr, std\_cntr** : tuple  
 The three results are for the mean, variance and standard deviation, respectively. Each result is a tuple of the form:

```
(center, (lower, upper))
```

with *center* the mean of the conditional pdf of the value given the data, and (*lower, upper*) a confidence interval, centered on the median, containing the estimate to a probability *alpha*.

**See also:**

*mvsdist*

**Notes**

Each tuple of mean, variance, and standard deviation estimates represent the (center, (lower, upper)) with center the mean of the conditional pdf of the value given the data and (lower, upper) is a confidence interval centered on the median, containing the estimate to a probability *alpha*.

Converts data to 1-D and assumes all data has the same mean and variance. Uses Jeffrey’s prior for variance and std.

Equivalent to `tuple((x.mean(), x.interval(alpha)) for x in mvsdist(dat))`

**References**

T.E. Oliphant, “A Bayesian perspective on estimating mean, variance, and standard-deviation from data”, <http://scholarsarchive.byu.edu/facpub/278>, 2006.

**Examples**

First a basic example to demonstrate the outputs:

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.bayes_mvs(data)
>>> mean
Mean(statistic=9.0, minmax=(7.1036502226125329, 10.896349777387467))
>>> var
Variance(statistic=10.0, minmax=(3.176724206..., 24.45910382...))
>>> std
Std_dev(statistic=2.9724954732045084, minmax=(1.7823367265645143, 4.
↪9456146050146295))
```

Now we generate some normally distributed random data, and get estimates of mean and standard deviation with 95% confidence intervals for those estimates:

```
>>> n_samples = 100000
>>> data = stats.norm.rvs(size=n_samples)
>>> res_mean, res_var, res_std = stats.bayes_mvs(data, alpha=0.95)
```

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
```

```

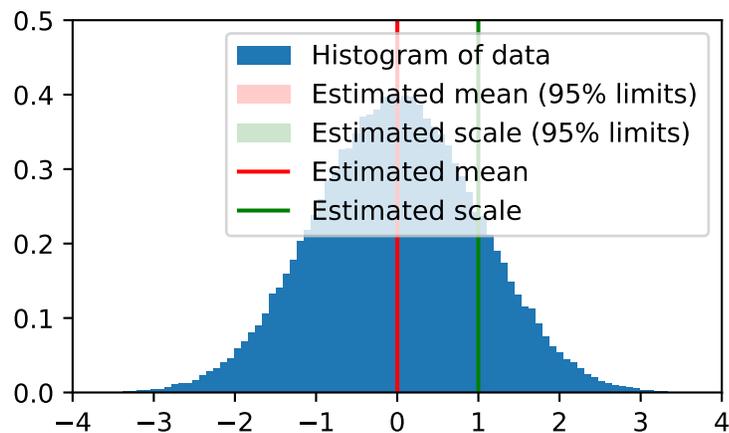

>>> ax.hist(data, bins=100, normed=True, label='Histogram of data')
>>> ax.vlines(res_mean.statistic, 0, 0.5, colors='r', label='Estimated mean')
>>> ax.axvspan(res_mean.minmax[0], res_mean.minmax[1], facecolor='r',
...           alpha=0.2, label=r'Estimated mean (95% limits)')
>>> ax.vlines(res_std.statistic, 0, 0.5, colors='g', label='Estimated scale')
>>> ax.axvspan(res_std.minmax[0], res_std.minmax[1], facecolor='g', alpha=0.2,
...           label=r'Estimated scale (95% limits)')

```

```

>>> ax.legend(fontsize=10)
>>> ax.set_xlim([-4, 4])
>>> ax.set_ylim([0, 0.5])
>>> plt.show()

```

`scipy.stats.mvstdist` (*data*)

‘Frozen’ distributions for mean, variance, and standard deviation of data.

**Parameters** **data** : array\_like

Input array. Converted to 1-D using `ravel`. Requires 2 or more data-points.

**Returns** **mdist** : “frozen” distribution object

Distribution object representing the mean of the data

**vdist** : “frozen” distribution object

Distribution object representing the variance of the data

**sdist** : “frozen” distribution object

Distribution object representing the standard deviation of the data

**See also:**

`bayes_mvs`

**Notes**

The return values from `bayes_mvs(data)` is equivalent to `tuple((x.mean(), x.interval(0.90)) for x in mvstdist(data))`.

In other words, calling `<dist>.mean()` and `<dist>.interval(0.90)` on the three distribution objects returned from this function will give the same results that are returned from `bayes_mvs`.

### References

T.E. Oliphant, “A Bayesian perspective on estimating mean, variance, and standard-deviation from data”, <http://scholarsarchive.byu.edu/facpub/278>, 2006.

### Examples

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.mvstdist(data)
```

We now have frozen distribution objects “mean”, “var” and “std” that we can examine:

```
>>> mean.mean()
9.0
>>> mean.interval(0.95)
(6.6120585482655692, 11.387941451734431)
>>> mean.std()
1.1952286093343936
```

`scipy.stats.sem(a, axis=0, ddof=1, nan_policy='propagate')`

Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.

**Parameters** **a** : array\_like

An array containing the values for which the standard error is returned.

**axis** : int or None, optional

Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**ddof** : int, optional

Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

**nan\_policy** : {‘propagate’, ‘raise’, ‘omit’}, optional

Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns** **s** : ndarray or float

The standard error of the mean in the sample(s), along the input axis.

### Notes

The default value for *ddof* is different to the default (0) used by other *ddof* containing routines, such as `np.std` and `np.nanstd`.

### Examples

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5, 4)
>>> stats.sem(a)
array([ 2.8284,  2.8284,  2.8284,  2.8284])
```

Find standard error across the whole array, using *n* degrees of freedom:

```
>>> stats.sem(a, axis=None, ddof=0)
1.2893796958227628
```

`scipy.stats.zmap` (*scores*, *compare*, *axis=0*, *ddof=0*)

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

**Parameters**

- scores** : array\_like  
The input for which z-scores are calculated.
- compare** : array\_like  
The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as *scores*.
- axis** : int or None, optional  
Axis over which mean and variance of *compare* are calculated. Default is 0. If None, compute over the whole array *scores*.
- ddof** : int, optional  
Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- zscore** : array\_like  
Z-scores, in the same shape as *scores*.

### Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

### Examples

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017,  0.          ,  0.35355339,  0.70710678])
```

`scipy.stats.zscore` (*a*, *axis=0*, *ddof=0*)

Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

**Parameters**

- a** : array\_like  
An array like object containing the sample data.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** : int, optional  
Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- zscore** : array\_like  
The z-scores, standardized by mean and standard deviation of input array *a*.

### Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

### Examples

```
>>> a = np.array([ 0.7972,  0.0767,  0.4383,  0.7866,  0.8091,
...              0.1954,  0.6307,  0.6599,  0.1065,  0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
```

```
array([ 1.1273, -1.247 , -0.0552,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using  $n-1$  degrees of freedom (`ddof=1`) to calculate the standard deviation:

```
>>> b = np.array([[ 0.3148,  0.0478,  0.6243,  0.4608],
...               [ 0.7149,  0.0775,  0.6072,  0.9656],
...               [ 0.6341,  0.1403,  0.9759,  0.4064],
...               [ 0.5918,  0.6948,  0.904 ,  0.3721],
...               [ 0.0921,  0.2481,  0.1188,  0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[ -0.19264823, -1.28415119,  1.07259584,  0.40420358],
       [  0.33048416, -1.37380874,  0.04251374,  1.00081084],
       [  0.26796377, -1.12598418,  1.23283094, -0.37481053],
       [ -0.22095197,  0.24468594,  1.19042819, -1.21416216],
       [ -0.82780366,  1.4457416 , -0.43867764, -0.1792603 ]])
```

`scipy.stats.iqr(x, axis=None, rng=(25, 75), scale='raw', nan_policy='propagate', interpolation='linear', keepdims=False)`

Compute the interquartile range of the data along the specified axis.

The interquartile range (IQR) is the difference between the 75th and 25th percentile of the data. It is a measure of the dispersion similar to standard deviation or variance, but is much more robust against outliers [R651].

The `rng` parameter allows this function to compute other percentile ranges than the actual IQR. For example, setting `rng=(0, 100)` is equivalent to `numpy.ptp`.

The IQR of an empty array is `np.nan`.

New in version 0.18.0.

**Parameters** `x`: array\_like

Input array or object that can be converted to an array.

**axis**: int or sequence of int, optional

Axis along which the range is computed. The default is to compute the IQR for the entire array.

**rng**: Two-element sequence containing floats in range of [0,100] optional

Percentiles over which to compute the range. Each must be between 0 and 100, inclusive. The default is the true IQR: (25, 75). The order of the elements is not important.

**scale**: scalar or str, optional

The numerical value of scale will be divided out of the final result. The following string values are recognized:

‘raw’: No scaling, just return the raw IQR. ‘normal’: Scale by  $2\sqrt{2}erf^{-1}(\frac{1}{2}) \approx 1.349$ .

The default is ‘raw’. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that `out / scale` is a valid operation. The output dimensions depend on the input array, `x`, the `axis` argument, and the `keepdims` flag.

**nan\_policy**: {‘propagate’, ‘raise’, ‘omit’}, optional

Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**interpolation**: {‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}, optional

Specifies the interpolation method to use when the percentile boundaries lie between two data points `i` and `j`:

- **'linear'**  $[i + (j - i) * fraction]$ , where *fraction* is the fractional part of the index surrounded by *i* and *j*.
- **'lower'**: *i*,
- **'higher'**: *j*,
- **'nearest'**: *i* or *j* whichever is nearest.
- **'midpoint'**:  $(i + j) / 2$ .

Default is 'linear'.

**keepdims** : bool, optional

If this is set to *True*, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array *x*.

**Returns**

**iqr** : scalar or ndarray

If *axis=None*, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

**See also:**

`numpy.std`, `numpy.var`

**Notes**

This function is heavily dependent on the version of `numpy` that is installed. Versions greater than 1.11.0b3 are highly recommended, as they include a number of enhancements and fixes to `numpy.percentile` and `numpy.nanpercentile` that affect the operation of this function. The following modifications apply:

**Below 1.10.0** [*nan\_policy* is poorly defined.] The default behavior of `numpy.percentile` is used for 'propagate'. This is a hybrid of 'omit' and 'propagate' that mostly yields a skewed version of 'omit' since NaNs are sorted to the end of the data. A warning is raised if there are NaNs in the data.

**Below 1.9.0:** `numpy.nanpercentile` does not exist.

This means that `numpy.percentile` is used regardless of *nan\_policy* and a warning is issued. See previous item for a description of the behavior.

**Below 1.9.0:** **keepdims and interpolation are not supported.**

The keywords get ignored with a warning if supplied with non-default values. However, multiple axes are still supported.

**References**

**Examples**

```
>>> from scipy.stats import iqr
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> iqr(x)
4.0
>>> iqr(x, axis=0)
array([ 3.5,  2.5,  1.5])
>>> iqr(x, axis=1)
array([ 3.,  1.])
>>> iqr(x, axis=1, keepdims=True)
array([[ 3.],
       [ 1.]])
```

`sigmaclip(a[, low, high])`

Iterative sigma-clipping of array elements.

`trimboth(a, proportiontocut[, axis])`

Slices off a proportion of items from both ends of an array.

Continued on next page

Table 5.294 – continued from previous page

<code>triml(a, proportiontocut[, tail, axis])</code>	Slices off a proportion from ONE end of the passed array distribution.
--	--

`scipy.stats.sigmaclip(a, low=4.0, high=4.0)`

Iterative sigma-clipping of array elements.

The output array contains only those elements of the input array *c* that satisfy the conditions

$$\text{mean}(c) - \text{std}(c) * \text{low} < c < \text{mean}(c) + \text{std}(c) * \text{high}$$

Starting from the full sample, all elements outside the critical range are removed. The iteration continues with a new critical range until no elements are outside the range.

**Parameters**

- a** : array\_like  
Data array, will be raveled if not 1-D.
- low** : float, optional  
Lower bound factor of sigma clipping. Default is 4.
- high** : float, optional  
Upper bound factor of sigma clipping. Default is 4.

**Returns**

- clipped** : ndarray  
Input array with clipped elements removed.
- lower** : float  
Lower threshold value use for clipping.
- upper** : float  
Upper threshold value use for clipping.

**Examples**

```
>>> from scipy.stats import sigmaclip
>>> a = np.concatenate((np.linspace(9.5, 10.5, 31),
...                     np.linspace(0, 20, 5)))
>>> fact = 1.5
>>> c, low, upp = sigmaclip(a, fact, fact)
>>> c
array([ 9.96666667, 10.          , 10.03333333, 10.          ])
>>> c.var(), c.std()
(0.00055555555555555165, 0.023570226039551501)
>>> low, c.mean() - fact*c.std(), c.min()
(9.9646446609406727, 9.9646446609406727, 9.9666666666666668)
>>> upp, c.mean() + fact*c.std(), c.max()
(10.035355339059327, 10.035355339059327, 10.033333333333333)
```

```
>>> a = np.concatenate((np.linspace(9.5, 10.5, 11),
...                     np.linspace(-100, -50, 3)))
>>> c, low, upp = sigmaclip(a, 1.8, 1.8)
>>> (c == np.linspace(9.5, 10.5, 11)).all()
True
```

`scipy.stats.trimboth(a, proportiontocut, axis=0)`

Slices off a proportion of items from both ends of an array.

Slices off the passed proportion of items from both ends of the passed array (i.e., with *proportiontocut* = 0.1, slices leftmost 10% and rightmost 10% of scores). The trimmed values are the lowest and highest ones. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off ‘proportiontocut’).

**Parameters**

- a** : array\_like  
Data to trim.

**proportiontocut** : float  
 Proportion (in range 0-1) of total data set to trim of each end.

**axis** : int or None, optional  
 Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

**Returns** **out** : ndarray  
 Trimmed version of array *a*. The order of the trimmed content is undefined.

**See also:**

`trim_mean`

**Examples**

```
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trimboth(a, 0.1)
>>> b.shape
(16,)
```

`scipy.stats.trim1(a, proportiontocut, tail='right', axis=0)`  
 Slices off a proportion from ONE end of the passed array distribution.

If *proportiontocut* = 0.1, slices off 'leftmost' or 'rightmost' 10% of scores. The lowest or highest values are trimmed (depending on the tail). Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off *proportiontocut* ).

**Parameters** **a** : array\_like  
 Input array

**proportiontocut** : float  
 Fraction to cut off of 'left' or 'right' of distribution

**tail** : {'left', 'right'}, optional  
 Defaults to 'right'.

**axis** : int or None, optional  
 Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

**Returns** **trim1** : ndarray  
 Trimmed version of array *a*. The order of the trimmed content is undefined.

<code>f_oneway(*args)</code>	Performs a 1-way ANOVA.
<code>pearsonr(x, y)</code>	Calculate a Pearson correlation coefficient and the p-value for testing non-correlation.
<code>spearmanr(a[, b, axis, nan_policy])</code>	Calculate a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.
<code>pointbiserialr(x, y)</code>	Calculate a point biserial correlation coefficient and its p-value.
<code>kendalltau(x, y[, initial_lexsort, nan_policy])</code>	Calculate Kendall's tau, a correlation measure for ordinal data.
<code>weightedtau(x, y[, rank, weigher, additive])</code>	Compute a weighted version of Kendall's $\tau$ .
<code>linregress(x[, y])</code>	Calculate a linear least-squares regression for two sets of measurements.
<code>theilslopes(y[, x, alpha])</code>	Computes the Theil-Sen estimator for a set of points (x, y).

`scipy.stats.f_oneway(*args)`  
 Performs a 1-way ANOVA.

The one-way ANOVA tests the null hypothesis that two or more groups have the same population mean. The

test is applied to samples from two or more groups, possibly with differing sizes.

**Parameters** `sample1, sample2, ...` : array\_like  
 The sample measurements for each group.

**Returns** `statistic` : float  
 The computed F-value of the test.

`pvalue` : float  
 The associated p-value from the F-distribution.

**Notes**

The ANOVA test has important assumptions that must be satisfied in order for the associated p-value to be valid.

- 1.The samples are independent.
- 2.Each sample is from a normally distributed population.
- 3.The population standard deviations of the groups are all equal. This property is known as homoscedasticity.

If these assumptions are not true for a given set of data, it may still be possible to use the Kruskal-Wallis H-test (`scipy.stats.kruskal`) although with some loss of power.

The algorithm is from Heiman[2], pp.394-7.

```

`scipy.stats.pearsonr(x, y)`

Calculate a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson’s correlation requires that each dataset be normally distributed, and not necessarily zero-mean. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as x increases, so does y. Negative correlations imply that as x increases, y decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters** `x` : (N,) array\_like  
 Input

**Returns**

- y** : (N,) array\_like
- r** : float      Input
- Pearson's correlation coefficient
- p-value** : float
- 2-tailed p-value

**Notes**

The correlation coefficient is calculated as follows:

$$r_{pb} = \frac{\sum(x - m_x)(y - m_y)}{\sqrt{\sum(x - m_x)^2(y - m_y)^2}}$$

where  $m_x$  is the mean of the vector  $x$  and  $m_y$  is the mean of the vector  $y$ .

**Examples**

```
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pearsonr(a, b)
(0.8660254037844386, 0.011724811003954654)
```

```
>>> stats.pearsonr([1, 2, 3, 4, 5], [5, 6, 7, 8, 7])
(0.83205029433784372, 0.080509573298498519)
```

`scipy.stats.spearmanr` (*a*, *b=None*, *axis=0*, *nan\_policy='propagate'*)

Calculate a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the monotonicity of the relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact monotonic relationship. Positive correlations imply that as  $x$  increases, so does  $y$ . Negative correlations imply that as  $x$  increases,  $y$  decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**    **a, b** : 1D or 2D array\_like, b is optional

One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under `axis`, below. Both arrays need to have the same length in the `axis` dimension.

**axis** : int or None, optional

If `axis=0` (default), then each column represents a variable, with observations in the rows. If `axis=1`, the relationship is transposed: each row represents a variable, while the columns contain observations. If `axis=None`, then both arrays will be raveled.

**nan\_policy** : { 'propagate', 'raise', 'omit' }, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**        **correlation** : float or ndarray (2-D square)

Spearman correlation matrix or correlation coefficient (if only 2 variables are given as parameters. Correlation matrix is square with length equal to total number of variables (columns or rows) in a and b combined.

**pvalue** : float

The two-sided p-value for a hypothesis test whose null hypothesis is that two sets of data are uncorrelated, has same dimension as rho.

**Notes**

Changes in scipy 0.8.0: rewrite to add tie-handling, and axis.

**References**

[R699]

**Examples**

```
>>> from scipy import stats
>>> stats.spearmanr([1,2,3,4,5], [5,6,7,8,7])
(0.82078268166812329, 0.088587005313543798)
>>> np.random.seed(1234321)
>>> x2n = np.random.randn(100, 2)
>>> y2n = np.random.randn(100, 2)
>>> stats.spearmanr(x2n)
(0.059969996999699973, 0.55338590803773591)
>>> stats.spearmanr(x2n[:,0], x2n[:,1])
(0.059969996999699973, 0.55338590803773591)
>>> rho, pval = stats.spearmanr(x2n, y2n)
>>> rho
array([[ 1.          ,  0.05997   ,  0.18569457,  0.06258626],
       [ 0.05997   ,  1.          ,  0.110003  ,  0.02534653],
       [ 0.18569457,  0.110003  ,  1.          ,  0.03488749],
       [ 0.06258626,  0.02534653,  0.03488749,  1.          ]])
>>> pval
array([[ 0.          ,  0.55338591,  0.06435364,  0.53617935],

```

scipy.stats.**pointbiserialr**(x, y)

Calculate a point biserial correlation coefficient and its p-value.

The point biserial correlation is used to measure the relationship between a binary variable, x, and a continuous variable, y. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a deterministic relationship.

This function uses a shortcut formula but produces the same result as `pearsonr`.

**Parameters** `x` : array\_like of bools  
                   Input array.  
`y` : array\_like  
                   Input array.  
**Returns** `correlation` : float  
                   R value  
`pvalue` : float  
                   2-tailed p-value

### Notes

`pointbiserialr` uses a t-test with  $n-1$  degrees of freedom. It is equivalent to `pearsonr`.

The value of the point-biserial correlation can be calculated from:

$$r_{pb} = \frac{\bar{Y}_1 - \bar{Y}_0}{s_y} \sqrt{\frac{N_1 N_2}{N(N-1)}}$$

Where  $Y_0$  and  $Y_1$  are means of the metric observations coded 0 and 1 respectively;  $N_0$  and  $N_1$  are number of observations coded 0 and 1 respectively;  $N$  is the total number of observations and  $s_y$  is the standard deviation of all the metric observations.

A value of  $r_{pb}$  that is significantly different from zero is completely equivalent to a significant difference in means between the two groups. Thus, an independent groups t Test with  $N - 2$  degrees of freedom may be used to test whether  $r_{pb}$  is nonzero. The relation between the t-statistic for comparing two independent groups and  $r_{pb}$  is given by:

$$t = \sqrt{N - 2} \frac{r_{pb}}{\sqrt{1 - r_{pb}^2}}$$

### Examples

```
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pointbiserialr(a, b)
(0.8660254037844386, 0.011724811003954652)
>>> stats.pearsonr(a, b)
(0.86602540378443871, 0.011724811003954626)
>>> np.corrcoef(a, b)
array([[ 1.          ,  0.8660254 ],
       [ 0.8660254 ,  1.          ]])
```

`scipy.stats.kendalltau` ( $x, y, initial\_lexsort=None, nan\_policy='propagate'$ )

Calculate Kendall's tau, a correlation measure for ordinal data.

Kendall's tau is a measure of the correspondence between two rankings. Values close to 1 indicate strong agreement, values close to -1 indicate strong disagreement. This is the 1945 "tau-b" version of Kendall's tau [R655], which can account for ties and which reduces to the 1938 "tau-a" version [R654] in absence of ties.

**Parameters** `x, y` : array\_like  
                   Arrays of rankings, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.

**initial\_lexsort** : bool, optional  
 Unused (deprecated).

**nan\_policy** : { 'propagate', 'raise', 'omit' }, optional  
 Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that if the input contains nan 'omit' delegates to `mstats_basic.kendalltau()`, which has a different implementation.

**Returns**

**correlation** : float  
 The tau statistic.

**pvalue** : float  
 The two-sided p-value for a hypothesis test whose null hypothesis is an absence of association,  $\tau = 0$ .

#### See also:

**spearmanr** Calculates a Spearman rank-order correlation coefficient.

#### theilslopes

Computes the Theil-Sen estimator for a set of points  $(x, y)$ .

#### weightedtau

Computes a weighted version of Kendall's tau.

#### Notes

The definition of Kendall's tau that is used is [R655]:

$$\tau = (P - Q) / \sqrt{((P + Q + T) * (P + Q + U))}$$

where  $P$  is the number of concordant pairs,  $Q$  the number of discordant pairs,  $T$  the number of ties only in  $x$ , and  $U$  the number of ties only in  $y$ . If a tie occurs for the same pair in both  $x$  and  $y$ , it is not added to either  $T$  or  $U$ .

[R654], [R655], [R656], [R657]

#### Examples

```

>>> from scipy import stats
>>> x1 = [12, 2, 1, 12, 2]
>>> x2 = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.kendalltau(x1, x2)
>>> tau
-0.47140452079103173
>>> p_value
0.2827454599327748
    
```

`scipy.stats.weightedtau` ( $x, y, rank=True, weigher=None, additive=True$ )

Compute a weighted version of Kendall's  $\tau$ .

The weighted  $\tau$  is a weighted version of Kendall's  $\tau$  in which exchanges of high weight are more influential than exchanges of low weight. The default parameters compute the additive hyperbolic version of the index,  $\tau_h$ , which has been shown to provide the best balance between important and unimportant elements [R712].

The weighting is defined by means of a rank array, which assigns a nonnegative rank to each element, and a weigher function, which assigns a weight based from the rank to each element. The weight of an exchange is then the sum or the product of the weights of the ranks of the exchanged elements. The default parameters compute  $\tau_h$ : an exchange between elements with rank  $r$  and  $s$  (starting from zero) has weight  $1/(r + 1) + 1/(s + 1)$ .

Specifying a rank array is meaningful only if you have in mind an external criterion of importance. If, as it usually happens, you do not have in mind a specific rank, the weighted  $\tau$  is defined by averaging the values

obtained using the decreasing lexicographical rank by  $(x, y)$  and by  $(y, x)$ . This is the behavior with default parameters.

Note that if you are computing the weighted  $\tau$  on arrays of ranks, rather than of scores (i.e., a larger value implies a lower rank) you must negate the ranks, so that elements of higher rank are associated with a larger value.

**Parameters**

**x, y** : array\_like  
Arrays of scores, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.

**rank** : array\_like of ints or bool, optional  
A nonnegative rank assigned to each element. If it is None, the decreasing lexicographical rank by  $(x, y)$  will be used: elements of higher rank will be those with larger  $x$ -values, using  $y$ -values to break ties (in particular, swapping  $x$  and  $y$  will give a different result). If it is False, the element indices will be used directly as ranks. The default is True, in which case this function returns the average of the values obtained using the decreasing lexicographical rank by  $(x, y)$  and by  $(y, x)$ .

**weigher** : callable, optional  
The weigher function. Must map nonnegative integers (zero representing the most important element) to a nonnegative weight. The default, None, provides hyperbolic weighing, that is, rank  $r$  is mapped to weight  $1/(r+1)$ .

**additive** : bool, optional  
If True, the weight of an exchange is computed by adding the weights of the ranks of the exchanged elements; otherwise, the weights are multiplied. The default is True.

**Returns**

**correlation** : float  
The weighted  $\tau$  correlation index.

**pvalue** : float  
Presently `np.nan`, as the null statistics is unknown (even in the additive hyperbolic case).

See also:

**kendalltau** Calculates Kendall's tau.

**spearmanr** Calculates a Spearman rank-order correlation coefficient.

**theilslopes**

Computes the Theil-Sen estimator for a set of points  $(x, y)$ .

**Notes**

This function uses an  $O(n \log n)$ , mergesort-based algorithm [R712] that is a weighted extension of Knight's algorithm for Kendall's  $\tau$  [R713]. It can compute Shieh's weighted  $\tau$  [R714] between rankings without ties (i.e., permutations) by setting *additive* and *rank* to False, as the definition given in [R712] is a generalization of Shieh's.

NaNs are considered the smallest possible score.

New in version 0.19.0.

**References**

[R712], [R713], [R714]

**Examples**

```
>>> from scipy import stats
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
```

```
>>> tau, p_value = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
>>> p_value
nan
>>> tau, p_value = stats.weightedtau(x, y, additive=False)
>>> tau
-0.62205716951801038
```

NaNs are considered the smallest possible score:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, np.nan]
>>> tau, _ = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
```

This is exactly Kendall's tau:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, _ = stats.weightedtau(x, y, weigher=lambda x: 1)
>>> tau
-0.47140452079103173
```

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> stats.weightedtau(x, y, rank=None)
WeightedTauResult(correlation=-0.4157652301037516, pvalue=nan)
>>> stats.weightedtau(y, x, rank=None)
WeightedTauResult(correlation=-0.71813413296990281, pvalue=nan)
```

`scipy.stats.linregress(x,y=None)`

Calculate a linear least-squares regression for two sets of measurements.

**Parameters** `x, y` : array\_like

Two sets of measurements. Both arrays should have the same length. If only `x` is given (and `y=None`), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension.

**Returns** `slope` : float

slope of the regression line

`intercept` : float

intercept of the regression line

`rvalue` : float

correlation coefficient

`pvalue` : float

two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero, using Wald Test with t-distribution of the test statistic.

`stderr` : float

Standard error of the estimated gradient.

See also:

`scipy.optimize.curve_fit`

Use non-linear least squares to fit a function to data.

`scipy.optimize.leastsq`

Minimize the sum of squares of a set of equations.

**Examples**

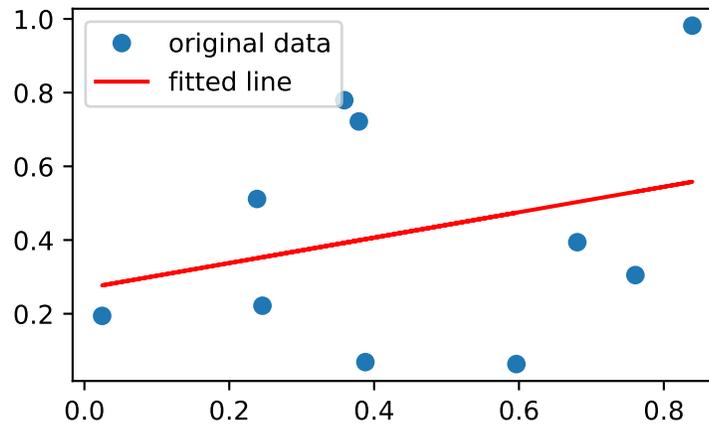

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = np.random.random(10)
>>> y = np.random.random(10)
>>> slope, intercept, r_value, p_value, std_err = stats.linregress(x, y)
```

To get coefficient of determination (`r_squared`)

```
>>> print("r-squared:", r_value**2)
r-squared: 0.080402268539
```

Plot the data along with the fitted line

```
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, intercept + slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

`scipy.stats.theilslopes` (`y`, `x=None`, `alpha=0.95`)

Computes the Theil-Sen estimator for a set of points (`x`, `y`).

`theilslopes` implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

**Parameters** `y`: array\_like

Dependent variable.

`x`: array\_like or None, optional

Independent variable. If None, use `arange(len(y))` instead.

**alpha**: float, optional

Confidence degree between 0 and 1. Default is 95% confidence. Note that `alpha` is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

**Returns** `medslope`: float

Theil slope.

`medintercept`: float

Intercept of the Theil line, as  $\text{median}(y) - \text{medslope} * \text{median}(x)$ .

**lo\_slope** : float  
Lower bound of the confidence interval on *medslope*.

**up\_slope** : float  
Upper bound of the confidence interval on *medslope*.

### Notes

The implementation of *theilslopes* follows [R700]. The intercept is not defined in [R700], and here it is defined as  $\text{median}(y) - \text{medslope} * \text{median}(x)$ , which is given in [R702]. Other definitions of the intercept exist in the literature. A confidence interval for the intercept is not given as this question is not addressed in [R700].

### References

[R700], [R701], [R702]

### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

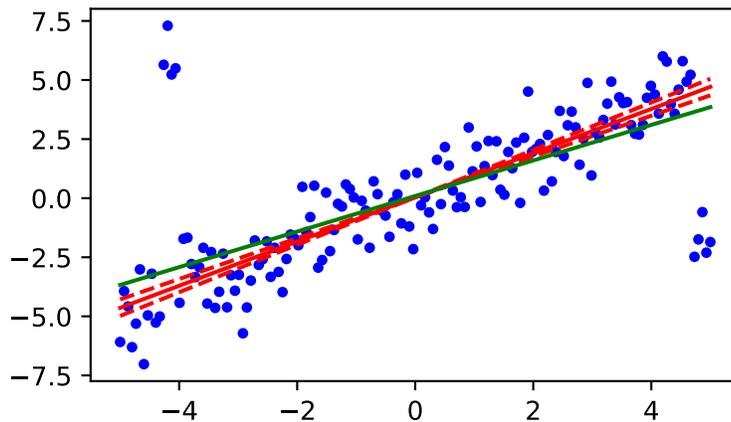

```
>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10 # add outliers
>>> y[-5:] -= 7
```

Compute the slope, intercept and 90% confidence interval. For comparison, also compute the least-squares fit with *linregress*:

```
>>> res = stats.theilslopes(y, x, 0.90)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Theil-Sen regression line is shown in red, with the dashed red lines illustrating the confidence interval of the slope (note that the dashed red lines are not the confidence interval of the regression as the confidence interval of the intercept is not included). The green line shows the least-squares fit for comparison.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.')
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, res[1] + res[2] * x, 'r--')
>>> ax.plot(x, res[1] + res[3] * x, 'r--')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

<code>ttest_1samp(a, popmean[, axis, nan_policy])</code>	Calculate the T-test for the mean of ONE group of scores.
<code>ttest_ind(a, b[, axis, equal_var, nan_policy])</code>	Calculate the T-test for the means of <i>two independent</i> samples of scores.
<code>ttest_ind_from_stats(mean1, std1, nobs1, ...)</code>	T-test for means of two independent samples from descriptive statistics.
<code>ttest_rel(a, b[, axis, nan_policy])</code>	Calculate the T-test on TWO RELATED samples of scores, a and b.
<code>kstest(rvs, cdf[, args, N, alternative, mode])</code>	Perform the Kolmogorov-Smirnov test for goodness of fit.
<code>chisquare(f_obs[, f_exp, ddof, axis])</code>	Calculate a one-way chi square test.
<code>power_divergence(f_obs[, f_exp, ddof, axis, ...])</code>	Cressie-Read power divergence statistic and goodness of fit test.
<code>ks_2samp(data1, data2)</code>	Compute the Kolmogorov-Smirnov statistic on 2 samples.
<code>mannwhitneyu(x, y[, use_continuity, alternative])</code>	Compute the Mann-Whitney rank test on samples x and y.
<code>tiecorrect(rankvals)</code>	Tie correction factor for ties in the Mann-Whitney U and Kruskal-Wallis H tests.
<code>rankdata(a[, method])</code>	Assign ranks to data, dealing with ties appropriately.
<code>ranksums(x, y)</code>	Compute the Wilcoxon rank-sum statistic for two samples.
<code>wilcoxon(x[, y, zero_method, correction])</code>	Calculate the Wilcoxon signed-rank test.
<code>kruskal(*args, **kwargs)</code>	Compute the Kruskal-Wallis H-test for independent samples
<code>friedmanchisquare(*args)</code>	Compute the Friedman test for repeated measurements
<code>combine_pvalues(pvalues[, method, weights])</code>	Methods for combining the p-values of independent tests bearing upon the same hypothesis.
<code>jarque_bera(x)</code>	Perform the Jarque-Bera goodness of fit test on sample data.

`scipy.stats.ttest_1samp(a, popmean, axis=0, nan_policy='propagate')`

Calculate the T-test for the mean of ONE group of scores.

This is a two-sided test for the null hypothesis that the expected value (mean) of a sample of independent observations *a* is equal to the given population mean, *popmean*.

**Parameters**

- a** : array\_like  
sample observation
- popmean** : float or array\_like

expected value in null hypothesis, if `array_like` than it must have the same shape as `a` excluding the axis dimension

**axis** : int or None, optional  
Axis along which to compute test. If None, compute over the whole array `a`.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**statistic** : float or array  
t-statistic

**pvalue** : float or array  
two-tailed p-value

*Examples*

```
>>> from scipy import stats
```

```
>>> np.random.seed(7654567) # fix seed to get the same result
>>> rvs = stats.norm.rvs(loc=5, scale=10, size=(50,2))
```

Test if mean of random sample is equal to true mean, and different mean. We reject the null hypothesis in the second case and don't reject it in the first case.

```
>>> stats.ttest_1samp(rvs, 5.0)
(array([-0.68014479, -0.04323899]), array([ 0.49961383,  0.96568674]))
>>> stats.ttest_1samp(rvs, 0.0)
(array([ 2.77025808,  4.11038784]), array([ 0.00789095,  0.00014999]))
```

Examples using axis and non-scalar dimension for population mean.

```
>>> stats.ttest_1samp(rvs, [5.0, 0.0])
(array([-0.68014479,  4.11038784]), array([ 4.99613833e-01,  1.49986458e-04]))
>>> stats.ttest_1samp(rvs.T, [5.0, 0.0], axis=1)
(array([-0.68014479,  4.11038784]), array([ 4.99613833e-01,  1.49986458e-04]))
>>> stats.ttest_1samp(rvs, [[5.0], [0.0]])
(array([[ -0.68014479, -0.04323899],
        [ 2.77025808,  4.11038784]]), array([[ 4.99613833e-01,  9.65686743e-01],
        [ 7.89094663e-03,  1.49986458e-04]]))
```

`scipy.stats.ttest_ind(a, b, axis=0, equal_var=True, nan_policy='propagate')`

Calculate the T-test for the means of *two independent* samples of scores.

This is a two-sided test for the null hypothesis that 2 independent samples have identical average (expected) values. This test assumes that the populations have identical variances by default.

**Parameters**

**a, b** : array\_like  
The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).

**axis** : int or None, optional  
Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.

**equal\_var** : bool, optional  
If True (default), perform a standard independent 2 sample test that assumes equal population variances [R704]. If False, perform Welch's t-test, which does not assume equal population variance [R705].  
New in version 0.11.0.

	<b>nan_policy</b> : { 'propagate', 'raise', 'omit' }, optional
	Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.
<b>Returns</b>	<b>statistic</b> : float or array
	The calculated t-statistic.
	<b>pvalue</b> : float or array
	The two-tailed p-value.

### Notes

We can use this test, if we observe two independent samples from the same or different population, e.g. exam scores of boys and girls or of two ethnic groups. The test measures whether the average (expected) value differs significantly across samples. If we observe a large p-value, for example larger than 0.05 or 0.1, then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages.

### References

[R704], [R705]

### Examples

```
>>> from scipy import stats
>>> np.random.seed(12345678)
```

Test with sample with identical means:

```
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> stats.ttest_ind(rvs1, rvs2)
(0.26833823296239279, 0.78849443369564776)
>>> stats.ttest_ind(rvs1, rvs2, equal_var = False)
(0.26833823296239279, 0.78849452749500748)
```

*ttest\_ind* underestimates p for unequal variances:

```
>>> rvs3 = stats.norm.rvs(loc=5, scale=20, size=500)
>>> stats.ttest_ind(rvs1, rvs3)
(-0.46580283298287162, 0.64145827413436174)
>>> stats.ttest_ind(rvs1, rvs3, equal_var = False)
(-0.46580283298287162, 0.64149646246569292)
```

When  $n1 \neq n2$ , the equal variance t-statistic is no longer equal to the unequal variance t-statistic:

```
>>> rvs4 = stats.norm.rvs(loc=5, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs4)
(-0.99882539442782481, 0.3182832709103896)
>>> stats.ttest_ind(rvs1, rvs4, equal_var = False)
(-0.69712570584654099, 0.48716927725402048)
```

T-test with different means, variance, and n:

```
>>> rvs5 = stats.norm.rvs(loc=8, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs5)
(-1.4679669854490653, 0.14263895620529152)
>>> stats.ttest_ind(rvs1, rvs5, equal_var = False)
(-0.94365973617132992, 0.34744170334794122)
```

`scipy.stats.ttest_ind_from_stats` (*mean1*, *std1*, *nobs1*, *mean2*, *std2*, *nobs2*, *equal\_var=True*)  
 T-test for means of two independent samples from descriptive statistics.

This is a two-sided test for the null hypothesis that two independent samples have identical average (expected) values.

**Parameters**

- mean1** : array\_like  
The mean(s) of sample 1.
- std1** : array\_like  
The standard deviation(s) of sample 1.
- nobs1** : array\_like  
The number(s) of observations of sample 1.
- mean2** : array\_like  
The mean(s) of sample 2
- std2** : array\_like  
The standard deviations(s) of sample 2.
- nobs2** : array\_like  
The number(s) of observations of sample 2.
- equal\_var** : bool, optional  
If True (default), perform a standard independent 2 sample test that assumes equal population variances [R706]. If False, perform Welch's t-test, which does not assume equal population variance [R707].

**Returns**

- statistic** : float or array  
The calculated t-statistics
- pvalue** : float or array  
The two-tailed p-value.

**See also:**

`scipy.stats.ttest_ind`

**Notes**

New in version 0.16.0.

**References**

[R706], [R707]

**Examples**

Suppose we have the summary data for two samples, as follows:

	Size	Sample Mean	Sample Variance
Sample 1	13	15.0	87.5
Sample 2	11	12.0	39.0

Apply the t-test to this data (with the assumption that the population variances are equal):

```
>>> from scipy.stats import ttest_ind_from_stats
>>> ttest_ind_from_stats(mean1=15.0, std1=np.sqrt(87.5), nobs1=13,
...                      mean2=12.0, std2=np.sqrt(39.0), nobs2=11)
Ttest_indResult(statistic=0.90513580933102689, pvalue=0.37519967975814872)
```

For comparison, here is the data from which those summary statistics were taken. With this data, we can compute the same result using `scipy.stats.ttest_ind`:

```

>>> a = np.array([1, 3, 4, 6, 11, 13, 15, 19, 22, 24, 25, 26, 26])
>>> b = np.array([2, 4, 6, 9, 11, 13, 14, 15, 18, 19, 21])
>>> from scipy.stats import ttest_ind
>>> ttest_ind(a, b)
Ttest_indResult(statistic=0.905135809331027, pvalue=0.37519967975814861)

```

`scipy.stats.ttest_rel(a, b, axis=0, nan_policy='propagate')`

Calculate the T-test on TWO RELATED samples of scores, a and b.

This is a two-sided test for the null hypothesis that 2 related or repeated samples have identical average (expected) values.

**Parameters** **a, b** : array\_like

The arrays must have the same shape.

**axis** : int or None, optional

Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**statistic** : float or array  
t-statistic

**pvalue** : float or array  
two-tailed p-value

### Notes

Examples for the use are scores of the same set of student in different exams, or repeated sampling from the same units. The test measures whether the average score differs significantly across samples (e.g. exams). If we observe a large p-value, for example greater than 0.05 or 0.1 then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages. Small p-values are associated with large t-statistics.

### Examples

```

>>> from scipy import stats
>>> np.random.seed(12345678) # fix random seed to get same numbers

```

```

>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = (stats.norm.rvs(loc=5, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs2)
(0.24101764965300962, 0.80964043445811562)
>>> rvs3 = (stats.norm.rvs(loc=8, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs3)
(-3.9995108708727933, 7.3082402191726459e-005)

```

`scipy.stats.kstest(rvs, cdf, args=(), N=20, alternative='two-sided', mode='approx')`

Perform the Kolmogorov-Smirnov test for goodness of fit.

This performs a test of the distribution  $G(x)$  of an observed random variable against a given distribution  $F(x)$ . Under the null hypothesis the two distributions are identical,  $G(x)=F(x)$ . The alternative hypothesis can be either

‘two-sided’ (default), ‘less’ or ‘greater’. The KS test is only valid for continuous distributions.

**Parameters**

**rvs** : str, array or callable  
 If a string, it should be the name of a distribution in *scipy.stats*. If an array, it should be a 1-D array of observations of random variables. If a callable, it should be a function to generate random variables; it is required to have a keyword argument *size*.

**cdf** : str or callable  
 If a string, it should be the name of a distribution in *scipy.stats*. If *rvs* is a string then *cdf* can be False or the same as *rvs*. If a callable, that callable is used to calculate the cdf.

**args** : tuple, sequence, optional  
 Distribution parameters, used if *rvs* or *cdf* are strings.

**N** : int, optional  
 Sample size if *rvs* is string or callable. Default is 20.

**alternative** : {‘two-sided’, ‘less’, ‘greater’}, optional  
 Defines the alternative hypothesis (see explanation above). Default is ‘two-sided’.

**mode** : ‘approx’ (default) or ‘asympt’, optional  
 Defines the distribution used for calculating the p-value.
 

- ‘approx’ : use approximation to exact distribution of test statistic,
- ‘asympt’ : use asymptotic distribution of test statistic

**Returns**

**statistic** : float  
 KS test statistic, either D, D+ or D-.

**pvalue** : float  
 One-tailed or two-tailed p-value.

**Notes**

In the one-sided test, the alternative is that the empirical cumulative distribution function of the random variable is “less” or “greater” than the cumulative distribution function  $F(x)$  of the hypothesis,  $G(x) \leq F(x)$ , resp.  $G(x) \geq F(x)$ .

**Examples**

```
>>> from scipy import stats
```

```
>>> x = np.linspace(-15, 15, 9)
>>> stats.kstest(x, 'norm')
(0.44435602715924361, 0.038850142705171065)
```

```
>>> np.random.seed(987654321) # set random seed to get the same result
>>> stats.kstest('norm', False, N=100)
(0.058352892479417884, 0.88531190944151261)
```

The above lines are equivalent to:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.norm.rvs(size=100), 'norm')
(0.058352892479417884, 0.88531190944151261)
```

*Test against one-sided alternative hypothesis*

Shift distribution to larger values, so that  $\text{cdf\_dgp}(x) < \text{norm.cdf}(x)$ :

```
>>> np.random.seed(987654321)
>>> x = stats.norm.rvs(loc=0.2, size=100)
>>> stats.kstest(x, 'norm', alternative = 'less')
(0.12464329735846891, 0.040989164077641749)
```

Reject equal distribution against alternative hypothesis: less

```
>>> stats.kstest(x, 'norm', alternative = 'greater')
(0.0072115233216311081, 0.98531158590396395)
```

Don't reject equal distribution against alternative hypothesis: greater

```
>>> stats.kstest(x, 'norm', mode='asympt')
(0.12464329735846891, 0.08944488871182088)
```

*Testing t distributed random variables against normal distribution*

With 100 degrees of freedom the t distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(100, size=100), 'norm')
(0.072018929165471257, 0.67630062862479168)
```

With 3 degrees of freedom the t distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(3, size=100), 'norm')
(0.131016895759829, 0.058826222555312224)
```

`scipy.stats.chisquare` (*f\_obs*, *f\_exp*=None, *ddof*=0, *axis*=0)

Calculate a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

**Parameters**

- f\_obs** : array\_like  
Observed frequencies in each category.
- f\_exp** : array\_like, optional  
Expected frequencies in each category. By default the categories are assumed to be equally likely.
- ddof** : int, optional  
“Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where  $k$  is the number of observed frequencies. The default value of *ddof* is 0.
- axis** : int or None, optional  
The axis of the broadcast result of *f\_obs* and *f\_exp* along which to apply the test. If axis is None, all values in *f\_obs* are treated as a single data set. Default is 0.

**Returns**

- chisq** : float or ndarray  
The chi-squared test statistic. The value is a float if *axis* is None or *f\_obs* and *f\_exp* are 1-D.
- p** : float or ndarray  
The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

**See also:**

`power_divergence`, `mstats.chisquare`

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom,  $k-1$ , are for the case when no parameters of the distribution are estimated. If  $p$  parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are  $k-1-p$ . If the parameters are estimated in a different way, then the dof can be between  $k-1-p$  and  $k-1$ . However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

**References**

[R621], [R622]

**Examples**

When just `f_obs` is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With `f_exp` the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When `f_obs` is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2.          ,  6.66666667]), array([ 0.84914504,  0.24663415]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

`ddof` is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with `ddof`.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

$f_{obs}$  and  $f_{exp}$  are also broadcast. In the following,  $f_{obs}$  has shape (6,) and  $f_{exp}$  has shape (2, 6), so the result of broadcasting  $f_{obs}$  and  $f_{exp}$  has shape (2, 6). To compute the desired chi-squared statistics, we use `axis=1`:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
...           f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...           axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

`scipy.stats.power_divergence` ( $f_{obs}$ ,  $f_{exp}=None$ ,  $ddof=0$ ,  $axis=0$ ,  $lambda_=None$ )

Cressie-Read power divergence statistic and goodness of fit test.

This function tests the null hypothesis that the categorical data has the given frequencies, using the Cressie-Read power divergence statistic.

**Parameters** `f_obs` : array\_like

Observed frequencies in each category.

`f_exp` : array\_like, optional

Expected frequencies in each category. By default the categories are assumed to be equally likely.

`ddof` : int, optional

“Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - ddof$  degrees of freedom, where  $k$  is the number of observed frequencies. The default value of `ddof` is 0.

`axis` : int or None, optional

The axis of the broadcast result of  $f_{obs}$  and  $f_{exp}$  along which to apply the test. If axis is None, all values in  $f_{obs}$  are treated as a single data set. Default is 0.

`lambda_` : float or str, optional

`lambda_` gives the power in the Cressie-Read power divergence statistic. The default is 1. For convenience, `lambda_` may be assigned one of the following strings, in which case the corresponding numerical value is used:

String	Value	Description
"pearson"	1	Pearson's chi-squared <code>statistic</code> . In this case, the function <code>is chisquare`</code> is equivalent to <code>stats.log-likelihood`</code> .
"log-likelihood"	0	Log-likelihood ratio. Also known as the G-test [R684].
"freeman-tukey"	-1/2	Freeman-Tukey statistic.
"mod-log-likelihood"	-1	Modified log-likelihood <code>ratio</code> .
"neyman"	-2	Neyman's statistic.
"cressie-read"	2/3	The power recommended in [R686].

**Returns** `statistic` : float or ndarray

The Cressie-Read power divergence test statistic. The value is a float if `axis` is None or if  $f_{obs}$  and  $f_{exp}$  are 1-D.

`pvalue` : float or ndarray

The p-value of the test. The value is a float if `ddof` and the return value `stat` are scalars.

**See also:**

*chisquare*

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

When *lambda\_* is less than zero, the formula for the statistic involves dividing by *f\_obs*, so a warning or error may be generated if any value in *f\_obs* is 0.

Similarly, a warning or error may be generated if any value in *f\_exp* is zero when *lambda\_*  $\geq$  0.

The default degrees of freedom, *k*-1, are for the case when no parameters of the distribution are estimated. If *p* parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are *k*-1-*p*. If the parameters are estimated in a different way, then the dof can be between *k*-1-*p* and *k*-1. However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

This function handles masked arrays. If an element of *f\_obs* or *f\_exp* is masked, then data at that position is ignored, and does not count towards the size of the data set.

New in version 0.13.0.

**References**

[R682], [R683], [R684], [R685], [R686]

**Examples**

(See *chisquare* for more examples.)

When just *f\_obs* is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies. Here we perform a G-test (i.e. use the log-likelihood ratio statistic):

```
>>> from scipy.stats import power_divergence
>>> power_divergence([16, 18, 16, 14, 12, 12], lambda_='log-likelihood')
(2.006573162632538, 0.84823476779463769)
```

The expected frequencies can be given with the *f\_exp* argument:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[16, 16, 16, 16, 16, 8],
...                  lambda_='log-likelihood')
(3.3281031458963746, 0.6495419288047497)
```

When *f\_obs* is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
>>> power_divergence(obs, lambda_="log-likelihood")
(array([ 2.00657316,  6.77634498]), array([ 0.84823477,  0.23781225]))
```

By setting *axis=None*, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> power_divergence(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> power_divergence(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

*ddof* is the change to make to the default degrees of freedom.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the test statistic with *ddof*.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

*f\_obs* and *f\_exp* are also broadcast. In the following, *f\_obs* has shape (6,) and *f\_exp* has shape (2, 6), so the result of broadcasting *f\_obs* and *f\_exp* has shape (2, 6). To compute the desired chi-squared statistics, we must use `axis=1`:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[[16, 16, 16, 16, 16, 8],
...                         [8, 20, 20, 16, 12, 12]],
...                  axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

`scipy.stats.ks_2samp` (*data1*, *data2*)

Compute the Kolmogorov-Smirnov statistic on 2 samples.

This is a two-sided test for the null hypothesis that 2 independent samples are drawn from the same continuous distribution.

<b>Parameters</b>	<b>data1, data2</b> : sequence of 1-D ndarrays
	two arrays of sample observations assumed to be drawn from a continuous distribution, sample sizes can be different
<b>Returns</b>	<b>statistic</b> : float
	KS statistic
	<b>pvalue</b> : float
	two-tailed p-value

### Notes

This tests whether 2 samples are drawn from the same distribution. Note that, like in the case of the one-sample K-S test, the distribution is assumed to be continuous.

This is the two-sided test, one-sided tests are not implemented. The test uses the two-sided asymptotic Kolmogorov-Smirnov distribution.

If the K-S statistic is small or the p-value is high, then we cannot reject the hypothesis that the distributions of the two samples are the same.

### Examples

```
>>> from scipy import stats
>>> np.random.seed(12345678) #fix random seed to get the same result
>>> n1 = 200 # size of first sample
>>> n2 = 300 # size of second sample
```

For a different distribution, we can reject the null hypothesis since the pvalue is below 1%:

```
>>> rvs1 = stats.norm.rvs(size=n1, loc=0., scale=1)
>>> rvs2 = stats.norm.rvs(size=n2, loc=0.5, scale=1.5)
>>> stats.ks_2samp(rvs1, rvs2)
(0.20833333333333337, 4.6674975515806989e-005)
```

For a slightly different distribution, we cannot reject the null hypothesis at a 10% or lower alpha since the p-value at 0.144 is higher than 10%

```
>>> rvs3 = stats.norm.rvs(size=n2, loc=0.01, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs3)
(0.10333333333333333, 0.14498781825751686)
```

For an identical distribution, we cannot reject the null hypothesis since the p-value is high, 41%:

```
>>> rvs4 = stats.norm.rvs(size=n2, loc=0.0, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs4)
(0.079999999999999996, 0.41126949729859719)
```

`scipy.stats.mannwhitneyu(x, y, use_continuity=True, alternative=None)`

Compute the Mann-Whitney rank test on samples x and y.

**Parameters**

- x, y** : array\_like  
Array of samples, should be one-dimensional.
- use\_continuity** : bool, optional  
Whether a continuity correction (1/2.) should be taken into account. Default is True.
- alternative** : None (deprecated), 'less', 'two-sided', or 'greater'  
Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults to None, which results in a p-value half the size of the 'two-sided' p-value and a different U statistic. The default behavior is not the same as using 'less' or 'greater': it only exists for backward compatibility and is deprecated.

**Returns**

- statistic** : float  
The Mann-Whitney U statistic, equal to  $\min(U \text{ for } x, U \text{ for } y)$  if *alternative* is equal to None (deprecated; exists for backward compatibility), and U for y otherwise.
- pvalue** : float  
p-value assuming an asymptotic normal distribution. One-sided or two-sided, depending on the choice of *alternative*.

**Notes**

Use only when the number of observation in each sample is > 20 and you have 2 independent samples of ranks. Mann-Whitney U is significant if the u-obtained is LESS THAN or equal to the critical value of U.

This test corrects for ties and by default uses a continuity correction.

**References**

[R665], [R666]

`scipy.stats.tiecorrect(rankvals)`

Tie correction factor for ties in the Mann-Whitney U and Kruskal-Wallis H tests.

**Parameters**

- rankvals** : array\_like  
A 1-D sequence of ranks. Typically this will be the array returned by `stats.rankdata`.

**Returns**

- factor** : float  
Correction factor for U or H.

**See also:**

**rankdata** Assign ranks to the data  
**mannwhitneyu** Mann-Whitney rank test

**kruskal** Kruskal-Wallis H test

### References

[R703]

### Examples

```
>>> from scipy.stats import tiecorrect, rankdata
>>> tiecorrect([1, 2.5, 2.5, 4])
0.9
>>> ranks = rankdata([1, 3, 2, 4, 5, 7, 2, 8, 4])
>>> ranks
array([ 1. ,  4. ,  2.5,  5.5,  7. ,  8. ,  2.5,  9. ,  5.5])
>>> tiecorrect(ranks)
0.9833333333333333
```

`scipy.stats.rankdata` (*a*, *method*='average')

Assign ranks to data, dealing with ties appropriately.

Ranks begin at 1. The *method* argument controls how ranks are assigned to equal values. See [R690] for further discussion of ranking methods.

**Parameters** **a** : array\_like

The array of values to be ranked. The array is first flattened.

**method** : str, optional

The method used to assign ranks to tied elements. The options are 'average', 'min', 'max', 'dense' and 'ordinal'.

**'average'**: The average of the ranks that would have been assigned to all the tied values is assigned to each value.

**'min'**: The minimum of the ranks that would have been assigned to all the tied values is assigned to each value. (This is also referred to as "competition" ranking.)

**'max'**: The maximum of the ranks that would have been assigned to all the tied values is assigned to each value.

**'dense'**: Like 'min', but the rank of the next highest element is assigned the rank immediately after those assigned to the tied elements.

**'ordinal'**: All values are given a distinct rank, corresponding to the order that the values occur in *a*.

**Returns** **ranks** : ndarray

The default is 'average'.

An array of length equal to the size of *a*, containing rank scores.

### Examples

```
>>> from scipy.stats import rankdata
>>> rankdata([0, 2, 3, 2])
array([ 1. ,  2.5,  4. ,  2.5])
>>> rankdata([0, 2, 3, 2], method='min')
array([ 1,  2,  4,  2])
>>> rankdata([0, 2, 3, 2], method='max')
array([ 1,  3,  4,  3])
>>> rankdata([0, 2, 3, 2], method='dense')
array([ 1,  2,  3,  2])
>>> rankdata([0, 2, 3, 2], method='ordinal')
array([ 1,  2,  4,  3])
```

`scipy.stats.ranksums(x, y)`

Compute the Wilcoxon rank-sum statistic for two samples.

The Wilcoxon rank-sum test tests the null hypothesis that two sets of measurements are drawn from the same distribution. The alternative hypothesis is that values in one sample are more likely to be larger than the values in the other sample.

This test should be used to compare two samples from continuous distributions. It does not handle ties between measurements in  $x$  and  $y$ . For tie-handling and an optional continuity correction see `scipy.stats.mannwhitneyu`.

**Parameters** `x,y` : array\_like  
 The data from the two samples

**Returns** `statistic` : float  
 The test statistic under the large-sample approximation that the rank sum statistic is normally distributed

`pvalue` : float  
 The two-sided p-value of the test

**References**

[R691]

`scipy.stats.wilcoxon(x, y=None, zero_method='wilcox', correction=False)`

Calculate the Wilcoxon signed-rank test.

The Wilcoxon signed-rank test tests the null hypothesis that two related paired samples come from the same distribution. In particular, it tests whether the distribution of the differences  $x - y$  is symmetric about zero. It is a non-parametric version of the paired T-test.

**Parameters** `x` : array\_like  
 The first set of measurements.

`y` : array\_like, optional  
 The second set of measurements. If  $y$  is not given, then the  $x$  array is considered to be the differences between the two sets of measurements.

**zero\_method** : string, {"pratt", "wilcox", "zsplit"}, optional  
 "pratt": Pratt treatment: includes zero-differences in the ranking process (more conservative)  
 "wilcox": Wilcox treatment: discards all zero-differences  
 "zsplit": Zero rank split: just like Pratt, but splitting the zero rank between positive and negative ones

**correction** : bool, optional  
 If True, apply continuity correction by adjusting the Wilcoxon rank statistic by 0.5 towards the mean value when computing the z-statistic. Default is False.

**Returns** `statistic` : float  
 The sum of the ranks of the differences above or below zero, whichever is smaller.

`pvalue` : float  
 The two-sided p-value for the test.

**Notes**

Because the normal approximation is used for the calculations, the samples used should be large. A typical rule is to require that  $n > 20$ .

**References**

[R715]

`scipy.stats.kruskal(*args, **kwargs)`

Compute the Kruskal-Wallis H-test for independent samples

The Kruskal-Wallis H-test tests the null hypothesis that the population median of all of the groups are equal. It is a non-parametric version of ANOVA. The test works on 2 or more independent samples, which may have different sizes. Note that rejecting the null hypothesis does not indicate which of the groups differs. Post-hoc comparisons between groups are required to determine which groups are different.

<b>Parameters</b>	<b>sample1, sample2, ...</b> : array_like Two or more arrays with the sample measurements can be given as arguments.
	<b>nan_policy</b> : {'propagate', 'raise', 'omit'}, optional Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.
<b>Returns</b>	<b>statistic</b> : float The Kruskal-Wallis H statistic, corrected for ties
	<b>pvalue</b> : float The p-value for the test using the assumption that H has a chi square distribution

**See also:**

**f\_oneway** 1-way ANOVA

**mannwhitneyu**

Mann-Whitney rank test on two samples.

**friedmanchisquare**

Friedman test for repeated measurements

**Notes**

Due to the assumption that H has a chi square distribution, the number of samples in each group must not be too small. A typical rule is that each sample must have at least 5 measurements.

**References**

[R658], [R659]

**Examples**

```
>>> from scipy import stats
>>> x = [1, 3, 5, 7, 9]
>>> y = [2, 4, 6, 8, 10]
>>> stats.kruskal(x, y)
KruskalResult(statistic=0.27272727272727337, pvalue=0.60150813444058948)
```

```
>>> x = [1, 1, 1]
>>> y = [2, 2, 2]
>>> z = [2, 2]
>>> stats.kruskal(x, y, z)
KruskalResult(statistic=7.0, pvalue=0.030197383422318501)
```

`scipy.stats.friedmanchisquare(*args)`

Compute the Friedman test for repeated measurements

The Friedman test tests the null hypothesis that repeated measurements of the same individuals have the same distribution. It is often used to test for consistency among measurements obtained in different ways. For example, if two measurement techniques are used on the same set of individuals, the Friedman test can be used to determine if the two measurement techniques are consistent.

**Parameters** **measurements1, measurements2, measurements3...** : array\_like  
 Arrays of measurements. All of the arrays must have the same number of elements. At least 3 sets of measurements must be given.

**Returns** **statistic** : float  
 the test statistic, correcting for ties

**pvalue** : float  
 the associated p-value assuming that the test statistic has a chi squared distribution

**Notes**

Due to the assumption that the test statistic has a chi squared distribution, the p-value is only reliable for  $n > 10$  and more than 6 repeated measurements.

**References**

[R641]

`scipy.stats.combine_pvalues` (*pvalues*, *method='fisher'*, *weights=None*)

Methods for combining the p-values of independent tests bearing upon the same hypothesis.

**Parameters** **pvalues** : array\_like, 1-D  
 Array of p-values assumed to come from independent tests.

**method** : {'fisher', 'stouffer'}, optional  
 Name of method to use to combine p-values. The following methods are available:

- “fisher”: Fisher’s method (Fisher’s combined probability test), the default.
- stouffer: Stouffer’s Z-score method.

**weights** : array\_like, 1-D, optional  
 Optional array of weights used only for Stouffer’s Z-score method.

**Returns** **statistic**: float  
 The statistic calculated by the specified method: - “fisher”: The chi-squared statistic - “stouffer”: The Z-score

**pval**: float  
 The combined p-value.

**Notes**

Fisher’s method (also known as Fisher’s combined probability test) [R623] uses a chi-squared statistic to compute a combined p-value. The closely related Stouffer’s Z-score method [R624] uses Z-scores rather than p-values. The advantage of Stouffer’s method is that it is straightforward to introduce weights, which can make Stouffer’s method more powerful than Fisher’s method when the p-values are from studies of different size [R625] [R626].

Fisher’s method may be extended to combine p-values from dependent tests [R627]. Extensions such as Brown’s method and Kost’s method are not currently implemented.

New in version 0.15.0.

`scipy.stats.jarque_bera` (*x*)

Perform the Jarque-Bera goodness of fit test on sample data.

The Jarque-Bera test tests whether the sample data has the skewness and kurtosis matching a normal distribution.

Note that this test only works for a large enough number of data samples (>2000) as the test statistic asymptotically has a Chi-squared distribution with 2 degrees of freedom.

**Parameters** `x` : array\_like  
**Returns** `jb_value` : float Observations of a random variable.  
The test statistic.  
`p` : float  
The p-value for the hypothesis test.

**References**

[R653]

**Examples**

```
>>> from scipy import stats
>>> np.random.seed(987654321)
>>> x = np.random.normal(0, 1, 100000)
>>> y = np.random.rayleigh(1, 100000)
>>> stats.jarque_bera(x)
(4.7165707989581342, 0.09458225503041906)
>>> stats.jarque_bera(y)
(6713.7098548143422, 0.0)
```

`scipy.stats.ansari(x, y)`

Perform the Ansari-Bradley test for equal scale parameters

The Ansari-Bradley test is a non-parametric test for the equality of the scale parameter of the distributions from which two samples were drawn.

**Parameters** `x, y` : array\_like  
**Returns** `statistic` : float arrays of sample data  
The Ansari-Bradley test statistic  
`pvalue` : float  
The p-value of the hypothesis test

**See also:**

**fligner** A non-parametric test for the equality of k variances  
**mood** A non-parametric test for the equality of two scale parameters

**Notes**

The p-value given is exact when the sample sizes are both less than 55 and there are no ties, otherwise a normal approximation for the p-value is used.

[R608]

`scipy.stats.bartlett` (\*args)

Perform Bartlett's test for equal variances

Bartlett's test tests the null hypothesis that all input samples are from populations with equal variances. For samples from significantly non-normal populations, Levene's test `levene` is more robust.

**Parameters** `sample1, sample2,...` : array\_like  
arrays of sample data. May be different lengths.

**Returns** `statistic` : float  
The test statistic.

`pvalue` : float  
The p-value of the test.

### See also:

**fligner** A non-parametric test for the equality of k variances  
**levene** A robust parametric test for equality of k variances

### Notes

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [R612].

### References

[R610], [R611], [R612], [R613]

`scipy.stats.levene` (\*args, \*\*kwds)

Perform Levene test for equal variances.

The Levene test tests the null hypothesis that all input samples are from populations with equal variances. Levene's test is an alternative to Bartlett's test `bartlett` in the case where there are significant deviations from normality.

**Parameters** `sample1, sample2, ...` : array\_like  
The sample data, possibly with different lengths

`center` : {'mean', 'median', 'trimmed'}, optional  
Which function of the data to use in the test. The default is 'median'.

`proportiontocut` : float, optional  
When `center` is 'trimmed', this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`.) Default is 0.05.

**Returns** `statistic` : float  
The test statistic.

`pvalue` : float  
The p-value for the test.

### Notes

Three variations of Levene's test are possible. The possibilities and their recommended usages are:

- 'median' : Recommended for skewed (non-normal) distributions>
- 'mean' : Recommended for symmetric, moderate-tailed distributions.
- 'trimmed' : Recommended for heavy-tailed distributions.

[R662], [R663], [R664]

`scipy.stats.shapiro(x)`

Perform the Shapiro-Wilk test for normality.

The Shapiro-Wilk test tests the null hypothesis that the data was drawn from a normal distribution.

**Parameters** `x` : array\_like  
 Array of sample data.

**Returns** `W` : float  
 The test statistic.

`p-value` : float  
 The p-value for the hypothesis test.

**See also:**

**anderson** The Anderson-Darling test for normality

**kstest** The Kolmogorov-Smirnov test for goodness of fit.

**Notes**

The algorithm used is described in [R695] but censoring parameters as described are not implemented. For  $N > 5000$  the  $W$  test statistic is accurate but the p-value may not be.

The chance of rejecting the null hypothesis when it is true is close to 5% regardless of sample size.

**Examples**

```
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = stats.norm.rvs(loc=5, scale=3, size=100)
>>> stats.shapiro(x)
(0.9772805571556091, 0.08144091814756393)
```

`scipy.stats.anderson(x, dist='norm')`

Anderson-Darling test for data coming from a particular distribution

The Anderson-Darling test is a modification of the Kolmogorov-Smirnov test `kstest` for the null hypothesis that a sample is drawn from a population that follows a particular distribution. For the Anderson-Darling test, the critical values depend on which distribution is being tested against. This function works for normal, exponential, logistic, or Gumbel (Extreme Value Type I) distributions.

**Parameters** `x` : array\_like  
 array of sample data

**dist** : {'norm', 'expon', 'logistic', 'gumbel', 'gumbel\_l', 'gumbel\_r', 'extreme1'}, optional the type of distribution to test against. The default is 'norm' and 'extreme1', 'gumbel\_l' and 'gumbel' are synonyms.

**Returns** **statistic** : float  
 The Anderson-Darling test statistic

**critical\_values** : list  
 The critical values for this distribution

**significance\_level** : list  
 The significance levels for the corresponding critical values in percents. The function returns critical values for a differing set of significance levels depending on the distribution that is being tested against.

*Notes*

Critical values provided are for the following significance levels:

**normal/exponential**

15%, 10%, 5%, 2.5%, 1%

**logistic** 25%, 10%, 5%, 2.5%, 1%, 0.5%

**Gumbel** 25%, 10%, 5%, 2.5%, 1%

If  $A_2$  is larger than these critical values then for the corresponding significance level, the null hypothesis that the data come from the chosen distribution can be rejected.

*References*

[R601], [R602], [R603], [R604], [R605], [R606]

`scipy.stats.anderson_ksamp` (*samples*, *midrank=True*)

The Anderson-Darling test for k-samples.

The k-sample Anderson-Darling test is a modification of the one-sample Anderson-Darling test. It tests the null hypothesis that k-samples are drawn from the same population without having to specify the distribution function of that population. The critical values depend on the number of samples.

<b>Parameters</b>	<p><b>samples</b> : sequence of 1-D array_like Array of sample data in arrays.</p> <p><b>midrank</b> : bool, optional Type of Anderson-Darling test which is computed. Default (True) is the midrank test applicable to continuous and discrete populations. If False, the right side empirical distribution is used.</p>
<b>Returns</b>	<p><b>statistic</b> : float Normalized k-sample Anderson-Darling test statistic.</p> <p><b>critical_values</b> : array The critical values for significance levels 25%, 10%, 5%, 2.5%, 1%.</p> <p><b>significance_level</b> : float An approximate significance level at which the null hypothesis for the provided samples can be rejected.</p>
<b>Raises</b>	<p><b>ValueError</b> If less than 2 samples are provided, a sample is empty, or no distinct observations are in the samples.</p>

**See also:**

**ks\_2samp** 2 sample Kolmogorov-Smirnov test

**anderson** 1 sample Anderson-Darling test

*Notes*

[R607] Defines three versions of the k-sample Anderson-Darling test: one for continuous distributions and two for discrete distributions, in which ties between samples may occur. The default of this routine is to compute the version based on the midrank empirical distribution function. This test is applicable to continuous and discrete data. If midrank is set to False, the right side empirical distribution is used for a test for discrete data. According to [R607], the two discrete test statistics differ only slightly if a few collisions due to round-off errors occur in the test not adjusted for ties between samples.

New in version 0.14.0.

*References*

[R607]

### Examples

```
>>> from scipy import stats
>>> np.random.seed(314159)
```

The null hypothesis that the two random samples come from the same distribution can be rejected at the 5% level because the returned test value is greater than the critical value for 5% (1.961) but not at the 2.5% level. The interpolation gives an approximate significance level of 3.1%:

```
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(loc=0.5, size=30)])
(2.4615796189876105,
 array([ 0.325,  1.226,  1.961,  2.718,  3.752]),
 0.03134990135800783)
```

The null hypothesis cannot be rejected for three samples from an identical distribution. The approximate p-value (87%) has to be computed by extrapolation and may not be very accurate:

```
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(size=30), np.random.normal(size=20)])
(-0.73091722665244196,
 array([ 0.44925884,  1.3052767 ,  1.9434184 ,  2.57696569,  3.41634856]),
 0.8789283903979661)
```

`scipy.stats.binom_test(x, n=None, p=0.5, alternative='two-sided')`

Perform a test that the probability of success is  $p$ .

This is an exact, two-sided test of the null hypothesis that the probability of success in a Bernoulli experiment is  $p$ .

**Parameters**

- x** : integer or array\_like  
the number of successes, or if x has length 2, it is the number of successes and the number of failures.
- n** : integer  
the number of trials. This is ignored if x gives both the number of successes and failures
- p** : float, optional  
The hypothesized probability of success.  $0 \leq p \leq 1$ . The default value is  $p = 0.5$
- alternative** : {'two-sided', 'greater', 'less'}, optional  
Indicates the alternative hypothesis. The default value is 'two-sided'.

**Returns**

- p-value** : float  
The p-value of the hypothesis test

### References

[R614]

`scipy.stats.fligner(*args, **kws)`

Perform Fligner-Killeen test for equality of variance.

Fligner's test tests the null hypothesis that all input samples are from populations with equal variances. Fligner-Killeen's test is distribution free when populations are identical [R638].

**Parameters**

- sample1, sample2, ...** : array\_like  
Arrays of sample data. Need not be the same length.
- center** : {'mean', 'median', 'trimmed'}, optional  
Keyword argument controlling which function of the data is used in computing the test statistic. The default is 'median'.

**Returns**

- proportiontocut** : float, optional  
When *center* is ‘trimmed’, this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`.) Default is 0.05.
- statistic** : float  
The test statistic.
- pvalue** : float  
The p-value for the hypothesis test.

**See also:**

**bartlett** A parametric test for equality of k variances in normal samples  
**levene** A robust parametric test for equality of k variances

**Notes**

As with Levene’s test there are three variants of Fligner’s test that differ by the measure of central tendency used in the test. See *levene* for more information.

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [R639].

**References**

[R637], [R638], [R639], [R640]

`scipy.stats.median_test` (\*args, \*\*kws)  
 Mood’s median test.

Test that two or more samples come from populations with the same median.

Let  $n = \text{len}(\text{args})$  be the number of samples. The “grand median” of all the data is computed, and a contingency table is formed by classifying the values in each sample as being above or below the grand median. The contingency table, along with *correction* and *lambda\_*, are passed to `scipy.stats.chi2_contingency` to compute the test statistic and p-value.

**Parameters**

- sample1, sample2, ...** : array\_like  
The set of samples. There must be at least two samples. Each sample must be a one-dimensional sequence containing at least one value. The samples are not required to have the same length.
- ties** : str, optional  
Determines how values equal to the grand median are classified in the contingency table. The string must be one of:

```

"below":
    Values equal to the grand median are counted as
    ↳"below".
"above":
    Values equal to the grand median are counted as
    ↳"above".
"ignore":
    Values equal to the grand median are not counted.
```

The default is “below”.

- correction** : bool, optional  
If True, *and* there are just two samples, apply Yates’ correction for continuity when computing the test statistic associated with the contingency table. Default is True.
- lambda\_** : float or str, optional.

By default, the statistic computed in this test is Pearson’s chi-squared statistic. *lambda\_* allows a statistic from the Cressie-Read power divergence family to be used instead. See *power\_divergence* for details. Default is 1 (Pearson’s chi-squared statistic).

	<b>nan_policy</b> :	{‘propagate’, ‘raise’, ‘omit’}, optional	Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.
<b>Returns</b>	<b>stat</b> :	float	The test statistic. The statistic that is returned is determined by <i>lambda_</i> . The default is Pearson’s chi-squared statistic.
	<b>p</b> :	float	The p-value of the test.
	<b>m</b> :	float	The grand median.
	<b>table</b> :	ndarray	The contingency table. The shape of the table is (2, n), where n is the number of samples. The first row holds the counts of the values above the grand median, and the second row holds the counts of the values below the grand median. The table allows further analysis with, for example, <i>scipy.stats.chi2_contingency</i> , or with <i>scipy.stats.fisher_exact</i> if there are two samples, without having to recompute the table. If <i>nan_policy</i> is “propagate” and there are nans in the input, the return value for <i>table</i> is None.

#### Examples

A biologist runs an experiment in which there are three groups of plants. Group 1 has 16 plants, group 2 has 15 plants, and group 3 has 17 plants. Each plant produces a number of seeds. The seed counts for each group are:

```
Group 1: 10 14 14 18 20 22 24 25 31 31 32 39 43 43 48 49
Group 2: 28 30 31 33 34 35 36 40 44 55 57 61 91 92 99
Group 3:  0  3  9 22 23 25 25 33 34 34 40 45 46 48 62 67 84
```

The following code applies Mood’s median test to these samples.

```
>>> g1 = [10, 14, 14, 18, 20, 22, 24, 25, 31, 31, 32, 39, 43, 43, 48, 49]
>>> g2 = [28, 30, 31, 33, 34, 35, 36, 40, 44, 55, 57, 61, 91, 92, 99]
>>> g3 = [0, 3, 9, 22, 23, 25, 25, 33, 34, 34, 40, 45, 46, 48, 62, 67, 84]
>>> from scipy.stats import median_test
>>> stat, p, med, tbl = median_test(g1, g2, g3)
```

The median is

```
>>> med
34.0
```

and the contingency table is

```
>>> tbl
array([[ 5, 10,  7],
       [11,  5, 10]])
```

$p$  is too large to conclude that the medians are not the same:

```
>>> p
0.12609082774093244
```

The “G-test” can be performed by passing `lambda_="log-likelihood"` to `median_test`.

```
>>> g, p, med, tbl = median_test(g1, g2, g3, lambda_="log-likelihood")
>>> p
0.12224779737117837
```

The median occurs several times in the data, so we’ll get a different result if, for example, `ties="above"` is used:

```
>>> stat, p, med, tbl = median_test(g1, g2, g3, ties="above")
>>> p
0.063873276069553273
```

```
>>> tbl
array([[ 5, 11,  9],
       [11,  4,  8]])
```

This example demonstrates that if the data set is not large and there are values equal to the median, the  $p$ -value can be sensitive to the choice of *ties*.

`scipy.stats.mood(x, y, axis=0)`

Perform Mood’s test for equal scale parameters.

Mood’s two-sample test for scale parameters is a non-parametric test for the null hypothesis that two samples are drawn from the same distribution with the same scale parameter.

**Parameters** `x, y` : array\_like  
 Arrays of sample data.

`axis` : int, optional  
 The axis along which the samples are tested.  $x$  and  $y$  can be of different length along *axis*. If *axis* is None,  $x$  and  $y$  are flattened and the test is done on all values in the flattened arrays.

**Returns** `z` : scalar or ndarray  
 The z-score for the hypothesis test. For 1-D inputs a scalar is returned.

**p-value** : scalar ndarray  
 The p-value for the hypothesis test.

See also:

**fligner** A non-parametric test for the equality of  $k$  variances  
**ansari** A non-parametric test for the equality of 2 variances  
**bartlett** A parametric test for equality of  $k$  variances in normal samples  
**levene** A parametric test for equality of  $k$  variances

**Notes**

The data are assumed to be drawn from probability distributions  $f(x)$  and  $f(x/s) / s$  respectively, for some probability density function  $f$ . The null hypothesis is that  $s == 1$ .

For multi-dimensional arrays, if the inputs are of shapes  $(n_0, n_1, n_2, n_3)$  and  $(n_0, m_1, n_2, n_3)$ , then if `axis=1`, the resulting `z` and `p` values will have shape  $(n_0, n_2, n_3)$ . Note that `n1` and `m1` don't have to be equal, but the other dimensions do.

**Examples**

```
>>> from scipy import stats
>>> np.random.seed(1234)
>>> x2 = np.random.randn(2, 45, 6, 7)
>>> x1 = np.random.randn(2, 30, 6, 7)
>>> z, p = stats.mood(x1, x2, axis=1)
>>> p.shape
(2, 6, 7)
```

Find the number of points where the difference in scale is not significant:

```
>>> (p > 0.1).sum()
74
```

Perform the test with different scales:

```
>>> x1 = np.random.randn(2, 30)
>>> x2 = np.random.randn(2, 35) * 10.0
>>> stats.mood(x1, x2, axis=1)
(array([-5.7178125 , -5.25342163]), array([ 1.07904114e-08,  1.49299218e-07]))
```

<code>boxcox(x[, lmbda, alpha])</code>	Return a positive dataset transformed by a Box-Cox power transformation.
<code>boxcox_normmax(x[, brack, method])</code>	Compute optimal Box-Cox transform parameter for input data.
<code>boxcox_llf(lmb, data)</code>	The boxcox log-likelihood function.
<code>entropy(pk[, qk, base])</code>	Calculate the entropy of a distribution for given probability values.

`scipy.stats.boxcox(x, lmbda=None, alpha=None)`

Return a positive dataset transformed by a Box-Cox power transformation.

**Parameters** `x` : ndarray

Input array. Should be 1-dimensional.

**lmbda** : {None, scalar}, optional

If `lmbda` is not None, do the transformation for that value.

If `lmbda` is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument.

**alpha** : {None, float}, optional

If `alpha` is not None, return the  $100 * (1-\alpha)\%$  confidence interval for `lmbda` as the third output argument. Must be between 0.0 and 1.0.

**Returns**

**boxcox** : ndarray

Box-Cox power transformed array.

**maxlog** : float, optional

If the `lmbda` parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.

**(min\_ci, max\_ci)** : tuple of float, optional

If *lambda* parameter is None and *alpha* is not None, this returned tuple of floats represents the minimum and maximum confidence limits given *alpha*.

**See also:**

*probplot*, *boxcox\_normplot*, *boxcox\_normmax*, *boxcox\_llf*

**Notes**

The Box-Cox transform is given by:

```
y = (x**lambda - 1) / lambda,   for lambda > 0
    log(x),                    for lambda = 0
```

*boxcox* requires the input data to be positive. Sometimes a Box-Cox transformation provides a shift parameter to achieve this; *boxcox* does not. Such a shift parameter is equivalent to adding a positive constant to *x* before calling *boxcox*.

The confidence limits returned when *alpha* is provided give the interval where:

$$llf(\hat{\lambda}) - llf(\lambda) < \frac{1}{2}\chi^2(1 - \alpha, 1),$$

with *llf* the log-likelihood function and  $\chi^2$  the chi-squared function.

**References**

G.E.P. Box and D.R. Cox, “An Analysis of Transformations”, Journal of the Royal Statistical Society B, 26, 211-252 (1964).

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

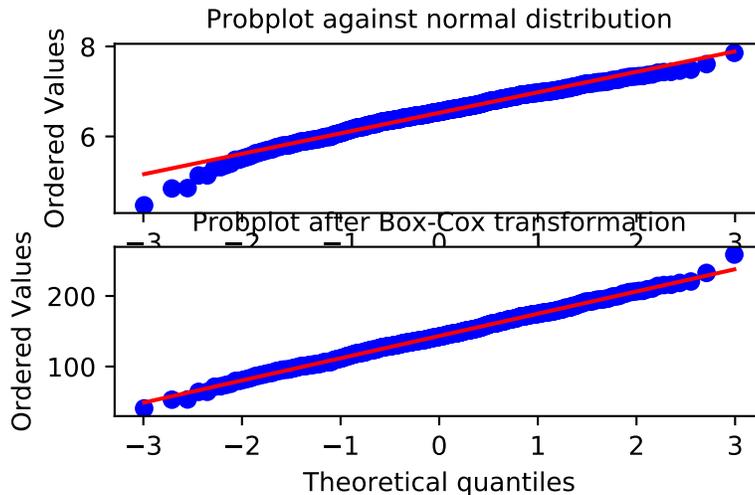

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use *boxcox* to transform the data so it’s closest to normal:

```
>>> ax2 = fig.add_subplot(212)
>>> xt, _ = stats.boxcox(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Box-Cox transformation')
```

```
>>> plt.show()
```

```
scipy.stats.boxcox_normmax(x, brack=(-2.0, 2.0), method='pearsonr')
```

Compute optimal Box-Cox transform parameter for input data.

**Parameters** `x` : array\_like

Input array.

**brack** : 2-tuple, optional

The starting interval for a downhill bracket search with *optimize.brent*. Note that this is in most cases not critical; the final result is allowed to be outside this bracket.

**method** : str, optional

The method to determine the optimal transform parameter (*boxcox* lambda parameter). Options are:

**'pearsonr'** (default)

Maximizes the Pearson correlation coefficient between  $y = \text{boxcox}(x)$  and the expected values for  $y$  if  $x$  would be normally-distributed.

**'mle'**

Minimizes the log-likelihood *boxcox\_llf*. This is the method used in *boxcox*.

**'all'**

Use all optimization methods available, and return all results. Useful to compare different methods.

**Returns** `maxlog` : float or ndarray

The optimal transform parameter found. An array instead of a scalar for `method='all'`.

**See also:**

*boxcox*, *boxcox\_llf*, *boxcox\_normplot*

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234) # make this example reproducible
```

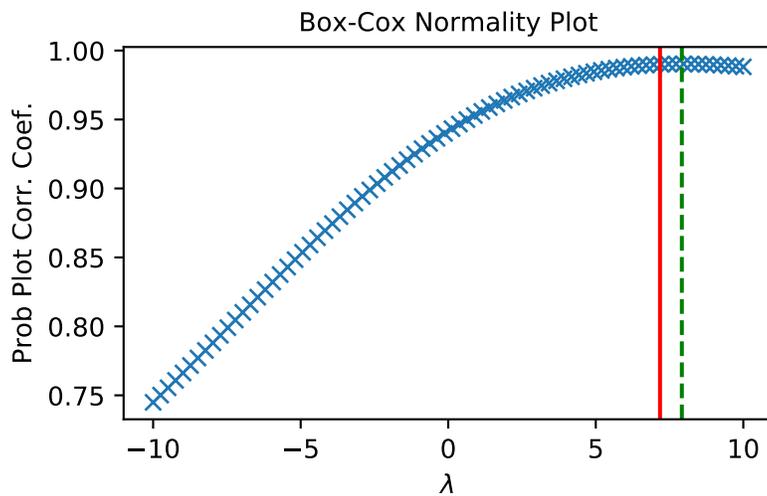

Generate some data and determine optimal lambda in various ways:

```
>>> x = stats.loggamma.rvs(5, size=30) + 5
>>> y, lmax_mle = stats.boxcox(x)
>>> lmax_pearsonr = stats.boxcox_normmax(x)
```

```
>>> lmax_mle
7.177...
>>> lmax_pearsonr
7.916...
>>> stats.boxcox_normmax(x, method='all')
array([ 7.91667384,  7.17718692])
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax_mle, color='r')
>>> ax.axvline(lmax_pearsonr, color='g', ls='--')
```

```
>>> plt.show()
```

`scipy.stats.boxcox_llf(lmb, data)`

The boxcox log-likelihood function.

**Parameters** **lmb** : scalar

Parameter for Box-Cox transformation. See `boxcox` for details.

**data** : array\_like

Data to calculate Box-Cox log-likelihood for. If `data` is multi-dimensional, the log-likelihood is calculated along the first axis.

**Returns** **llf** : float or ndarray

Box-Cox log-likelihood of `data` given `lmb`. A float for 1-D `data`, an array otherwise.

**See also:**

`boxcox`, `probplot`, `boxcox_normplot`, `boxcox_normmax`

**Notes**

The Box-Cox log-likelihood function is defined here as

$$llf = (\lambda - 1) \sum_i (\log(x_i)) - N/2 \log(\sum_i (y_i - \bar{y})^2 / N),$$

where `y` is the Box-Cox transformed input data `x`.

### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
>>> np.random.seed(1245)
```

Generate some random variates and calculate Box-Cox log-likelihood values for them for a range of lambda values:

```
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lambda in enumerate(lmbdas):
...     llf[ii] = stats.boxcox_llf(lambda, x)
```

Also find the optimal lambda value with `boxcox`:

```
>>> x_most_normal, lambda_optimal = stats.boxcox(x)
```

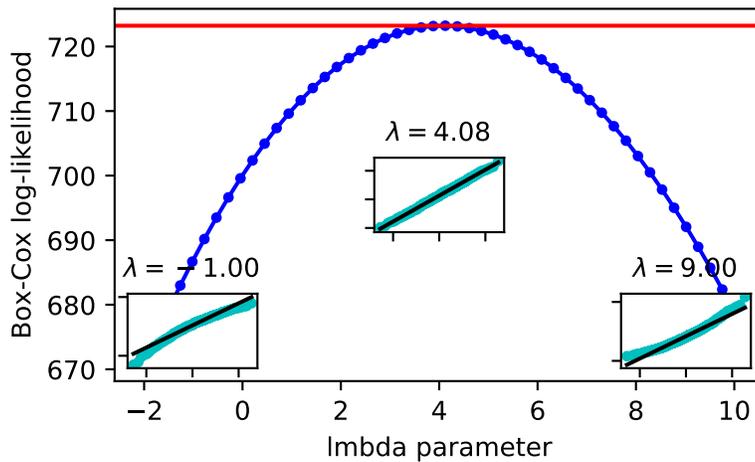

Plot the log-likelihood as function of lambda. Add the optimal lambda as a horizontal line to check that that's really the optimum:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.boxcox_llf(lambda_optimal, x), color='r')
>>> ax.set_xlabel('lambda parameter')
>>> ax.set_ylabel('Box-Cox log-likelihood')
```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with `boxcox` looks closest to normal:

```
>>> locs = [3, 10, 4] # 'lower left', 'center', 'lower right'
>>> for lambda, loc in zip([-1, lambda_optimal, 9], locs):
...     xt = stats.boxcox(x, lambda=lambda)
...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20%", height="20%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title('$\lambda=%1.2f$' % lambda)
```

```
>>> plt.show()
```

`scipy.stats.entropy(pk, qk=None, base=None)`

Calculate the entropy of a distribution for given probability values.

If only probabilities  $pk$  are given, the entropy is calculated as  $S = -\sum(pk * \log(pk), axis=0)$ .

If  $qk$  is not None, then compute the Kullback-Leibler divergence  $S = \sum(pk * \log(pk / qk), axis=0)$ .

This routine will normalize  $pk$  and  $qk$  if they don't sum to 1.

**Parameters**

- pk** : sequence  
Defines the (discrete) distribution.  $pk[i]$  is the (possibly unnormalized) probability of event  $i$ .
- qk** : sequence, optional  
Sequence against which the relative entropy is computed. Should be in the same format as  $pk$ .
- base** : float, optional  
The logarithmic base to use, defaults to  $e$  (natural logarithm).

**Returns**

- S** : float  
The calculated entropy.

---

`wasserstein_distance(u_values, v_values[, ...])`      Compute the first Wasserstein distance between two 1D distributions.

---

`energy_distance(u_values, v_values[, ...])`      Compute the energy distance between two 1D distributions.

---

`scipy.stats.wasserstein_distance(u_values, v_values, u_weights=None, v_weights=None)`

Compute the first Wasserstein distance between two 1D distributions.

This distance is also known as the earth mover's distance, since it can be seen as the minimum amount of "work" required to transform  $u$  into  $v$ , where "work" is measured as the amount of distribution weight that must be moved, multiplied by the distance it has to be moved.

New in version 1.0.0.

**Parameters**

- u\_values, v\_values** : array\_like  
Values observed in the (empirical) distribution.
- u\_weights, v\_weights** : array\_like, optional  
Weight for each value. If unspecified, each value is assigned the same weight.  $u\_weights$  (resp.  $v\_weights$ ) must have the same length as  $u\_values$

**Returns** **distance** : float (resp. *v\_values*). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.  
The computed distance between the distributions.

**Notes**

The first Wasserstein distance between the distributions  $u$  and  $v$  is:

$$l_1(u, v) = \inf_{\pi \in \Gamma(u, v)} \int_{\mathbb{R} \times \mathbb{R}} |x - y| d\pi(x, y)$$

where  $\Gamma(u, v)$  is the set of (probability) distributions on  $\mathbb{R} \times \mathbb{R}$  whose marginals are  $u$  and  $v$  on the first and second factors respectively.

If  $U$  and  $V$  are the respective CDFs of  $u$  and  $v$ , this distance also equals to:

$$l_1(u, v) = \int_{-\infty}^{+\infty} |U - V|$$

See [R711] for a proof of the equivalence of both definitions.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

**References**

[R710], [R711]

**Examples**

```
>>> from scipy.stats import wasserstein_distance
>>> wasserstein_distance([0, 1, 3], [5, 6, 8])
5.0
>>> wasserstein_distance([0, 1], [0, 1], [3, 1], [2, 2])
0.25
>>> wasserstein_distance([3.4, 3.9, 7.5, 7.8], [4.5, 1.4],
...                       [1.4, 0.9, 3.1, 7.2], [3.2, 3.5])
4.0781331438047861
```

`scipy.stats.energy_distance` (*u\_values*, *v\_values*, *u\_weights=None*, *v\_weights=None*)

Compute the energy distance between two 1D distributions.

New in version 1.0.0.

**Parameters** **u\_values, v\_values** : array\_like  
Values observed in the (empirical) distribution.  
**u\_weights, v\_weights** : array\_like, optional  
Weight for each value. If unspecified, each value is assigned the same weight. *u\_weights* (resp. *v\_weights*) must have the same length as *u\_values* (resp. *v\_values*). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

**Returns** **distance** : float  
The computed distance between the distributions.

**Notes**

The energy distance between two distributions  $u$  and  $v$ , whose respective CDFs are  $U$  and  $V$ , equals to:

$$D(u, v) = (2\mathbb{E}|X - Y| - \mathbb{E}|X - X'| - \mathbb{E}|Y - Y'|)^{1/2}$$

where  $X$  and  $X'$  (resp.  $Y$  and  $Y'$ ) are independent random variables whose probability distribution is  $u$  (resp.  $v$ ).

As shown in [R630], for one-dimensional real-valued variables, the energy distance is linked to the non-distribution-free version of the Cramer-von Mises distance:

$$D(u, v) = \sqrt{2}l_2(u, v) = \left( 2 \int_{-\infty}^{+\infty} (U - V)^2 \right)^{1/2}$$

Note that the common Cramer-von Mises criterion uses the distribution-free version of the distance. See [R630] (section 2), for more details about both versions of the distance.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

>>> energy_distance([0, 8], [0, 8], [3, 1], [2, 2])
1.0000000000000002
>>> energy_distance([0.7, 7.4, 2.4, 6.8], [1.4, 8. ],
...                 [2.1, 4.2, 7.4, 8. ], [7.6, 8.8])
0.88003340976158217
```

### 5.27.5 Circular statistical functions

<code>circmean(samples[, high, low, axis])</code>	Compute the circular mean for samples in a range.
<code>circvar(samples[, high, low, axis])</code>	Compute the circular variance for samples assumed to be in a range
<code>circstd(samples[, high, low, axis])</code>	Compute the circular standard deviation for samples assumed to be in the range [low to high].

`scipy.stats.circmean` (*samples, high=6.283185307179586, low=0, axis=None*)

Compute the circular mean for samples in a range.

**Parameters**

- samples** : array\_like  
Input array.
- high** : float or int, optional  
High boundary for circular mean range. Default is  $2 * \pi$ .
- low** : float or int, optional  
Low boundary for circular mean range. Default is 0.
- axis** : int, optional  
Axis along which means are computed. The default is to compute the mean of the flattened array.

**Returns**

- circmean** : float  
Circular mean.

**Examples**

```
>>> from scipy.stats import circmean
>>> circmean([0.1, 2*np.pi+0.2, 6*np.pi+0.3])
0.2
```

```
>>> from scipy.stats import circmean
>>> circmean([0.2, 1.4, 2.6], high = 1, low = 0)
0.4
```

`scipy.stats.circvar` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None)

Compute the circular variance for samples assumed to be in a range

**Parameters**

- samples** : array\_like  
Input array.
- low** : float or int, optional  
Low boundary for circular variance range. Default is 0.
- high** : float or int, optional  
High boundary for circular variance range. Default is  $2\pi$ .
- axis** : int, optional  
Axis along which variances are computed. The default is to compute the variance of the flattened array.

**Returns**

- circvar** : float  
Circular variance.

**Notes**

This uses a definition of circular variance that in the limit of small angles returns a number close to the ‘linear’ variance.

**Examples**

```
>>> from scipy.stats import circvar
>>> circvar([0, 2*np.pi/3, 5*np.pi/3])
2.19722457734
```

`scipy.stats.circstd` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None)

Compute the circular standard deviation for samples assumed to be in the range [low to high].

**Parameters**

- samples** : array\_like  
Input array.
- low** : float or int, optional  
Low boundary for circular standard deviation range. Default is 0.
- high** : float or int, optional  
High boundary for circular standard deviation range. Default is  $2\pi$ .
- axis** : int, optional  
Axis along which standard deviations are computed. The default is to compute the standard deviation of the flattened array.

**Returns**

- circstd** : float  
Circular standard deviation.

**Notes**

This uses a definition of circular standard deviation that in the limit of small angles returns a number close to the ‘linear’ standard deviation.

*Examples*

```
>>> from scipy.stats import circstd
>>> circstd([0, 0.1*np.pi/2, 0.001*np.pi, 0.03*np.pi/2])
0.063564063306
```

### 5.27.6 Contingency table functions

<code>chi2_contingency(observed[, correction, lambda_])</code>	Chi-square test of independence of variables in a contingency table.
<code>contingency.expected_freq(observed)</code>	Compute the expected frequencies from a contingency table.
<code>contingency.margins(a)</code>	Return a list of the marginal sums of the array <i>a</i> .
<code>fisher_exact(table[, alternative])</code>	Performs a Fisher exact test on a 2x2 contingency table.

`scipy.stats.chi2_contingency` (*observed*, *correction=True*, *lambda\_=None*)

Chi-square test of independence of variables in a contingency table.

This function computes the chi-square statistic and p-value for the hypothesis test of independence of the observed frequencies in the contingency table [R618] *observed*. The expected frequencies are computed based on the marginal sums under the assumption of independence; see `scipy.stats.contingency.expected_freq`. The number of degrees of freedom is (expressed using numpy functions and attributes):

```
dof = observed.size - sum(observed.shape) + observed.ndim - 1
```

**Parameters** **observed** : array\_like

The contingency table. The table contains the observed frequencies (i.e. number of occurrences) in each category. In the two-dimensional case, the table is often described as an “R x C table”.

**correction** : bool, optional

If True, *and* the degrees of freedom is 1, apply Yates’ correction for continuity. The effect of the correction is to adjust each observed value by 0.5 towards the corresponding expected value.

**lambda\_** : float or str, optional.

By default, the statistic computed in this test is Pearson’s chi-squared statistic [R619]. *lambda\_* allows a statistic from the Cressie-Read power divergence family [R620] to be used instead. See `power_divergence` for details.

**Returns** **chi2** : float

The test statistic.

**p** : float

The p-value of the test

**dof** : int

Degrees of freedom

**expected** : ndarray, same shape as *observed*

The expected frequencies, based on the marginal sums of the table.

**See also:**

`contingency.expected_freq`, `fisher_exact`, `chisquare`, `power_divergence`

### Notes

An often quoted guideline for the validity of this calculation is that the test should be used only if the observed and expected frequency in each cell is at least 5.

This is a test for the independence of different categories of a population. The test is only meaningful when the dimension of *observed* is two or more. Applying the test to a one-dimensional table will always result in *expected* equal to *observed* and a chi-square statistic equal to 0.

This function does not handle masked arrays, because the calculation does not make sense with missing values.

Like `stats.chisquare`, this function computes a chi-square statistic; the convenience this function provides is to figure out the expected frequencies and degrees of freedom from the given contingency table. If these were already known, and if the Yates' correction was not required, one could use `stats.chisquare`. That is, if one calls:

```
chi2, p, dof, ex = chi2_contingency(obs, correction=False)
```

then the following is true:

```
(chi2, p) == stats.chisquare(obs.ravel(), f_exp=ex.ravel(),
                             ddof=obs.size - 1 - dof)
```

The `lambda_` argument was added in version 0.13.0 of `scipy`.

### References

[R618], [R619], [R620]

### Examples

A two-way example (2 x 3):

```
>>> from scipy.stats import chi2_contingency
>>> obs = np.array([[10, 10, 20], [20, 20, 20]])
>>> chi2_contingency(obs)
(2.7777777777777777,
 0.24935220877729619,
 2,
 array([[ 12.,  12.,  16.],
        [ 18.,  18.,  24.]])
```

Perform the test using the log-likelihood ratio (i.e. the “G-test”) instead of Pearson’s chi-squared statistic.

```
>>> g, p, dof, expctd = chi2_contingency(obs, lambda_="log-likelihood")
>>> g, p
(2.7688587616781319, 0.25046668010954165)
```

A four-way example (2 x 2 x 2 x 2):

```
>>> obs = np.array(
...     [[[[12, 17],
...         [11, 16]],
...        [[11, 12],
...         [15, 16]]],
...     [[[[23, 15],
...         [30, 22]],
...        [[14, 17],
...         [15, 16]]]])
>>> chi2_contingency(obs)
(8.7584514426741897,
```

```

0.64417725029295503,
11,
array([[[[ 14.15462386,  14.15462386],
          [ 16.49423111,  16.49423111]],
        [[ 11.2461395 ,  11.2461395 ],
          [ 13.10500554,  13.10500554]]],
       [[ 19.5591166 ,  19.5591166 ],
          [ 22.79202844,  22.79202844]],
       [[ 15.54012004,  15.54012004],
          [ 18.10873492,  18.10873492]]]])
    
```

`scipy.stats.contingency.expected_freq(observed)`

Compute the expected frequencies from a contingency table.

Given an  $n$ -dimensional contingency table of observed frequencies, compute the expected frequencies for the table based on the marginal sums under the assumption that the groups associated with each dimension are independent.

**Parameters**    **observed** : array\_like

The table of observed frequencies. (While this function can handle a 1-D array, that case is trivial. Generally *observed* is at least 2-D.)

**Returns**        **expected** : ndarray of float64

The expected frequencies, based on the marginal sums of the table. Same shape as *observed*.

### Examples

```

>>> observed = np.array([[10, 10, 20],[20, 20, 20]])
>>> from scipy.stats import expected_freq
>>> expected_freq(observed)
array([[ 12.,  12.,  16.],
       [ 18.,  18.,  24.]])
    
```

`scipy.stats.contingency.margins(a)`

Return a list of the marginal sums of the array *a*.

**Parameters**    **a** : ndarray

The array for which to compute the marginal sums.

**Returns**        **margsums** : list of ndarrays

A list of length *a.ndim*. *margsums[k]* is the result of summing *a* over all axes except *k*; it has the same number of dimensions as *a*, but the length of each axis except axis *k* will be 1.

### Examples

```

>>> a = np.arange(12).reshape(2, 6)
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11]])
>>> m0, m1 = margins(a)
>>> m0
array([[15],
       [51]])
>>> m1
array([[ 6,  8, 10, 12, 14, 16]])
    
```

```

>>> b = np.arange(24).reshape(2, 3, 4)
>>> m0, m1, m2 = margins(b)
    
```

```

>>> m0
array([[ 66]],
      [[210]])
>>> m1
array([[ 60],
      [ 92],
      [124]])
>>> m2
array([[60, 66, 72, 78]])

```

`scipy.stats.fisher_exact` (*table*, *alternative='two-sided'*)

Performs a Fisher exact test on a 2x2 contingency table.

**Parameters**

- table** : array\_like of ints  
A 2x2 contingency table. Elements should be non-negative integers.
- alternative** : {'two-sided', 'less', 'greater'}, optional  
Which alternative hypothesis to the null hypothesis the test uses. Default is 'two-sided'.

**Returns**

- oddsratio** : float  
This is prior odds ratio and not a posterior estimate.
- p\_value** : float  
P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

**See also:**

**chi2\_contingency**

Chi-square test of independence of variables in a contingency table.

**Notes**

The calculated odds ratio is different from the one R uses. This scipy implementation returns the (more common) “unconditional Maximum Likelihood Estimate”, while R uses the “conditional Maximum Likelihood Estimate”.

For tables with large numbers, the (inexact) chi-square test implemented in the function `chi2_contingency` can also be used.

**Examples**

Say we spend a few days counting whales and sharks in the Atlantic and Indian oceans. In the Atlantic ocean we find 8 whales and 1 shark, in the Indian ocean 2 whales and 5 sharks. Then our contingency table is:

	Atlantic	Indian
whales	8	2
sharks	1	5

We use this table to find the p-value:

```

>>> import scipy.stats as stats
>>> oddsratio, pvalue = stats.fisher_exact([[8, 2], [1, 5]])
>>> pvalue
0.0349...

```

The probability that we would observe this or an even more imbalanced ratio by chance is about 3.5%. A commonly used significance level is 5%—if we adopt that, we can therefore conclude that our observed imbalance is statistically significant; whales prefer the Atlantic while sharks prefer the Indian ocean.

## 5.27.7 Plot-tests

<code>ppcc_max(x[, brack, dist])</code>	Calculate the shape parameter that maximizes the PPCC
<code>ppcc_plot(x, a, b[, dist, plot, N])</code>	Calculate and optionally plot probability plot correlation coefficient.
<code>probplot(x[, sparams, dist, fit, plot, rvalue])</code>	Calculate quantiles for a probability plot, and optionally show the plot.
<code>boxcox_normplot(x, la, lb[, plot, N])</code>	Compute parameters for a Box-Cox normality plot, optionally show it.

`scipy.stats.ppcc_max(x, brack=(0.0, 1.0), dist='tukeylambda')`

Calculate the shape parameter that maximizes the PPCC

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. `ppcc_max` returns the shape parameter that would maximize the probability plot correlation coefficient for the given data to a one-parameter family of distributions.

**Parameters** `x` : array\_like

Input array.

**brack** : tuple, optional

Triple (a,b,c) where (a<b<c). If bracket consists of two numbers (a, c) then they are assumed to be a starting interval for a downhill bracket search (see `scipy.optimize.brent`).

**dist** : str or stats.distributions instance, optional

Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted. The default is 'tukeylambda'.

**Returns**

**shape\_value** : float

The shape parameter at which the probability plot correlation coefficient reaches its max value.

**See also:**

`ppcc_plot`, `probplot`, `boxcox`

**Notes**

The `brack` keyword serves as a starting point which is useful in corner cases. One can use a plot to obtain a rough visual estimate of the location for the maximum to start the search near it.

**References**

[R687], [R688]

**Examples**

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```
>>> from scipy import stats
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000,
...                          random_state=1234567) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

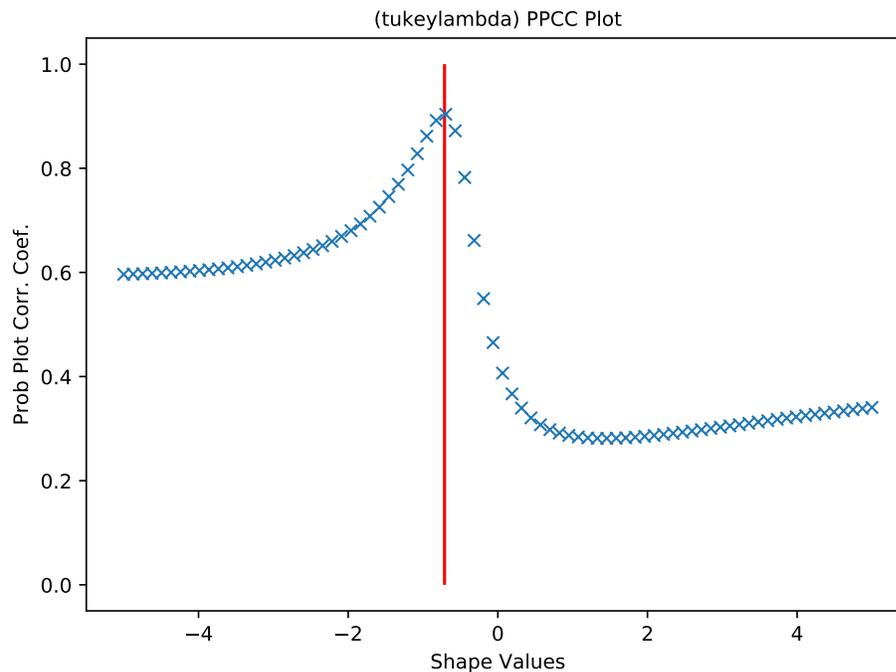

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure(figsize=(8, 6))
```

```
>>> ax = fig.add_subplot(111)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax)
```

We calculate the value where the shape should reach its maximum and a red line is drawn there. The line should coincide with the highest point in the ppcc\_plot.

```
>>> max = stats.ppcc_max(x)
>>> ax.vlines(max, 0, 1, colors='r', label='Expected shape value')
```

```
>>> plt.show()
```

`scipy.stats.ppcc_plot(x, a, b, dist='tukeylambda', plot=None, N=80)`

Calculate and optionally plot probability plot correlation coefficient.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. It cannot be used for distributions without shape parameters (like the normal distribution) or with multiple shape parameters.

By default a Tukey-Lambda distribution (`stats.tukeylambda`) is used. A Tukey-Lambda PPCC plot interpolates from long-tailed to short-tailed distributions via an approximately normal one, and is therefore particularly useful in practice.

**Parameters** `x`: array\_like

Input array.

**a, b**: scalar

Lower and upper bounds of the shape parameter to use.

**dist**: str or `stats.distributions` instance, optional

Distribution or distribution function name. Objects that look enough like a `stats.distributions` instance (i.e. they have a `ppf` method) are also accepted. The default is `'tukeylambda'`.

**plot** : object, optional

If given, plots PPCC against the shape parameter. *plot* is an object that has to have methods “plot” and “text”. The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is `None`, which means that no plot is created.

**N** : int, optional

Number of points on the horizontal axis (equally distributed from *a* to *b*).

**Returns**

**svals** : ndarray

The shape values for which *ppcc* was calculated.

**ppcc** : ndarray

The calculated probability plot correlation coefficient values.

**See also:**

`ppcc_max`, `probplot`, `boxcox_normplot`, `tukeylambda`

### References

J.J. Filliben, “The Probability Plot Correlation Coefficient Test for Normality”, *Technometrics*, Vol. 17, pp. 111-117, 1975.

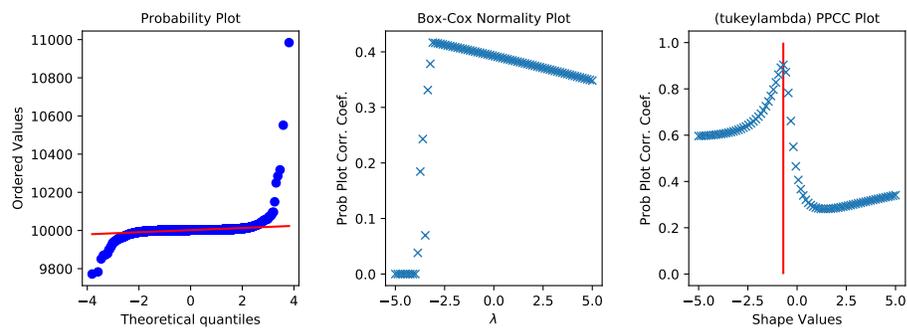

### Examples

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234567)
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```
>>> fig = plt.figure(figsize=(12, 4))
>>> ax1 = fig.add_subplot(131)
>>> ax2 = fig.add_subplot(132)
>>> ax3 = fig.add_subplot(133)
>>> res = stats.probplot(x, plot=ax1)
>>> res = stats.boxcox_normplot(x, -5, 5, plot=ax2)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax3)
>>> ax3.vlines(-0.7, 0, 1, colors='r', label='Expected shape value')
>>> plt.show()
```

`scipy.stats.probplot(x, sparams=(), dist='norm', fit=True, plot=None, rvalue=False)`

Calculate quantiles for a probability plot, and optionally show the plot.

Generates a probability plot of sample data against the quantiles of a specified theoretical distribution (the normal distribution by default). `probplot` optionally calculates a best-fit line for the data and plots the results using Matplotlib or a given plot function.

**Parameters** `x` : array\_like

Sample/response data from which `probplot` creates the plot.

`sparams` : tuple, optional

Distribution-specific shape parameters (shape parameters plus location and scale).

`dist` : str or stats.distributions instance, optional

Distribution or distribution function name. The default is 'norm' for a normal probability plot. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted.

`fit` : bool, optional

Fit a least-squares regression (best-fit) line to the sample data if True (default).

`plot` : object, optional

If given, plots the quantiles and least squares fit. `plot` is an object that has to have methods "plot" and "text". The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

**Returns**

`(osm, osr)` : tuple of ndarrays

Tuple of theoretical quantiles (`osm`, or order statistic medians) and ordered responses (`osr`). `osr` is simply sorted input `x`. For details on how `osm` is calculated see the Notes section.

`(slope, intercept, r)` : tuple of floats, optional

Tuple containing the result of the least-squares fit, if that is performed by `probplot`. `r` is the square root of the coefficient of determination. If `fit=False` and `plot=None`, this tuple is not returned.

### Notes

Even if `plot` is given, the figure is not shown or saved by `probplot`; `plt.show()` or `plt.savefig('figname.png')` should be used after calling `probplot`.

`probplot` generates a probability plot, which should not be confused with a Q-Q or a P-P plot. Statsmodels has more extensive functionality of this type, see `statsmodels.api.ProbPlot`.

The formula used for the theoretical quantiles (horizontal axis of the probability plot) is Filliben's estimate:

```
quantiles = dist.ppf(val), for
    0.5**(1/n), for i = n
    val = (i - 0.3175) / (n + 0.365), for i = 2, ..., n-1
    1 - 0.5**(1/n), for i = 1
```

where `i` indicates the `i`-th ordered value and `n` is the total number of values.

### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> nsample = 100
>>> np.random.seed(7654321)
```

A t distribution with small degrees of freedom:

```
>>> ax1 = plt.subplot(221)
>>> x = stats.t.rvs(3, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A t distribution with larger degrees of freedom:

```
>>> ax2 = plt.subplot(222)
>>> x = stats.t.rvs(25, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A mixture of two normal distributions with broadcasting:

```
>>> ax3 = plt.subplot(223)
>>> x = stats.norm.rvs(loc=[0,5], scale=[1,1.5],
...                   size=(nsample//2,2)).ravel()
>>> res = stats.probplot(x, plot=plt)
```

A standard normal distribution:

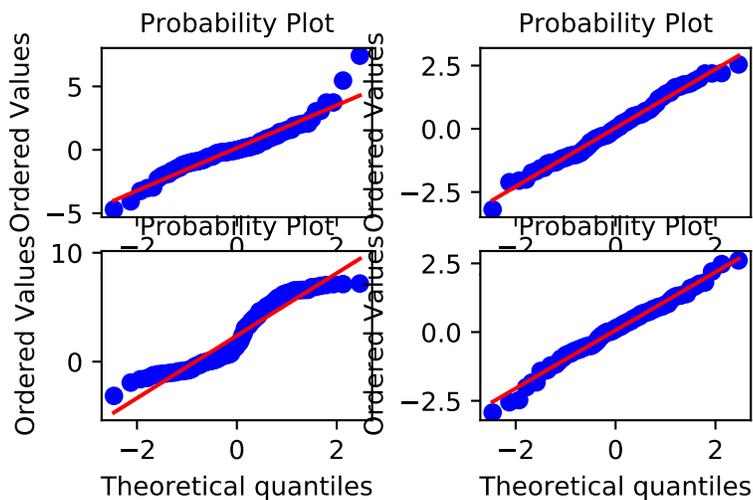

```
>>> ax4 = plt.subplot(224)
>>> x = stats.norm.rvs(loc=0, scale=1, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

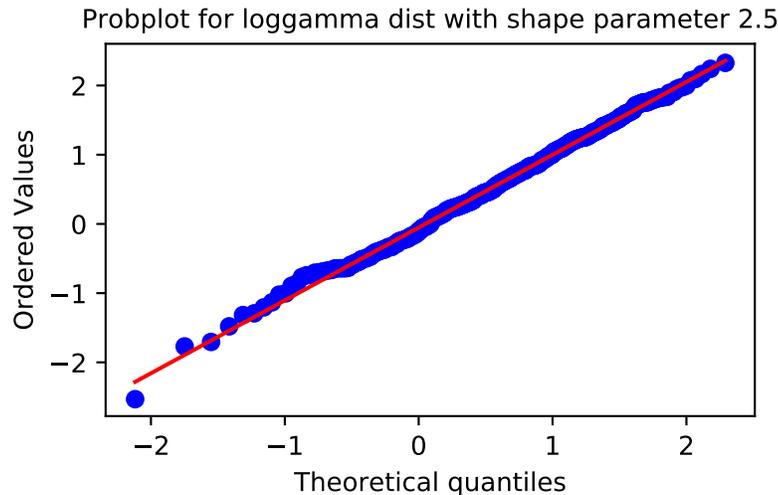

Produce a new figure with a loggamma distribution, using the `dist` and `sparams` keywords:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = stats.loggamma.rvs(c=2.5, size=500)
>>> res = stats.probplot(x, dist=stats.loggamma, sparams=(2.5,), plot=ax)
>>> ax.set_title("Probplot for loggamma dist with shape parameter 2.5")
```

Show the results with Matplotlib:

```
>>> plt.show()
```

`scipy.stats.boxcox_normplot` (*x*, *la*, *lb*, *plot=None*, *N=80*)

Compute parameters for a Box-Cox normality plot, optionally show it.

A Box-Cox normality plot shows graphically what the best transformation parameter is to use in `boxcox` to obtain a distribution that is close to normal.

**Parameters** `x` : array\_like

Input array.

`la`, `lb` : scalar

The lower and upper bounds for the `lambda` values to pass to `boxcox` for Box-Cox transformations. These are also the limits of the horizontal axis of the plot if that is generated.

`plot` : object, optional

If given, plots the quantiles and least squares fit. `plot` is an object that has to have methods “plot” and “text”. The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

`N` : int, optional

Number of points on the horizontal axis (equally distributed from `la` to `lb`).

**Returns** `lmbdas` : ndarray

The `lambda` values for which a Box-Cox transform was done.

`ppcc` : ndarray

Probability Plot Correlation Coefficient, as obtained from `probplot` when fitting the Box-Cox transformed input `x` against a normal distribution.

**See also:**

`probplot`, `boxcox`, `boxcox_normmax`, `boxcox_llf`, `ppcc_max`

**Notes**

Even if `plot` is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.savefig('figname.png')` should be used after calling `probplot`.

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

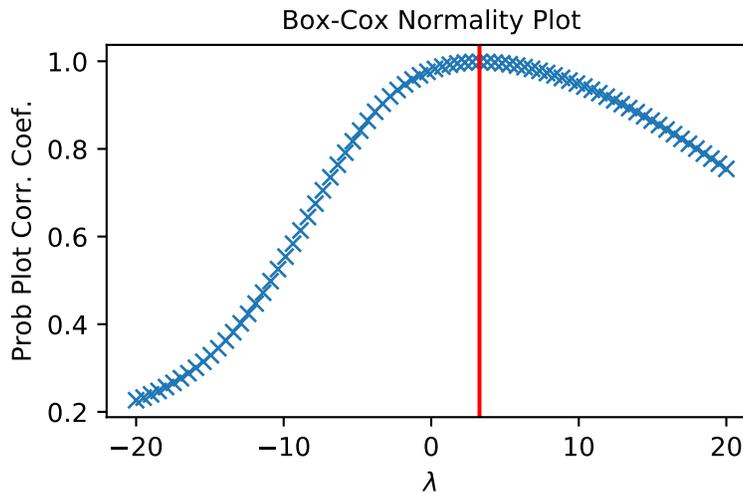

Generate some non-normally distributed data, and create a Box-Cox plot:

```
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal lambda to transform x and plot it in the same plot:

```
>>> _, maxlog = stats.boxcox(x)
>>> ax.axvline(maxlog, color='r')
```

```
>>> plt.show()
```

## 5.27.8 Masked statistics functions

### Statistical functions for masked arrays (`scipy.stats.mstats`)

This module contains a large number of statistical functions that can be used with masked arrays.

Most of these functions are similar to those in `scipy.stats` but might have small differences in the API or in the algorithm used. Since this is a relatively new package, some API changes are still possible.

<code>argstoarray(*args)</code>	Constructs a 2D array from a group of sequences.
<code>chisquare(f_obs[, f_exp, ddof, axis])</code>	Calculate a one-way chi square test.
<code>count_tied_groups(x[, use_missing])</code>	Counts the number of tied values.
<code>describe(a[, axis, ddof, bias])</code>	Computes several descriptive statistics of the passed array.
<code>f_oneway(*args)</code>	Performs a 1-way ANOVA, returning an F-value and probability given any number of groups.
<code>find_repeats(arr)</code>	Find repeats in arr and return a tuple (repeats, repeat_count).
<code>friedmanchisquare(*args)</code>	Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA.

Continued on next page

Table 5.303 – continued from previous page

<code>kendalltau(x, y[, use_ties, use_missing])</code>	Computes Kendall's rank correlation tau on two variables $x$ and $y$ .
<code>kendalltau_seasonal(x)</code>	Computes a multivariate Kendall's rank correlation tau, for seasonal data.
<code>kruskalwallis(*args)</code>	Compute the Kruskal-Wallis H-test for independent samples
<code>ks_twosamp(data1, data2[, alternative])</code>	Computes the Kolmogorov-Smirnov test on two samples.
<code>kurtosis(a[, axis, fisher, bias])</code>	Computes the kurtosis (Fisher or Pearson) of a dataset.
<code>kurtosistest(a[, axis])</code>	Tests whether a dataset has normal kurtosis
<code>linregress(x[, y])</code>	Calculate a linear least-squares regression for two sets of measurements.
<code>mannwhitneyu(x, y[, use_continuity])</code>	Computes the Mann-Whitney statistic
<code>plotting_positions(data[, alpha, beta])</code>	Returns plotting positions (or empirical percentile points) for the data.
<code>mode(a[, axis])</code>	Returns an array of the modal (most common) value in the passed array.
<code>moment(a[, moment, axis])</code>	Calculates the $n$ th moment about the mean for a sample.
<code>mquantiles(a[, prob, alphap, betap, axis, limit])</code>	Computes empirical quantiles for a data array.
<code>msign(x)</code>	Returns the sign of $x$ , or 0 if $x$ is masked.
<code>normaltest(a[, axis])</code>	Tests whether a sample differs from a normal distribution.
<code>obrientransform(*args)</code>	Computes a transform on input data (any number of columns).
<code>pearsonr(x, y)</code>	Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.
<code>plotting_positions(data[, alpha, beta])</code>	Returns plotting positions (or empirical percentile points) for the data.
<code>pointbiserialr(x, y)</code>	Calculates a point biserial correlation coefficient and its p-value.
<code>rankdata(data[, axis, use_missing])</code>	Returns the rank (also known as order statistics) of each data point along the given axis.
<code>scoreatpercentile(data, per[, limit, ...])</code>	Calculate the score at the given 'per' percentile of the sequence $a$ .
<code>sem(a[, axis, ddof])</code>	Calculates the standard error of the mean of the input array.
<code>skew(a[, axis, bias])</code>	Computes the skewness of a data set.
<code>skewtest(a[, axis])</code>	Tests whether the skew is different from the normal distribution.
<code>spearmanr(x, y[, use_ties])</code>	Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.
<code>theilslopes(y[, x, alpha])</code>	Computes the Theil-Sen estimator for a set of points $(x, y)$ .
<code>tmax(a[, upperlimit, axis, inclusive])</code>	Compute the trimmed maximum
<code>tmean(a[, limits, inclusive, axis])</code>	Compute the trimmed mean.
<code>tmin(a[, lowerlimit, axis, inclusive])</code>	Compute the trimmed minimum
<code>trim(a[, limits, inclusive, relative, axis])</code>	Trims an array by masking the data outside some given limits.
<code>trima(a[, limits, inclusive])</code>	Trims an array by masking the data outside some given limits.
<code>trimboth(data[, proportiontocut, inclusive, ...])</code>	Trims the smallest and largest data values.
<code>trimmed_stde(a[, limits, inclusive, axis])</code>	Returns the standard error of the trimmed mean along the given axis.
<code>trimr(a[, limits, inclusive, axis])</code>	Trims an array by masking some proportion of the data on each end.

Continued on next page

Table 5.303 – continued from previous page

<code>trimtail(data[, proportiontocut, tail, ...])</code>	Trims the data by masking values from one tail.
<code>tsem(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed standard error of the mean.
<code>ttest_onesamp(a, popmean[, axis])</code>	Calculates the T-test for the mean of ONE group of scores.
<code>ttest_ind(a, b[, axis, equal_var])</code>	Calculates the T-test for the means of TWO INDEPENDENT samples of scores.
<code>ttest_onesamp(a, popmean[, axis])</code>	Calculates the T-test for the mean of ONE group of scores.
<code>ttest_rel(a, b[, axis])</code>	Calculates the T-test on TWO RELATED samples of scores, a and b.
<code>tvar(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed variance
<code>variation(a[, axis])</code>	Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.
<code>winsorize(a[, limits, inclusive, inplace, axis])</code>	Returns a Winsorized version of the input array.
<code>zmap(scores, compare[, axis, ddof])</code>	Calculate the relative z-scores.
<code>zscore(a[, axis, ddof])</code>	Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.
<code>compare_medians_ms(group_1, group_2[, axis])</code>	Compares the medians from two independent groups along the given axis.
<code>gmean(a[, axis, dtype])</code>	Compute the geometric mean along the specified axis.
<code>hdmedian(data[, axis, var])</code>	Returns the Harrell-Davis estimate of the median along the given axis.
<code>hdquantiles(data[, prob, axis, var])</code>	Computes quantile estimates with the Harrell-Davis method.
<code>hdquantiles_sd(data[, prob, axis])</code>	The standard error of the Harrell-Davis quantile estimates by jackknife.
<code>hmean(a[, axis, dtype])</code>	Calculate the harmonic mean along the specified axis.
<code>idealfourths(data[, axis])</code>	Returns an estimate of the lower and upper quartiles.
<code>kruskal(*args)</code>	Compute the Kruskal-Wallis H-test for independent samples
<code>ks_2samp(data1, data2[, alternative])</code>	Computes the Kolmogorov-Smirnov test on two samples.
<code>median_cihs(data[, alpha, axis])</code>	Computes the alpha-level confidence interval for the median of the data.
<code>meppf(data[, alpha, beta])</code>	Returns plotting positions (or empirical percentile points) for the data.
<code>mjci(data[, prob, axis])</code>	Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.
<code>mquantiles_cimj(data[, prob, alpha, axis])</code>	Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.
<code>rsh(data[, points])</code>	Evaluates Rosenblatt's shifted histogram estimators for each data point.
<code>sen_seasonal_slopes(x)</code>	
<code>trimmed_mean(a[, limits, inclusive, ...])</code>	
<code>trimmed_mean_ci(data[, limits, inclusive, ...])</code>	Selected confidence interval of the trimmed mean along the given axis.
<code>trimmed_std(a[, limits, inclusive, ...])</code>	
<code>trimmed_var(a[, limits, inclusive, ...])</code>	
<code>ttest_1samp(a, popmean[, axis])</code>	Calculates the T-test for the mean of ONE group of scores.

`scipy.stats.mstats.argstoarray(*args)`

Constructs a 2D array from a group of sequences.

Sequences are filled with missing values to match the length of the longest sequence.

**Parameters** `args` : sequences

**Returns** `argstoarray` : `MaskedArray` Group of sequences.

A ( $m \times n$ ) masked array, where  $m$  is the number of arguments and  $n$  the length of the longest argument.

### Notes

`numpy.ma.row_stack` has identical behavior, but is called with a sequence of sequences.

`scipy.stats.mstats.chisquare(f_obs, f_exp=None, ddof=0, axis=0)`

Calculate a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

**Parameters** `f_obs` : array\_like

Observed frequencies in each category.

`f_exp` : array\_like, optional

Expected frequencies in each category. By default the categories are assumed to be equally likely.

`ddof` : int, optional

“Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where  $k$  is the number of observed frequencies. The default value of `ddof` is 0.

`axis` : int or None, optional

The axis of the broadcast result of `f_obs` and `f_exp` along which to apply the test. If `axis` is None, all values in `f_obs` are treated as a single data set.

**Returns** `chisq` : float or ndarray Default is 0.

The chi-squared test statistic. The value is a float if `axis` is None or `f_obs` and `f_exp` are 1-D.

`p` : float or ndarray

The p-value of the test. The value is a float if `ddof` and the return value `chisq` are scalars.

### See also:

`power_divergence`, `mstats.chisquare`

### Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom,  $k-1$ , are for the case when no parameters of the distribution are estimated. If  $p$  parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are  $k-1-p$ . If the parameters are estimated in a different way, then the dof can be between  $k-1-p$  and  $k-1$ . However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

### References

[R671], [R672]

### Examples

When just `f_obs` is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With *f\_exp* the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When *f\_obs* is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2.          ,  6.66666667]), array([ 0.84914504,  0.24663415]))
```

By setting *axis=None*, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

*ddof* is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with *ddof*.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

*f\_obs* and *f\_exp* are also broadcast. In the following, *f\_obs* has shape (6,) and *f\_exp* has shape (2, 6), so the result of broadcasting *f\_obs* and *f\_exp* has shape (2, 6). To compute the desired chi-squared statistics, we use *axis=1*:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
...          f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...          axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

`scipy.stats.mstats.count_tied_groups(x, use_missing=False)`

Counts the number of tied values.

**Parameters**

- x**: sequence
- Sequence of data on which to counts the ties
- use\_missing**: bool, optional
- Whether to consider missing values as tied.

**Returns**

- count\_tied\_groups**: dict
- Returns a dictionary (nb of ties: nb of groups).

*Examples*

```
>>> from scipy.stats import mstats
>>> z = [0, 0, 0, 2, 2, 2, 3, 3, 4, 5, 6]
>>> mstats.count_tied_groups(z)
{2: 1, 3: 2}
```

In the above example, the ties were 0 (3x), 2 (3x) and 3 (2x).

```
>>> z = np.ma.array([0, 0, 1, 2, 2, 2, 3, 3, 4, 5, 6])
>>> mstats.count_tied_groups(z)
{2: 2, 3: 1}
>>> z[[1,-1]] = np.ma.masked
>>> mstats.count_tied_groups(z, use_missing=True)
{2: 2, 3: 1}
```

`scipy.stats.mstats.describe` (*a*, *axis=0*, *ddof=0*, *bias=True*)

Computes several descriptive statistics of the passed array.

<b>Parameters</b>	<b>a</b> : array_like	Data array
	<b>axis</b> : int or None, optional	Axis along which to calculate statistics. Default 0. If None, compute over the whole array <i>a</i> .
	<b>ddof</b> : int, optional	degree of freedom (default 0); note that default ddof is different from the same routine in <code>stats.describe</code>
	<b>bias</b> : bool, optional	If False, then the skewness and kurtosis calculations are corrected for statistical bias.
<b>Returns</b>	<b>nobs</b> : int	(size of the data (discarding missing values))
	<b>minmax</b> : (int, int)	min, max
	<b>mean</b> : float	arithmetic mean
	<b>variance</b> : float	unbiased variance
	<b>skewness</b> : float	biased skewness
	<b>kurtosis</b> : float	biased kurtosis

### Examples

```
>>> from scipy.stats.mstats import describe
>>> ma = np.ma.array(range(6), mask=[0, 0, 0, 1, 1, 1])
>>> describe(ma)
DescribeResult(nobs=3, minmax=(masked_array(data = 0,
      mask = False,
      fill_value = 999999)
, masked_array(data = 2,
      mask = False,
      fill_value = 999999)
), mean=1.0, variance=0.66666666666666663, skewness=masked_array(data = 0.0,
      mask = False,
      fill_value = 1e+20)
, kurtosis=-1.5)
```

`scipy.stats.mstats.f_oneway(*args)`

Performs a 1-way ANOVA, returning an F-value and probability given any number of groups. From Heiman, pp.394-7.

Usage: `f_oneway(*args)`, where `*args` is 2 or more arrays, one per treatment group.

**Returns**

- statistic** : float  
The computed F-value of the test.
- pvalue** : float  
The associated p-value from the F-distribution.

`scipy.stats.mstats.find_repeats(arr)`

Find repeats in `arr` and return a tuple (`repeats`, `repeat_count`).

The input is cast to float64. Masked values are discarded.

**Parameters**

- arr** : sequence  
Input array. The array is flattened if it is not 1D.

**Returns**

- repeats** : ndarray  
Array of repeated values.
- counts** : ndarray  
Array of counts.

`scipy.stats.mstats.friedmanchisquare(*args)`

Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA. This function calculates the Friedman Chi-square test for repeated measures and returns the result, along with the associated probability value.

Each input is considered a given group. Ideally, the number of treatments among each group should be equal. If this is not the case, only the first `n` treatments are taken into account, where `n` is the number of treatments of the smallest group. If a group has some missing values, the corresponding treatments are masked in the other groups. The test statistic is corrected for ties.

Masked values in one group are propagated to the other groups.

**Returns**

- statistic** : float  
the test statistic.
- pvalue** : float  
the associated p-value.

`scipy.stats.mstats.kendalltau(x, y, use_ties=True, use_missing=False)`

Computes Kendall's rank correlation tau on two variables `x` and `y`.

**Parameters**

- x** : sequence  
First data list (for example, time).
- y** : sequence  
Second data list.
- use\_ties** : {True, False}, optional  
Whether ties correction should be performed.
- use\_missing** : {False, True}, optional  
Whether missing data should be allocated a rank of 0 (False) or the average rank (True)

**Returns**

- correlation** : float  
Kendall tau
- pvalue** : float  
Approximate 2-side p-value.

`scipy.stats.mstats.kendalltau_seasonal(x)`

Computes a multivariate Kendall's rank correlation tau, for seasonal data.

**Parameters**

- x** : 2-D ndarray

Array of seasonal data, with seasons in columns.

`scipy.stats.mstats.kruskalwallis(*args)`

Compute the Kruskal-Wallis H-test for independent samples

**Parameters** **sample1, sample2, ...** : array\_like  
Two or more arrays with the sample measurements can be given as arguments.

**Returns** **statistic** : float  
The Kruskal-Wallis H statistic, corrected for ties

**pvalue** : float  
The p-value for the test using the assumption that H has a chi square distribution

#### Notes

For more details on *kruskal*, see *stats.kruskal*.

`scipy.stats.mstats.ks_twosamp(data1, data2, alternative='two-sided')`

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

**Parameters** **data1** : array\_like  
First data set

**data2** : array\_like  
Second data set

**alternative** : {'two-sided', 'less', 'greater'}, optional  
Indicates the alternative hypothesis. Default is 'two-sided'.

**Returns** **d** : float  
Value of the Kolmogorov Smirnov test

**p** : float  
Corresponding p-value.

`scipy.stats.mstats.kurtosis(a, axis=0, fisher=True, bias=True)`

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If bias is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use *kurtosistest* to see if result is close enough to normal.

**Parameters** **a** : array  
data for which the kurtosis is calculated

**axis** : int or None, optional  
Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array *a*.

**fisher** : bool, optional  
If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).

**bias** : bool, optional  
If False, then the calculations are corrected for statistical bias.

**Returns** **kurtosis** : array  
The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.

*Notes*

For more details about *kurtosis*, see *stats.kurtosis*.

`scipy.stats.mstats.kurtosistest` (*a*, *axis=0*)

Tests whether a dataset has normal kurtosis

<b>Parameters</b>	<b>a</b> : array	array of the sample data
	<b>axis</b> : int or None, optional	Axis along which to compute test. Default is 0. If None, compute over the whole array <i>a</i> .
<b>Returns</b>	<b>statistic</b> : float	The computed z-score for this test.
	<b>pvalue</b> : float	The 2-sided p-value for the hypothesis test

*Notes*

For more details about *kurtosistest*, see *stats.kurtosistest*.

`scipy.stats.mstats.linregress` (*x*, *y=None*)

Calculate a linear least-squares regression for two sets of measurements.

<b>Parameters</b>	<b>x, y</b> : array_like	Two sets of measurements. Both arrays should have the same length. If only <i>x</i> is given (and <i>y=None</i> ), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension.
<b>Returns</b>	<b>slope</b> : float	slope of the regression line
	<b>intercept</b> : float	intercept of the regression line
	<b>rvalue</b> : float	correlation coefficient
	<b>pvalue</b> : float	two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero, using Wald Test with t-distribution of the test statistic.
	<b>stderr</b> : float	Standard error of the estimated gradient.

See also:

`scipy.optimize.curve_fit`

Use non-linear least squares to fit a function to data.

`scipy.optimize.leastsq`

Minimize the sum of squares of a set of equations.

*Notes*

Missing values are considered pair-wise: if a value is missing in *x*, the corresponding value in *y* is masked.

*Examples*

```

>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = np.random.random(10)
>>> y = np.random.random(10)
>>> slope, intercept, r_value, p_value, std_err = stats.linregress(x, y)

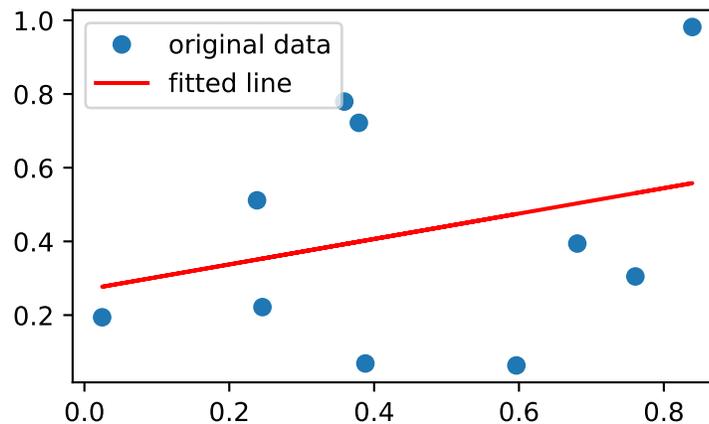

```

To get coefficient of determination (`r_squared`)

```
>>> print("r-squared:", r_value**2)
r-squared: 0.080402268539
```

Plot the data along with the fitted line

```
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, intercept + slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

`scipy.stats.mstats.mannwhitneyu(x, y, use_continuity=True)`

Computes the Mann-Whitney statistic

Missing values in *x* and/or *y* are discarded.

**Parameters**

- x** : sequence  
Input
- y** : sequence  
Input
- use\_continuity** : {True, False}, optional  
Whether a continuity correction (1/2.) should be taken into account.

**Returns**

- statistic** : float  
The Mann-Whitney statistics
- pvalue** : float  
Approximate p-value assuming a normal distribution.

`scipy.stats.mstats.plotting_positions(data, alpha=0.4, beta=0.4)`

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as  $(i-\alpha)/(n+1-\alpha-\beta)$ , where:*

- *i* is the rank order statistics
- *n* is the number of unmasked values along the given axis
- *alpha* and *beta* are two parameters.

*Typical values for alpha and beta are:*

- (0,1) :  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)

- (.5,.5) :  $p(k) = (k-1/2.) / n$ , piecewise linear function (R, type 5)
- (0,0) :  $p(k) = k / (n+1)$ , Weibull (R type 6)
- (1,1) :  $p(k) = (k-1) / (n-1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k-1/3) / (n+1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (R type 8)
- (3/8,3/8):  $p(k) = (k-3/8) / (n+1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (R type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

**data** : array\_like  
Input data, as a sequence or array of dimension at most 2.

**alpha** : float, optional  
Plotting positions parameter. Default is 0.4.

**beta** : float, optional  
Plotting positions parameter. Default is 0.4.

**Returns**

**positions** : MaskedArray  
The calculated plotting positions.

`scipy.stats.mstats.mode(a, axis=0)`

Returns an array of the modal (most common) value in the passed array.

**Parameters**

**a** : array\_like  
n-dimensional array of which to find mode(s).

**axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array  $a$ .

**Returns**

**mode** : ndarray  
Array of modal values.

**count** : ndarray  
Array of counts for each mode.

**Notes**

For more details, see `stats.mode`.

`scipy.stats.mstats.moment(a, moment=1, axis=0)`

Calculates the  $n$ th moment about the mean for a sample.

**Parameters**

**a** : array\_like  
data

**moment** : int, optional  
order of central moment that is returned

**axis** : int or None, optional  
Axis along which the central moment is computed. Default is 0. If None, compute over the whole array  $a$ .

**Returns**

**$n$ -th central moment** : ndarray or float  
The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**Notes**

For more details about `moment`, see `stats.moment`.

`scipy.stats.mstats.mquantiles(a, prob=[0.25, 0.5, 0.75], alphap=0.4, betap=0.4, axis=None, limit=())`

Computes empirical quantiles for a data array.

Samples quantile are defined by  $Q(p) = (1-\gamma) * x[j] + \gamma * x[j+1]$ , where  $x[j]$  is the  $j$ -th order statistic, and  $\gamma$  is a function of  $j = \text{floor}(n * p + m)$ ,  $m = \text{alphap} + p * (1 - \text{alphap} - \text{betap})$  and  $g = n * p + m - j$ .

Reinterpreting the above equations to compare to **R** lead to the equation:  $p(k) = (k - \text{alphap}) / (n + 1 - \text{alphap} - \text{betap})$

*Typical values of (alphap,betap) are:*

- (0,1):  $p(k) = k/n$ : linear interpolation of cdf (**R** type 4)
- (.5,.5):  $p(k) = (k - 1/2.) / n$ : piecewise linear function (**R** type 5)
- (0,0):  $p(k) = k / (n+1)$ : (**R** type 6)
- (1,1):  $p(k) = (k-1) / (n-1)$ :  $p(k) = \text{mode}[F(x[k])]$ . (**R** type 7, **R** default)
- (1/3,1/3):  $p(k) = (k-1/3) / (n+1/3)$ : Then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (**R** type 8)
- (3/8,3/8):  $p(k) = (k-3/8) / (n+1/4)$ : Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (**R** type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM

**Parameters** **a**: array\_like

Input data, as a sequence or array of dimension at most 2.

**prob**: array\_like, optional

List of quantiles to compute.

**alphap**: float, optional

Plotting positions parameter, default is 0.4.

**betap**: float, optional

Plotting positions parameter, default is 0.4.

**axis**: int, optional

Axis along which to perform the trimming. If None (default), the input array is first flattened.

**limit**: tuple, optional

Tuple of (lower, upper) values. Values of  $a$  outside this open interval are ignored.

**Returns** **mquantiles**: `MaskedArray`

An array containing the calculated quantiles.

### Notes

This formulation is very similar to **R** except the calculation of  $m$  from `alphap` and `betap`, where in **R**  $m$  is defined with each type.

### References

[R673], [R674]

### Examples

```
>>> from scipy.stats.mstats import mquantiles
>>> a = np.array([6., 47., 49., 15., 42., 41., 7., 39., 43., 40., 36.])
>>> mquantiles(a)
array([ 19.2,  40. ,  42.8])
```

Using a 2D array, specifying axis and limit.

```
>>> data = np.array([[ 6.,  7.,  1.],
...                  [ 47., 15.,  2.],
...                  [ 49., 36.,  3.],
...                  [ 15., 39.,  4.],
...                  [ 42., 40., -999.],
...                  [ 41., 41., -999.],
...                  [  7., -999., -999.],
...                  [ 39., -999., -999.],
...                  [ 43., -999., -999.],
...                  [ 40., -999., -999.],
...                  [ 36., -999., -999.]])
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[ 19.2  14.6  1.45]
 [ 40.   37.5  2.5 ]
 [ 42.8  40.05 3.55]]
```

```
>>> data[:, 2] = -999.
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.200000000000003 14.6 --]
 [40.0 37.5 --]
 [42.800000000000004 40.05 --]]
```

`scipy.stats.mstats.msign(x)`

Returns the sign of x, or 0 if x is masked.

`scipy.stats.mstats.normaltest(a, axis=0)`

Tests whether a sample differs from a normal distribution.

**Parameters** **a** : array\_like

The array containing the data to be tested.

**axis** : int or None, optional

Axis along which to compute test. Default is 0. If None, compute over the

**Returns** **statistic** : float or array

whole array *a*.  
 $s^2 + k^2$ , where *s* is the z-score returned by *skewtest* and *k* is the z-score returned by *kurtosistest*.

**pvalue** : float or array

A 2-sided chi squared probability for the hypothesis test.

**Notes**

For more details about *normaltest*, see *stats.normaltest*.

`scipy.stats.mstats.obrientransform(*args)`

Computes a transform on input data (any number of columns). Used to test for homogeneity of variance prior to running one-way stats. Each array in *\*args* is one level of a factor. If an *f\_oneway()* run on the transformed data and found significant, variances are unequal. From Maxwell and Delaney, p.112.

Returns: transformed data for use in an ANOVA

`scipy.stats.mstats.pearsonr(x, y)`

Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson's correlation requires that each dataset be normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters** **x** : 1-D array\_like  
Input  
**y** : 1-D array\_like  
Input  
**Returns** **pearsonr** : float  
Pearson's correlation coefficient, 2-tailed p-value.

### References

<http://www.statsoft.com/textbook/glosp.html#Pearson%20Correlation>

`scipy.stats.mstats.pointbiserialr` (*x*, *y*)

Calculates a point biserial correlation coefficient and its p-value.

**Parameters** **x** : array\_like of bools  
Input array.  
**y** : array\_like  
Input array.  
**Returns** **correlation** : float  
R value  
**pvalue** : float  
2-tailed p-value

### Notes

Missing values are considered pair-wise: if a value is missing in *x*, the corresponding value in *y* is masked.

For more details on `pointbiserialr`, see `stats.pointbiserialr`.

`scipy.stats.mstats.rankdata` (*data*, *axis=None*, *use\_missing=False*)

Returns the rank (also known as order statistics) of each data point along the given axis.

If some values are tied, their rank is averaged. If some values are masked, their rank is set to 0 if `use_missing` is False, or set to the average rank of the unmasked values if `use_missing` is True.

**Parameters** **data** : sequence  
Input data. The data is transformed to a masked array  
**axis** : {None,int}, optional  
Axis along which to perform the ranking. If None, the array is first flattened. An exception is raised if the axis is specified for arrays with a dimension larger than 2  
**use\_missing** : bool, optional  
Whether the masked values have a rank of 0 (False) or equal to the average rank of the unmasked values (True).

`scipy.stats.mstats.scoreatpercentile` (*data*, *per*, *limit=()*, *alphap=0.4*, *betap=0.4*)

Calculate the score at the given 'per' percentile of the sequence *a*. For example, the score at `per=50` is the median.

This function is a shortcut to `mquantile`

`scipy.stats.mstats.sem` (*a*, *axis=0*, *ddof=1*)

Calculates the standard error of the mean of the input array.

Also sometimes called standard error of measurement.

**Parameters** **a** : array\_like  
An array containing the values for which the standard error is returned.

**axis** : int or None, optional  
 If axis is None, ravel *a* first. If axis is an integer, this will be the axis over which to operate. Defaults to 0.

**ddof** : int, optional  
 Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

**Returns** **s** : ndarray or float  
 The standard error of the mean in the sample(s), along the input axis.

**Notes**

The default value for *ddof* changed in scipy 0.15.0 to be consistent with *stats.sem* as well as with the most common definition used (like in the R documentation).

**Examples**

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5, 4)
>>> print(stats.mstats.sem(a))
[2.8284271247461903  2.8284271247461903  2.8284271247461903
 2.8284271247461903]
```

Find standard error across the whole array, using n degrees of freedom:

```
>>> print(stats.mstats.sem(a, axis=None, ddof=0))
1.2893796958227628
```

`scipy.stats.mstats.skew(a, axis=0, bias=True)`

Computes the skewness of a data set.

**Parameters** **a** : ndarray  
 data

**axis** : int or None, optional  
 Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.

**bias** : bool, optional  
 If False, then the calculations are corrected for statistical bias.

**Returns** **skewness** : ndarray  
 The skewness of values along an axis, returning 0 where all values are equal.

**Notes**

For more details about *skew*, see *stats.skew*.

`scipy.stats.mstats.skewtest(a, axis=0)`

Tests whether the skew is different from the normal distribution.

**Parameters** **a** : array  
 The data to be tested

**axis** : int or None, optional  
 Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.

**Returns** **statistic** : float  
 The computed z-score for this test.

**pvalue** : float  
 a 2-sided p-value for the hypothesis test

**Notes**

For more details about `skewtest`, see `stats.skewtest`.

`scipy.stats.mstats.spearmanr(x, y, use_ties=True)`

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the linear relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a monotonic relationship. Positive correlations imply that as  $x$  increases, so does  $y$ . Negative correlations imply that as  $x$  increases,  $y$  decreases.

Missing values are discarded pair-wise: if a value is missing in  $x$ , the corresponding value in  $y$  is masked.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

<b>Parameters</b>	<b>x</b> : array_like	The length of $x$ must be $> 2$ .
	<b>y</b> : array_like	The length of $y$ must be $> 2$ .
<b>Returns</b>	<b>use_ties</b> : bool, optional	Whether the correction for ties should be computed.
	<b>correlation</b> : float	Spearman correlation coefficient
	<b>pvalue</b> : float	2-tailed p-value.

**References**

[CRCProbStat2000] section 14.7

`scipy.stats.mstats.theilslopes(y, x=None, alpha=0.95)`

Computes the Theil-Sen estimator for a set of points  $(x, y)$ .

`theilslopes` implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

<b>Parameters</b>	<b>y</b> : array_like	Dependent variable.
	<b>x</b> : array_like or None, optional	Independent variable. If None, use <code>arange(len(y))</code> instead.
<b>Returns</b>	<b>alpha</b> : float, optional	Confidence degree between 0 and 1. Default is 95% confidence. Note that $\alpha$ is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.
	<b>medslope</b> : float	Theil slope.
	<b>medintercept</b> : float	Intercept of the Theil line, as $\text{median}(y) - \text{medslope} * \text{median}(x)$ .
	<b>lo_slope</b> : float	Lower bound of the confidence interval on <code>medslope</code> .
	<b>up_slope</b> : float	Upper bound of the confidence interval on <code>medslope</code> .

*Notes*

For more details on *theilslopes*, see *stats.theilslopes*.

`scipy.stats.mstats.tmax` (*a*, *upperlimit=None*, *axis=0*, *inclusive=True*)

Compute the trimmed maximum

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- a** : array\_like  
array of values
- upperlimit** : None or float, optional  
Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** : {True, False}, optional  
This flag determines whether values exactly equal to the upper limit are included. The default value is True.

**Returns**

- tmax** : float, int or ndarray

*Notes*

For more details on *tmax*, see *stats.tmax*.

`scipy.stats.mstats.tmean` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=None*)

Compute the trimmed mean.

**Parameters**

- a** : array\_like  
Array of values.
- limits** : None or (lower limit, upper limit), optional  
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
- inclusive** : (bool, bool), optional  
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** : int or None, optional  
Axis along which to operate. If None, compute over the whole array. Default is None.

**Returns**

- tmean** : float

*Notes*

For more details on *tmean*, see *stats.tmean*.

`scipy.stats.mstats.tmin` (*a*, *lowerlimit=None*, *axis=0*, *inclusive=True*)

Compute the trimmed minimum

**Parameters**

- a** : array\_like  
array of values
- lowerlimit** : None or float, optional  
Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional

Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**inclusive** : {True, False}, optional

This flag determines whether values exactly equal to the lower limit are included. The default value is True.

**Returns** **tmin** : float, int or ndarray

### Notes

For more details on *tmin*, see *stats.tmin*.

`scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True), relative=False, axis=None)`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters** **a** : sequence

Input array

**limits** : {None, tuple}, optional

If *relative* is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked.

If *relative* is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.

Noting *n* the number of unmasked data before trimming, the (*n*\*limits[0])th smallest data and the (*n*\*limits[1])th largest data are masked, and the total number of unmasked data after trimming is *n*\*(1.-sum(limits)) In each case, the value of one limit can be set to None to indicate an open interval.

If limits is None, no trimming is performed

**inclusive** : {(bool, bool) tuple}, optional

If *relative* is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If *relative* is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

**relative** : bool, optional

Whether to consider the limits as absolute values (False) or proportions to cut (True).

**axis** : int, optional

Axis along which to trim.

### Examples

```
>>> from scipy.stats.mstats import trim
>>> z = [ 1, 2, 3, 4, 5, 6, 7, 8, 9,10]
>>> print(trim(z, (3,8)))
[-- -- 3 4 5 6 7 8 -- --]
>>> print(trim(z, (0.1,0.2), relative=True))
[-- 2 3 4 5 6 7 8 -- --]
```

`scipy.stats.mstats.trima(a, limits=None, inclusive=(True, True))`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters** **a** : array\_like

Input array.

**limits** : {None, tuple}, optional

Tuple of (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit will be masked. A limit is None indicates an open interval.

**inclusive** : (bool, bool) tuple, optional

Tuple of (lower flag, upper flag), indicating whether values exactly equal to the lower (upper) limit are allowed.

`scipy.stats.mstats.trimboth` (*data*, *proportiontocut*=0.2, *inclusive*=(*True*, *True*), *axis*=*None*)

Trims the smallest and largest data values.

Trims the *data* by masking the `int`(`proportiontocut * n`) smallest and `int`(`proportiontocut * n`) largest values of data along the given axis, where *n* is the number of unmasked values before trimming.

**Parameters**    **data** : ndarray

Data to trim.

**proportiontocut** : float, optional

Percentage of trimming (as a float between 0 and 1). If *n* is the number of unmasked values before trimming, the number of values after trimming is  $(1 - 2 * \text{proportiontocut}) * n$ . Default is 0.2.

**inclusive** : {(bool, bool) tuple}, optional

Tuple indicating whether the number of data being masked on each side should be rounded (*True*) or truncated (*False*).

**axis** : int, optional

Axis along which to perform the trimming. If *None*, the input array is first flattened.

`scipy.stats.mstats.trimmed_stde` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *axis*=*None*)

Returns the standard error of the trimmed mean along the given axis.

**Parameters**    **a** : sequence

Input array

**limits** : {(0.1,0.1), tuple of float}, optional

tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.

If *n* is the number of unmasked data before trimming, the values smaller than  $n * \text{limits}[0]$  and the values larger than  $n * \text{limits}[1]$  are masked, and the total number of unmasked data after trimming is  $n * (1 - \text{sum}(\text{limits}))$ . In each case, the value of one limit can be set to *None* to indicate an open interval. If *limits* is *None*, no trimming is performed.

**inclusive** : {(bool, bool) tuple} optional

Tuple indicating whether the number of data being masked on each side should be rounded (*True*) or truncated (*False*).

**axis** : int, optional

Axis along which to trim.

**Returns**    **trimmed\_stde** : scalar or ndarray

`scipy.stats.mstats.trimr` (*a*, *limits*=*None*, *inclusive*=(*True*, *True*), *axis*=*None*)

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

**Parameters**    **a** : sequence

Input array.

**limits** : {None, tuple}, optional

Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting *n* the number of unmasked data before trimming, the  $(n * \text{limits}[0])$ th smallest data and the  $(n * \text{limits}[1])$ th largest data are masked, and the total number of unmasked

data after trimming is  $n*(1.-\text{sum}(\text{limits}))$ . The value of one limit can be set to None to indicate an open interval.

**inclusive** : {(True,True) tuple}, optional

Tuple of flags indicating whether the number of data being masked on the left (right) end should be truncated (True) or rounded (False) to integers.

**axis** : {None,int}, optional

Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

`scipy.stats.mstats.trimtail` (*data*, *proportiontocut*=0.2, *tail*='left', *inclusive*=(True, True), *axis*=None)

Trims the data by masking values from one tail.

**Parameters** **data** : array\_like

Data to trim.

**proportiontocut** : float, optional

Percentage of trimming. If *n* is the number of unmasked values before trimming, the number of values after trimming is  $(1 - \text{proportiontocut}) * n$ . Default is 0.2.

**tail** : {'left','right'}, optional

If 'left' the *proportiontocut* lowest values will be masked. If 'right' the *proportiontocut* highest values will be masked. Default is 'left'.

**inclusive** : {(bool, bool) tuple}, optional

Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Default is (True, True).

**axis** : int, optional

Axis along which to perform the trimming. If None, the input array is first flattened. Default is None.

**Returns** **trimtail** : ndarray

Returned array of same shape as *data* with masked tail values.

`scipy.stats.mstats.tsem` (*a*, *limits*=None, *inclusive*=(True, True), *axis*=0, *ddof*=1)

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

**Parameters** **a** : array\_like

array of values

**limits** : None or (lower limit, upper limit), optional

Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** : (bool, bool), optional

A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** : int or None, optional

Axis along which to operate. If None, compute over the whole array. Default is zero.

**ddof** : int, optional

Delta degrees of freedom. Default is 1.

**Returns** **tsem** : float

### Notes

For more details on *tsem*, see *stats.tsem*.

`scipy.stats.mstats.ttest_onesamp` (*a*, *popmean*, *axis=0*)

Calculates the T-test for the mean of ONE group of scores.

**Parameters**

- a** : array\_like  
sample observation
- popmean** : float or array\_like  
expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension
- axis** : int or None, optional  
Axis along which to compute test. If None, compute over the whole array

**Returns**

- statistic** : float or array  
*a*.  
t-statistic
- pvalue** : float or array  
two-tailed p-value

**Notes**

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

`scipy.stats.mstats.ttest_ind` (*a*, *b*, *axis=0*, *equal\_var=True*)

Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

**Parameters**

- a, b** : array\_like  
The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).
- axis** : int or None, optional  
Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.
- equal\_var** : bool, optional  
If True, perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch's t-test, which does not assume equal population variance. .. versionadded:: 0.17.0

**Returns**

- statistic** : float or array  
The calculated t-statistic.
- pvalue** : float or array  
The two-tailed p-value.

**Notes**

For more details on `ttest_ind`, see `stats.ttest_ind`.

`scipy.stats.mstats.ttest_rel` (*a*, *b*, *axis=0*)

Calculates the T-test on TWO RELATED samples of scores, *a* and *b*.

**Parameters**

- a, b** : array\_like  
The arrays must have the same shape.
- axis** : int or None, optional  
Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.

**Returns**

- statistic** : float or array  
t-statistic
- pvalue** : float or array  
two-tailed p-value

**Notes**

For more details on `ttest_rel`, see `stats.ttest_rel`.

`scipy.stats.mstats.tvar` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)

Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

**Parameters**

- a** : array\_like  
Array of values.
- limits** : None or (lower limit, upper limit), optional  
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- inclusive** : (bool, bool), optional  
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** : int or None, optional  
Axis along which to operate. If None, compute over the whole array. Default is zero.
- ddof** : int, optional  
Delta degrees of freedom. Default is 1.

**Returns**

- tvar** : float  
Trimmed variance.

#### Notes

For more details on *tvar*, see *stats.tvar*.

`scipy.stats.mstats.variation` (*a*, *axis=0*)

Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.

**Parameters**

- a** : array\_like  
Input array.
- axis** : int or None, optional  
Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.

**Returns**

- variation** : ndarray  
The calculated variation along the requested axis.

#### Notes

For more details about *variation*, see *stats.variation*.

`scipy.stats.mstats.winsorize` (*a*, *limits=None*, *inclusive=(True, True)*, *inplace=False*, *axis=None*)

Returns a Winsorized version of the input array.

The (*limits*[0])th lowest values are set to the (*limits*[0])th percentile, and the (*limits*[1])th highest values are set to the (1 - *limits*[1])th percentile. Masked values are skipped.

**Parameters**

- a** : sequence  
Input array.
- limits** : {None, tuple of float}, optional  
Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting *n* the number of unmasked data before trimming, the (*n*\**limits*[0])th smallest data and the (*n*\**limits*[1])th largest data are masked, and the total number of unmasked data after trimming is *n*\*(1.-sum(*limits*)). The value of one limit can be set to None to indicate an open interval.

**inclusive** : {(True, True) tuple}, optional  
 Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

**inplace** : {False, True}, optional  
 Whether to winsorize in place (True) or to use a copy (False)

**axis** : {None, int}, optional  
 Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

**Notes**

This function is applied to reduce the effect of possibly spurious outliers by limiting the extreme values.

`scipy.stats.mstats.zmap(scores, compare, axis=0, ddof=0)`

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

**Parameters**

- scores** : array\_like  
 The input for which z-scores are calculated.
- compare** : array\_like  
 The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as *scores*.
- axis** : int or None, optional  
 Axis over which mean and variance of *compare* are calculated. Default is 0. If None, compute over the whole array *scores*.
- ddof** : int, optional  
 Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- zscore** : array\_like  
 Z-scores, in the same shape as *scores*.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

**Examples**

```

>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017,  0.          ,  0.35355339,  0.70710678])
    
```

`scipy.stats.mstats.zscore(a, axis=0, ddof=0)`

Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

**Parameters**

- a** : array\_like  
 An array like object containing the sample data.
- axis** : int or None, optional  
 Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** : int, optional  
 Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- zscore** : array\_like  
 The z-scores, standardized by mean and standard deviation of input array *a*.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

**Examples**

```
>>> a = np.array([ 0.7972,  0.0767,  0.4383,  0.7866,  0.8091,
...               0.1954,  0.6307,  0.6599,  0.1065,  0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```
>>> b = np.array([[ 0.3148,  0.0478,  0.6243,  0.4608],
...               [ 0.7149,  0.0775,  0.6072,  0.9656],
...               [ 0.6341,  0.1403,  0.9759,  0.4064],
...               [ 0.5918,  0.6948,  0.904 ,  0.3721],
...               [ 0.0921,  0.2481,  0.1188,  0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[ -0.19264823, -1.28415119,  1.07259584,  0.40420358],
       [  0.33048416, -1.37380874,  0.04251374,  1.00081084],
       [  0.26796377, -1.12598418,  1.23283094, -0.37481053],
       [ -0.22095197,  0.24468594,  1.19042819, -1.21416216],
       [ -0.82780366,  1.4457416 , -0.43867764, -0.1792603 ]])
```

`scipy.stats.mstats.compare_medians_ms(group_1, group_2, axis=None)`

Compares the medians from two independent groups along the given axis.

The comparison is performed using the McKean-Schrader estimate of the standard error of the medians.

**Parameters** **group\_1** : array\_like

First dataset. Has to be of size  $\geq 7$ .

**group\_2** : array\_like

Second dataset. Has to be of size  $\geq 7$ .

**axis** : int, optional

Axis along which the medians are estimated. If None, the arrays are flattened. If *axis* is not None, then *group\_1* and *group\_2* should have the same

**Returns** **compare\_medians\_ms** : {float, ndarray}

If *axis* is None, then returns a float, otherwise returns a 1-D ndarray of floats with a length equal to the length of *group\_1* along *axis*.

`scipy.stats.mstats.gmean(a, axis=0, dtype=None)`

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is:  $n$ -th root of  $(x_1 * x_2 * \dots * x_n)$

**Parameters** **a** : array\_like

Input array or object that can be converted to an array.

**axis** : int or None, optional

Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array *a*.

**dtype** : dtype, optional

Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of *a*, unless a

**Returns** **gmean** : ndarray  
 has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.  
 see dtype parameter above

**See also:**

**numpy.mean** Arithmetic average  
**numpy.average** Weighted average  
**hmean** Harmonic mean

**Notes**

The geometric average is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

**Examples**

```
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

scipy.stats.mstats.**hdmedian** (*data, axis=-1, var=False*)

Returns the Harrell-Davis estimate of the median along the given axis.

**Parameters** **data** : ndarray  
 Data array.  
**axis** : int, optional  
 Axis along which to compute the quantiles. If None, use a flattened array.  
**var** : bool, optional  
 Whether to return the variance of the estimate.  
**Returns** **hdmedian** : MaskedArray  
 The median values. If var=True, the variance is returned inside the masked array. E.g. for a 1-D array the shape change from (1,) to (2,).

scipy.stats.mstats.**hdquantiles** (*data, prob=[0.25, 0.5, 0.75], axis=None, var=False*)

Computes quantile estimates with the Harrell-Davis method.

The quantile estimates are calculated as a weighted linear combination of order statistics.

**Parameters** **data** : array\_like  
 Data array.  
**prob** : sequence, optional  
 Sequence of quantiles to compute.  
**axis** : int or None, optional  
 Axis along which to compute the quantiles. If None, use a flattened array.  
**var** : bool, optional  
 Whether to return the variance of the estimate.  
**Returns** **hdquantiles** : MaskedArray  
 A (p,) array of quantiles (if var is False), or a (2,p) array of quantiles and variances (if var is True), where p is the number of quantiles.

**See also:**

*hdquantiles\_sd*

`scipy.stats.mstats.hdquantiles_sd` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

The standard error of the Harrell-Davis quantile estimates by jackknife.

**Parameters**

- data** : array\_like  
Data array.
- prob** : sequence, optional  
Sequence of quantiles to compute.
- axis** : int, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

- hdquantiles\_sd** : MaskedArray  
Standard error of the Harrell-Davis quantile estimates.

**See also:**

`hdquantiles`

`scipy.stats.mstats.hmean` (*a*, *axis*=0, *dtype*=None)

Calculate the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

**Parameters**

- a** : array\_like  
Input array, masked array or object that can be converted to an array.
- axis** : int or None, optional  
Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** : dtype, optional  
Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer *dtype* with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- hmean** : ndarray  
see *dtype* parameter above

**See also:**

`numpy.mean` Arithmetic average

`numpy.average`

Weighted average

`gmean` Geometric mean

**Notes**

The harmonic mean is computed over a single dimension of the input array, *axis*=0 by default, or all values in the array if *axis*=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

**Examples**

```
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

`scipy.stats.mstats.idealfourths` (*data*, *axis*=None)

Returns an estimate of the lower and upper quartiles.

Uses the ideal fourths algorithm.

**Parameters** **data** : array\_like  
 Input array.  
**axis** : int, optional  
 Axis along which the quartiles are estimated. If None, the arrays are flattened.

**Returns** **idealfourths** : {list of floats, masked array}  
 Returns the two internal values that divide *data* into four parts using the ideal fourths algorithm either along the flattened array (if *axis* is None) or along *axis* of *data*.

`scipy.stats.mstats.kruskal(*args)`  
 Compute the Kruskal-Wallis H-test for independent samples

**Parameters** **sample1, sample2, ...** : array\_like  
 Two or more arrays with the sample measurements can be given as arguments.

**Returns** **statistic** : float  
 The Kruskal-Wallis H statistic, corrected for ties  
**pvalue** : float  
 The p-value for the test using the assumption that H has a chi square distribution

**Notes**

For more details on *kruskal*, see *stats.kruskal*.

`scipy.stats.mstats.ks_2samp(data1, data2, alternative='two-sided')`  
 Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

**Parameters** **data1** : array\_like  
 First data set  
**data2** : array\_like  
 Second data set  
**alternative** : {‘two-sided’, ‘less’, ‘greater’}, optional  
 Indicates the alternative hypothesis. Default is ‘two-sided’.

**Returns** **d** : float  
 Value of the Kolmogorov Smirnov test  
**p** : float  
 Corresponding p-value.

`scipy.stats.mstats.median_cihs(data, alpha=0.05, axis=None)`  
 Computes the alpha-level confidence interval for the median of the data.

Uses the Hettmasperger-Sheather method.

**Parameters** **data** : array\_like  
 Input data. Masked values are discarded. The input should be 1D only, or *axis* should be set to None.  
**alpha** : float, optional  
 Confidence level of the intervals.  
**axis** : int or None, optional  
 Axis along which to compute the quantiles. If None, use a flattened array.

**Returns** **median\_cihs**  
 Alpha level confidence interval.

`scipy.stats.mstats.meppf(data, alpha=0.4, beta=0.4)`  
 Returns plotting positions (or empirical percentile points) for the data.  
 Plotting positions are defined as  $(i - \alpha) / (n + 1 - \alpha - \beta)$ , where:

- $i$  is the rank order statistics
- $n$  is the number of unmasked values along the given axis
- $\alpha$  and  $\beta$  are two parameters.

*Typical values for alpha and beta are:*

- (0,1) :  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5) :  $p(k) = (k-1/2)/n$ , piecewise linear function (R, type 5)
- (0,0) :  $p(k) = k/(n+1)$ , Weibull (R type 6)
- (1,1) :  $p(k) = (k-1)/(n-1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k-1/3)/(n+1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (R type 8)
- (3/8,3/8):  $p(k) = (k-3/8)/(n+1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (R type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

**data** : array\_like  
Input data, as a sequence or array of dimension at most 2.

**alpha** : float, optional  
Plotting positions parameter. Default is 0.4.

**beta** : float, optional  
Plotting positions parameter. Default is 0.4.

**Returns**

**positions** : MaskedArray  
The calculated plotting positions.

`scipy.stats.mstats.mjci` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

**Parameters**

**data** : ndarray  
Data array.

**prob** : sequence, optional  
Sequence of quantiles to compute.

**axis** : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

`scipy.stats.mstats.mquantiles_cimj` (*data*, *prob*=[0.25, 0.5, 0.75], *alpha*=0.05, *axis*=None)

Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.

**Parameters**

**data** : ndarray  
Data array.

**prob** : sequence, optional  
Sequence of quantiles to compute.

**alpha** : float, optional  
Confidence level of the intervals.

**axis** : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

**ci\_lower** : ndarray  
The lower boundaries of the confidence interval. Of the same length as *prob*.

**ci\_upper** : ndarray  
The upper boundaries of the confidence interval. Of the same length as *prob*.

`scipy.stats.mstats.rsh` (*data*, *points=None*)

Evaluates Rosenblatt's shifted histogram estimators for each data point.

Rosenblatt's estimator is a centered finite-difference approximation to the derivative of the empirical cumulative distribution function.

**Parameters** **data** : sequence

Input data, should be 1-D. Masked values are ignored.

**points** : sequence or None, optional

Sequence of points where to evaluate Rosenblatt shifted histogram. If None, use the data.

`scipy.stats.mstats.sen_seasonal_slopes` (*x*)

`scipy.stats.mstats.trimmed_mean` (*a*, *limits=(0.1, 0.1)*, *inclusive=(1, 1)*, *relative=True*, *axis=None*)

`scipy.stats.mstats.trimmed_mean_ci` (*data*, *limits=(0.2, 0.2)*, *inclusive=(True, True)*, *alpha=0.05*, *axis=None*)

Selected confidence interval of the trimmed mean along the given axis.

**Parameters** **data** : array\_like

Input data.

**limits** : {None, tuple}, optional

None or a two item tuple. Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. If *n* is the number of unmasked data before trimming, then (*n* \* *limits*[0])th smallest data and (*n* \* *limits*[1])th largest data are masked. The total number of unmasked data after trimming is *n* \* (1. - sum(*limits*)). The value of one limit can be set to None to indicate an open interval.

Defaults to (0.2, 0.2).

**inclusive** : (2,) tuple of boolean, optional

If *relative==False*, tuple indicating whether values exactly equal to the absolute limits are allowed. If *relative==True*, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

Defaults to (True, True).

**alpha** : float, optional

Confidence level of the intervals.

Defaults to 0.05.

**axis** : int, optional

Axis along which to cut. If None, uses a flattened version of *data*.

Defaults to None.

**Returns** **trimmed\_mean\_ci** : (2,) ndarray

The lower and upper confidence intervals of the trimmed data.

`scipy.stats.mstats.trimmed_std` (*a*, *limits=(0.1, 0.1)*, *inclusive=(1, 1)*, *relative=True*, *axis=None*, *ddof=0*)

`scipy.stats.mstats.trimmed_var` (*a*, *limits=(0.1, 0.1)*, *inclusive=(1, 1)*, *relative=True*, *axis=None*, *ddof=0*)

`scipy.stats.mstats.ttest_1samp` (*a*, *popmean*, *axis=0*)

Calculates the T-test for the mean of ONE group of scores.

**Parameters** **a** : array\_like

sample observation

**popmean** : float or array\_like  
 expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension

**axis** : int or None, optional  
 Axis along which to compute test. If None, compute over the whole array

**Returns**

**statistic** : float or array  
<sup>*a*</sup>  
 t-statistic

**pvalue** : float or array  
 two-tailed p-value

**Notes**

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

### 5.27.9 Univariate and multivariate kernel density estimation (`scipy.stats.kde`)

`gaussian_kde(dataset[, bw_method])` Representation of a kernel-density estimate using Gaussian kernels.

**class** `scipy.stats.gaussian_kde` (*dataset*, *bw\_method=None*)  
 Representation of a kernel-density estimate using Gaussian kernels.

Kernel density estimation is a way to estimate the probability density function (PDF) of a random variable in a non-parametric way. `gaussian_kde` works for both uni-variate and multi-variate data. It includes automatic bandwidth determination. The estimation works best for a unimodal distribution; bimodal or multi-modal distributions tend to be oversmoothed.

**Parameters**

**dataset** : array\_like  
 Datapoints to estimate from. In case of univariate data this is a 1-D array, otherwise a 2-D array with shape (# of dims, # of data).

**bw\_method** : str, scalar or callable, optional  
 The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), ‘scott’ is used. See Notes for more details.

**Notes**

Bandwidth selection strongly influences the estimate obtained from the KDE (much more so than the actual shape of the kernel). Bandwidth selection can be done by a “rule of thumb”, by cross-validation, by “plug-in methods” or by other means; see [R644], [R645] for reviews. `gaussian_kde` uses a rule of thumb, the default is Scott’s Rule.

Scott’s Rule [R642], implemented as `scotts_factor`, is:

```
n**(-1./ (d+4)),
```

with *n* the number of data points and *d* the number of dimensions. Silverman’s Rule [R643], implemented as `silverman_factor`, is:

```
(n * (d + 2) / 4.)**(-1. / (d + 4)).
```

Good general descriptions of kernel density estimation can be found in [R642] and [R643], the mathematics for this multi-dimensional implementation can be found in [R642].

### References

[R642], [R643], [R644], [R645]

### Examples

Generate some random two-dimensional data:

```
>>> from scipy import stats
>>> def measure(n):
...     "Measurement model, return two coupled measurements."
...     m1 = np.random.normal(size=n)
...     m2 = np.random.normal(scale=0.5, size=n)
...     return m1+m2, m1-m2
```

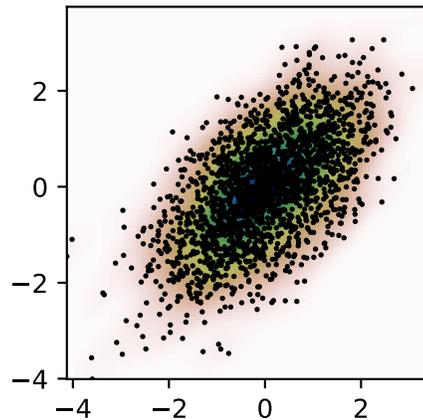

```
>>> m1, m2 = measure(2000)
>>> xmin = m1.min()
>>> xmax = m1.max()
>>> ymin = m2.min()
>>> ymax = m2.max()
```

Perform a kernel density estimate on the data:

```
>>> X, Y = np.mgrid[xmin:xmax:100j, ymin:ymax:100j]
>>> positions = np.vstack([X.ravel(), Y.ravel()])
>>> values = np.vstack([m1, m2])
>>> kernel = stats.gaussian_kde(values)
>>> Z = np.reshape(kernel(positions).T, X.shape)
```

Plot the results:

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.imshow(np.rot90(Z), cmap=plt.cm.gist_earth_r,
...          extent=[xmin, xmax, ymin, ymax])
>>> ax.plot(m1, m2, 'k.', markersize=2)
>>> ax.set_xlim([xmin, xmax])
>>> ax.set_ylim([ymin, ymax])
>>> plt.show()
```

### Attributes

dataset	(ndarray) The dataset with which <i>gaussian_kde</i> was initialized.
d	(int) Number of dimensions.
n	(int) Number of datapoints.
factor	(float) The bandwidth factor, obtained from <i>kde.covariance_factor</i> , with which the covariance matrix is multiplied.
covariance	(ndarray) The covariance matrix of <i>dataset</i> , scaled by the calculated bandwidth ( <i>kde.factor</i> ).
inv_cov	(ndarray) The inverse of <i>covariance</i> .

### Methods

<i>evaluate</i> (points)	Evaluate the estimated pdf on a set of points.
<i>__call__</i> (points)	Evaluate the estimated pdf on a set of points.
<i>integrate_gaussian</i> (mean, cov)	Multiply estimated density by a multivariate Gaussian and integrate over the whole space.
<i>integrate_box_1d</i> (low, high)	Computes the integral of a 1D pdf between two bounds.
<i>integrate_box</i> (low_bounds, high_bounds[, maxpts])	Computes the integral of a pdf over a rectangular interval.
<i>integrate_kde</i> (other)	Computes the integral of the product of this kernel density estimate with another.
<i>pdf</i> (x)	Evaluate the estimated pdf on a provided set of points.
<i>logpdf</i> (x)	Evaluate the log of the estimated pdf on a provided set of points.
<i>resample</i> ([size])	Randomly sample a dataset from the estimated pdf.
<i>set_bandwidth</i> ([bw_method])	Compute the estimator bandwidth with given method.
<i>covariance_factor</i> ()	Computes the coefficient ( <i>kde.factor</i> ) that multiplies the data covariance matrix to obtain the kernel covariance matrix.

`gaussian_kde.evaluate`(points)  
Evaluate the estimated pdf on a set of points.

**Parameters** **points** : (# of dimensions, # of points)-array  
 Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

**Returns** **values** : (# of points,)-array  
 The values at each point.

**Raises** **ValueError** : if the dimensionality of the input points is different than the dimensionality of the KDE.

`gaussian_kde.__call__(points)`

Evaluate the estimated pdf on a set of points.

**Parameters** **points** : (# of dimensions, # of points)-array  
 Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

**Returns** **values** : (# of points,)-array  
 The values at each point.

**Raises** **ValueError** : if the dimensionality of the input points is different than the dimensionality of the KDE.

`gaussian_kde.integrate_gaussian(mean, cov)`

Multiply estimated density by a multivariate Gaussian and integrate over the whole space.

**Parameters** **mean** : array\_like  
 A 1-D array, specifying the mean of the Gaussian.

**cov** : array\_like  
 A 2-D array, specifying the covariance matrix of the Gaussian.

**Returns** **result** : scalar  
 The value of the integral.

**Raises** **ValueError**  
 If the mean or covariance of the input Gaussian differs from the KDE's dimensionality.

`gaussian_kde.integrate_box_1d(low, high)`

Computes the integral of a 1D pdf between two bounds.

**Parameters** **low** : scalar  
 Lower bound of integration.

**high** : scalar  
 Upper bound of integration.

**Returns** **value** : scalar  
 The result of the integral.

**Raises** **ValueError**  
 If the KDE is over more than one dimension.

`gaussian_kde.integrate_box(low_bounds, high_bounds, maxpts=None)`

Computes the integral of a pdf over a rectangular interval.

**Parameters** **low\_bounds** : array\_like  
 A 1-D array containing the lower bounds of integration.

**high\_bounds** : array\_like  
 A 1-D array containing the upper bounds of integration.

**maxpts** : int, optional  
 The maximum number of points to use for integration.

**Returns** **value** : scalar  
 The result of the integral.

`gaussian_kde.integrate_kde(other)`

Computes the integral of the product of this kernel density estimate with another.

**Parameters** **other** : gaussian\_kde instance  
 The other kde.

**Returns** **value** : scalar  
 The result of the integral.

**Raises** **ValueError**

If the KDEs have different dimensionality.

`gaussian_kde.pdf(x)`

Evaluate the estimated pdf on a provided set of points.

#### Notes

This is an alias for `gaussian_kde.evaluate`. See the `evaluate` docstring for more details.

`gaussian_kde.logpdf(x)`

Evaluate the log of the estimated pdf on a provided set of points.

`gaussian_kde.resample(size=None)`

Randomly sample a dataset from the estimated pdf.

**Parameters** `size` : int, optional

The number of samples to draw. If not provided, then the size is the same as the underlying dataset.

**Returns** `resample` : (self.d, size) ndarray

The sampled dataset.

`gaussian_kde.set_bandwidth(bw_method=None)`

Compute the estimator bandwidth with given method.

The new bandwidth calculated after a call to `set_bandwidth` is used for subsequent evaluations of the estimated density.

**Parameters** `bw_method` : str, scalar or callable, optional

The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), nothing happens; the current `kde.covariance_factor` method is kept.

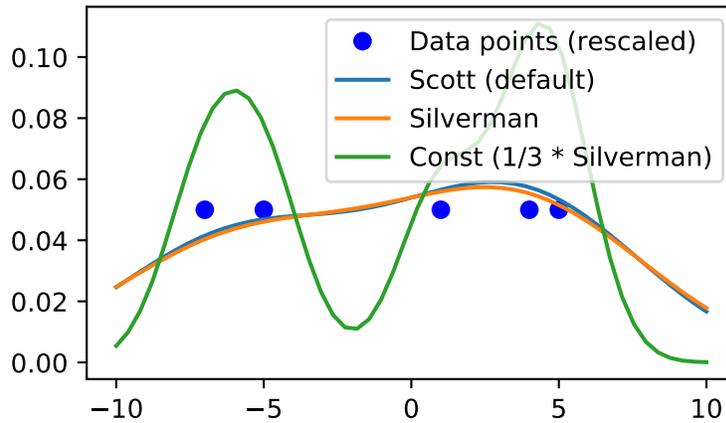

#### Notes

New in version 0.11.

#### Examples

```
>>> import scipy.stats as stats
>>> x1 = np.array([-7, -5, 1, 4, 5.])
>>> kde = stats.gaussian_kde(x1)
>>> xs = np.linspace(-10, 10, num=50)
>>> y1 = kde(xs)
>>> kde.set_bandwidth(bw_method='silverman')
>>> y2 = kde(xs)
>>> kde.set_bandwidth(bw_method=kde.factor / 3.)
>>> y3 = kde(xs)
```

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.plot(x1, np.ones(x1.shape) / (4. * x1.size), 'bo',
...        label='Data points (rescaled)')
>>> ax.plot(xs, y1, label='Scott (default)')
>>> ax.plot(xs, y2, label='Silverman')
>>> ax.plot(xs, y3, label='Const (1/3 * Silverman)')
>>> ax.legend()
>>> plt.show()
```

`gaussian_kde.covariance_factor()`

Computes the coefficient (*kde.factor*) that multiplies the data covariance matrix to obtain the kernel covariance matrix. The default is `scotts_factor`. A subclass can overwrite this method to provide a different method, or set it through a call to `kde.set_bandwidth`.

For many more stat related functions install the software R and the interface package rpy.

## 5.28 Low-level callback functions

Some functions in SciPy take as arguments callback functions, which can either be python callables or low-level compiled functions. Using compiled callback functions can improve performance somewhat by avoiding wrapping data in Python objects.

Such low-level functions in Scipy are wrapped in *LowLevelCallable* objects, which can be constructed from function pointers obtained from ctypes, cffi, Cython, or contained in Python *PyCapsule* objects.

*LowLevelCallable*

Low-level callback function.

**class** `scipy.LowLevelCallable`

Low-level callback function.

**Parameters**

- function** : {PyCapsule, ctypes function pointer, cffi function pointer}  
Low-level callback function.
- user\_data** : {PyCapsule, ctypes void pointer, cffi void pointer}  
User data to pass on to the callback function.
- signature** : str, optional  
Signature of the function. If omitted, determined from *function*, if possible.

### Notes

The argument *function* can be one of:

- PyCapsule, whose name contains the C function signature
- ctypes function pointer
- cffi function pointer

The signature of the low-level callback must match one of those expected by the routine it is passed to.

If constructing low-level functions from a PyCapsule, the name of the capsule must be the corresponding signature, in the format:

```
return_type (arg1_type, arg2_type, ...)
```

For example:

```
"void (double)"
"double (double, int *, void *)"
```

The context of a PyCapsule passed in as `function` is used as `user_data`, if an explicit value for `user_data` was not given.

**Attributes**

<code>function</code>	Callback function given
<code>user_data</code>	User data given
<code>signature</code>	Signature of the function.

**Methods**

`from_cython(module, name[, user_data, signature])` Create a low-level callback function from an exported Cython function.

**classmethod** `LowLevelCallable.from_cython(module, name, user_data=None, signature=None)`

Create a low-level callback function from an exported Cython function.

**Parameters**

- module** : module  
Cython module where the exported function resides
- name** : str  
Name of the exported function
- user\_data** : {PyCapsule, ctypes void pointer, cffi void pointer}, optional  
User data to pass on to the callback function.
- signature** : str, optional  
Signature of the function. If omitted, determined from *function*.

**See also:**

Functions accepting low-level callables:

`scipy.integrate.quad`, `scipy.ndimage.generic_filter`, `scipy.ndimage.generic_filter1d`, `scipy.ndimage.geometric_transform`

Usage examples:

*Extending scipy.ndimage in C, Faster integration using low-level callback functions*
